MISCELLANEOUS.

PERILS OF WHALE FISHERY.

In 1822, two boats belonging to the ship *Baffin*, went in pursuit of a whale. John Carr was harpooner and commander of one of them. The whale they pursued led them into a vast school of his own species; they were so numerous that their blowing was incessant, and they believed that they did not see fewer than an hundred. Fearful of alarming them without striking any, they remained for a while motionless. At last, one rose near Carr's boat, and he approached, and fatally for himself, harpooned it.

When he struck, the fish was approaching the boat; and passing very rapidly, jerked the line out of its place over the stern, and threw it upon the gunwale. Its pressure in this unfavorable position so careened the boat, that the side was pulled under water, and it began to fill.

In this emergency, Carr, who was a brave, active man, seized the line, and endeavored to relieve the boat by restoring it to its place; but, by some circumstance which was never accounted for, a turn of the line flew over his arm, dragged him overboard in an instant, and drew him under the water, never more to rise. So sudden was the accident, that only one man, who was watching him, saw what had happened; so that when the boat righted, which it immediately did, though half full of water, the whole crew on looking round, inquired what had become of Carr.

It is impossible to imagine a death more awfully sudden and unexpected. The invisible bullet could not have effected more instantaneous destruction. The velocity of the whale at its first descent, is from thirteen to fifteen feet per second. Now as this unfortunate man was adjusting the line at the water's very edge, where it must have been perfectly tight, owing to its obstruction in running out of the boat, the interval between the fastening of the line about him and his disappearance could not have exceeded the third part of a second of time, for in one second only he must have been dragged ten or twelve feet deep. Indeed, he had not time for the least exclamation; and the person who saw his removal, observed that it was exceeding quick, that though his eye was upon him at the moment, he could scarcely distinguish his figure as he disappeared.

A harpooner once succeeded in striking a whale which dragged out ten lines, (2400 yards,) and was supposed to be seen blowing in different holes in the ice. After some time it made its appearance on the exterior, and was again struck, at the moment it was about to go under the second time. About an hundred yards from the edge, it broke the ice where it was a foot thick, with its head, and respired through the opening. It then pushed forward, breaking the ice as it advanced, in spite of the lances constantly directed against it. At last it reached a kind of basin in the field, where it floated on the surface without any incumbrance from ice.

Its back being fairly exposed, the harpoon struck from the boat on the outside, was observed to be so slightly entangled, that it was ready to drop out.—Some of the officers lamented this circumstance, and wished that the harpoon might be better fast; at the same time observing that if it should slip out, either the fish would be lost, or they would be under the necessity of flinching it where it lay, and

of dragging the blubber over the ice to the ship; a kind and degree of labor every one was anxious to avoid.

No sooner was the wish expressed, and its importance explained, than a young and daring sailor stepped forward, and offered to strike the harpoon deeper. Not at all intimidated by the surprise manifested on every countenance at such a bold proposal, he leaped on the back of the living whale, and cut the harpoon out with his pocket knife. Stimulated by his gallant example, one of his companions proceeded to his assistance. While one of them hauled upon the line and held it in his hands, the other set his shoulder against the end of the harpoon, and though it was without a stock, contrived to strike it again into the fish more effectually than at first!

The whale was in motion before they had finished. After they got off its back, it advanced a considerable distance, breaking the ice all the way, and survived this novel treatment ten or fifteen minutes. This daring deed was of essential service. The whale fortunately sunk spontaneously after it expired; on which it was hauled out under the ice by the line, and secured without farther trouble. It proved a mighty whale,—a very considerable prize.

Captain Lyons while prosecuting the whale fishery on the Labrador coast, in the season of 1802, discovered a large whale at a short distance from the ship. Four boats were despatched in pursuit, and two of them succeeded in approaching it so closely together, that two harpoons were struck at the same moment. The fish descended a few fathoms in the direction of another of the boats which was on the advance, rose accidentally beneath it, struck it with its head, and threw the boat, men and apparatus about fifteen feet into the air. It was inverted by the stroke, and fell into the water with its keel upwards. All the people were picked up alive by the fourth boat, which was just at hand, excepting one man, who having got entangled in the boat, fell beneath it and was unfortunately drowned.

CONNECTICUT BLUE LAWS.

The following sketch of some of the laws made by the colony of New Haven, two hundred years ago, and denominated *Blue Laws* by the neighboring colonies, will give an idea of the spirit which pervades the whole.

No one shall be a freeman, or give a vote, unless he be converted and a member in full communion of one of the churches allowed in this Dominion.

No man shall hold any office who is not sound in the faith, and faithful to this Dominion; and whoever gives a vote to such a person, shall pay a fine of 2s: for a second offence he shall be disfranchised.

No quaker or dissenter from the established worship of this Dominion, shall be allowed to give a vote for the election of magistrate or any officer.

No food or lodging shall be afforded to a Quaker, Adamite, or other Heretic.

If any person turns Quaker, he shall be banished, and not suffered to return but upon pain of death.

No one shall run on Sunday, or walk in his garden or elsewhere, except reverently to and from meeting.

No one shall travel, cook victuals, make beds, sweep house, cut hair or shave on Sunday.

No woman shall kiss her child on Sunday or fasting day.

No one shall buy or sell lands without permission of the Selectmen.

No minister shall keep a mistress.

Whoever wears cloth trimmed with gold, silver or bone lace, above two shillings by the yard, shall be presented by the grand jurors, and the selectmen shall tax the offender at £300 estate.

A debtor in prison, swearing he has no estate shall be let out, and sold, to make satisfaction.

Whoever brings cards or dice into this Dominion shall pay a fine of 5s.

No priest shall abide in the Dominion; he shall be banished, and suffer death on his return.

Priests may be seized by any one without a warrant.

No one shall read common prayer, keep Christmas or Saints' days, make minced pies, dance, play cards, or play on any instrument of music, except the drum, trumpet, and jewsharp.

No man shall court a maid in person, or by letter, without first obtaining consent of her parents, £5 penalty for the first offence; £10 for the second; and for the third, imprisonment during the pleasure of the Court.

Married persons must live together or be imprisoned.

Every male shall have his hair cut round according to a cap.

Of such sort were the laws made by the people of New Haven, previous to their incorporation with Saybrook and Hartford colonies by the charter.—They consist of a vast multitude, and were very properly termed *Blue Laws*, i. e. *bloody laws*; for they were all sanctified with excommunication, confiscation, fines, banishment, whippings, cutting of the ears, burning the tongue, and death.

Useless Ornaments.—The New Orleans Pleasuranc has the following sensible touch at the cockney taste, or rather want of taste, which induce some people to load themselves with gimcrack ornaments. It says—

“We have about as high an opinion of the intellect of an Indian squaw who coils beads around her neck, or the good sense of an African who suspend brass rings from his nasal organ, as we have of the brainless fop who voluntarily enters the chain gang, and encumbers his person with baubles. Does a chain of gold, or one of diamonds, give brilliancy to the eye? Does a brooch of stained glass, the size of a carriage window, even though it be cornelean, add a tint to a blush of the cheek? The custom of wearing a superfluity of such gewgaw trinkets is abominable, and displays anything but good taste—particularly republican taste. He who is a slave of 6-by-4 inch breast pins, watch chain like the tiller rope of a Mississippi steamboat, or finger rings that would enchain a culprit, is, in our opinion, deficient of the necessary weight of brain—a man with a partially finished attic story.”

The best capital.—We hear much said in these days about capital—money capital—but the best of all capital for the young to start with in the world is a *good moral character*. This is but little talked of

AGRICULTURAL.

For the New England Farmer.

THE BILLAUDEAU CABBAGE.

MR COLMAN.—The Hon. Thomas L. Winthrop, recently placed in my hands an extract of a letter which he had received from France, and a Report made to the Royal Horticultural Society of Paris, a relation to an extraordinary Cabbage, with a request that I would translate the latter for the New England Farmer, which has been done and is enclosed.

Accompanying the letter were fine seeds,—one being the product of this remarkable new variety of cabbage, and the others of the celebrated species, called the Cavalier, which I was desired to present to some person for cultivation; that a careful experiment might be made, to ascertain whether either of the kinds could be reared in our climate, and would become a valuable acquisition to the country. They have been delivered to a gardener, who from his well known intelligence, practical skill and sincere devotion to all branches of rural economy, there cannot be a doubt but that every possible attention will be given to their culture, and he result reported to the Massachusetts Horticultural Society.

The active part which Governor Winthrop has taken, for nearly half a century, in all the measures which have been adopted, for the advancement of agricultural intelligence, and the exalted stations he has filled, with so much credit to himself and advantage to the State, have rendered his name familiar and dear to his fellow citizens. He was one of those enlightened and patriotic gentlemen who organized the first agricultural society in Massachusetts, for the especial purpose of promoting that highly important interest, and has ever since been zealous and unremitting in his laudable efforts to render that institution effectual, for all the great and useful objects of its establishment;—and we still find him the ardent friend of a cause, which he has done so much to advance; and that the introduction of even a few seeds, which may possibly become beneficial to his countrymen, is not deemed unworthy of this venerated Nestor of New England husbandry. May his illustrious example have its just influence upon the present and rising generations,—for the CULTIVATION OF THE EARTH is the grand basis of all the other branches of industry; and no nation can be considered truly INDEPENDENT, that does not produce all the ARTICLES OF FOOD, which are indispensable, for the SUPPORT OF THE WHOLE POPULATION.

With great respect, your

Most obt. servt.,

H. A. S. DEARBORN.

Hawthorn Cottage, Roxbury, Dec. 12, 1839.

Extract of a letter from a gentleman in Paris to the Hon. THOMAS L. WINTHROP.

"If I recollect rightly, you have a taste for Horticulture. I may mention then, that I have just

now seen a most curious plant, (shown to and admired by all the savants of Paris)—a mammoth Cabbage, 10 feet high and 52 feet circumference (French measure.) The Horticultural Society of Paris appointed a commission to examine this production and to verify its dimensions: they have made a report on all points, satisfactory to the proprietors of the plant. In that report they mention also, the "Choux cavalier," otherwise called "Choux a Vache"—and also "Choux en arbr," as being the largest known in France previous to the coming of this. This *Choux cavalier* I also saw by the side of the other. I suppose even this would be considered "mammoth" in the United States, for it is 5 1-2 feet high. As they will not add perceptibly to the bulk of this letter, I enclose one seed of the mammoth cabbage, and four of the Cavalier: it may be worth while to make an experiment with them; though it may be that the mammoth is a mere *lusus nature*: the proprietor himself does not feel confident that its seed will produce any thing like the present plant:—as to the Cavalier there is no doubt."

REPORT ON THE CABBAGE OF M. BILLAUDEAU,

Made to the Royal Horticultural Society of Paris, at a meeting held on the 14th of August, 1839. By a Committee composed of Messrs. Vilmorin, Jaques and Poiteau.

GENTLEMEN—Within a few days, there has been presented in Paris, to public curiosity, and those interested in the cultivation of the earth, a Cabbage, of an extraordinary character, both from its height and the number of its branches. This production must not be confounded with that marvellous fable which has excited public credulity during the last three years. Then the plant was not exhibited, and only the seeds were sold, which were to produce colossal cabbages. Those who may be apprehensive of becoming the dupes of a like kind of charlatanism, have nothing to fear in this case, for your commissioners have seen, touched and measured M. Billaudeau's cabbage, as have a great number of distinguished persons, and among them the Minister of Commerce and Agriculture. Besides, the commendable house which has possession of the Billaudeau Cabbage, would not, for any consideration, expose its reputation and its credit, by descending to a fraudulent speculation, like that which has disgraced the inventors of the Colossal Cabbage. This house is more desirous of the honor of having introduced to our cultivators a useful, new and extraordinary vegetable, than any profit which might be derived from the sale of its seeds.

The Messrs. Billaudeau have declared upon their honor, that they have never offered to sell this Cabbage or its seeds, to any person, and that whatever has been publicly said to the contrary, is utterly false. These gentlemen have been desirous of ascertaining what is the opinion of the Royal Horticultural Society, in relation to their Cabbage, that they may, in all respects, act in conformity to the views of that institution. You thus perceive,

gentlemen, that the Messrs Billaudeau have acted with impartiality and in good faith.

In conformity to the directions of the Society, we went on the eighth of this month to the house of M. Billaudeau, being No. 10, in the street des Prouvoires, to see and examine the Cabbage in question and to make a report to the society thereon.

We first discovered, that this Cabbage appeared to be in the third year of its growth, and that it was covered with ripe seeds. But by information since received, from the country, we learned that it was planted in August, 1837, and transplanted in October of the same year. We also learned that it was found among other cabbages in the district of Melle, and department of Deux-Sevres, where a vast number of cabbages are cultivated as food for cattle. The proprietor of the estate, having noticed the plant, he drew the attention of M. Billaudeau, the father, to it, who bestowed special attention to its culture, and was astonished at its enormous growth. When in flower, it rose like a Colossus above the neighboring plants. It occurred to M. Billaudeau, that this plant might be reproduced from the seed, and thus become a precious acquisition in rural economy, and that from its gigantic size, it merited the examination of those persons who felt a deep interest in the culture and physiology of plants: consequently, when the seeds were ripe, he took up the plant, and placing it carefully in a wagon, had it transported to Paris, and placed in the house of his sons, the Messrs. Billaudeau, who were his successors, as *deuxi* in seeds.

It was, therefore, in its state of fructification, that we have seen this marvellous vegetable, and to which the various public journals have already given the name of the Billaudeau Cabbage.

A Cavalier Cabbage, which is the largest hitherto known among our cultivators, placed for comparison near this, appeared a dwarf.

Since our first visit, M. Billaudeau, the father, has sent to his sons additional information, of which it is proper we should avail ourselves. In the first place, we were shown a small box of earth, which was taken from the spot where the cabbage grew. On examination it appeared to be very ordinary soil, being more sandy than argillaceous, a little gravelly, and of a greyish color. It is not more than a foot in depth, and the sub-soil is a sterile calcareous sand. Water is found at the depth of two feet and a half from the surface, and it is probably owing to its vicinity, that the superior stratum of earth owes its fertility; still, no other cabbage in the vicinity rose to a greater height than three feet; and fruit trees in this same soil, flourished but indifferently. Witnesses, worthy of credit, assured us, that the leaves of this cabbage were from five to six feet in length, which were glossy, wrinkled, and resembled much those of the Cauliflower. The dimensions of Mr. Billaudeau's cabbage are as follows: The height is ten feet—it commences to ramify at eight inches above the neck. The roots are neither as large or extensive, as the immense volume of the plant seems to have required, which is the product of a seed and not of a sprout, as has been presumed by some persons. There are

thirty branches, the lowest of which are from eight to nine feet long, very divergent, curved, and lie upon the ground half of their length. At the epoch of its florescence, the principal stems of each of the twenty branches, are subdivided at their summits, into twenty flowering branches, which form in the whole about six hundred clusters of seeds. The form of the silique presents no appreciable difference, from that of the Cavalier Cabbage, but the seeds of the Billaudeau Cabbage, appeared to us less round and more unequal in size.

Now, it is a question to be solved, whether the cabbage of M. Billaudeau is a new species or a variety of a species already known. It is probable that it was derived from the Branched Cabbage of Poitou, as was the Parental Cabbage of Dauphont. It resembles the latter more than the former, as its inferior branches commence near the ground; but it differs from both, by being as high again as the Cavalier Cabbage, while the Branched Cabbage and the Parental Cabbage are smaller than the Cavalier Cabbage.

It is not probable that the Billaudeau Cabbage owes its prodigious dimensions to the nature of the soil, as it was found in the middle of a field of cabbages, all the individuals of which, except that, preserved their natural size; but it may be admitted that the seed, which produced it, was disposed to develop itself to an excess, while others are disposed to produce variegated plants, plants with curled leaves, double flowers, &c., without our being able to ascertain either why or how it has been done.

It may be asked if the seeds of the Billaudeau Cabbage will reproduce cabbages resembling the parent—for it is the chief point of inquiry. For an answer, we invoke experience and analogy and say, that even in our time, there have been formed several races, or varieties in certain families of vegetables, and especially in the cabbages: thus the Bruxelles Cabbage, has not always existed; there has not ever been several varieties of the Cauliflower. The Branched Balsom—the Dwarf Balsom—the Pyramidal Queen-Marguerite, and the Dwarf Queen-Marguerite have been created by modern culture, and form races, which are perpetuated by seeds, which are annually carefully managed in the same manner, that the races of domestic animals are preserved pure, by preventing crosses and affording them proper nourishment. The seeds of the double Dahlia produce more double Dahlias than those of the single Dahlia; the purple Capucine, which was produced under our observation, from the yellow Capucine, reproduced itself from its seed, and has been thus perpetuated, by our cultivators, by keeping them from admixture. The curled Parsley, which was not known in the time of La Quintance, and the curled garden Cress, whose origin is more recent, reproduce themselves from the seed, almost as freely as the natural species: the China Bean, a dwarf kind, from the seed of the yellow, has produced, to our knowledge, a branched variety, with white beans, which has been perpetuated by the seeds. We could cite several other plants, of a more or less recent origin, which are perpetuated by the seeds, among our cultivators, by means of a careful annual attention to them to prevent crosses; but enough has been adduced, in support of our conviction, that varieties may be identically reproduced from the seed and new races formed. Now the cabbage of M. Billaudeau being a new variety, with extraordinary dimensions, in height and diameter may, according to the course of things, reproduce itself from the

seeds, and be perpetuated by careful cultivation, and finally constitute a permanent race.

From the consideration that M. Billaudeau, by exposing his Cabbage to the curiosity of cultivators, and of all persons who are interested in the progress of agriculture, had the intention of enriching our cultivators of the earth with a new plant, whose product in leaves, for the nourishment of cattle, is greater than that of any other cabbage; and as this cultivator has shown his discernment, in the hope that this cabbage, (and it is not without example,) would reproduce itself from the seed, and become a precious plant in rural economy, your committee has the honor to propose, that M. Billaudeau be requested to continue his experiments, and make known the result to the Society, and that this report be inserted in your *Annals*.

The Society approves the present report, and adopts its conclusions.

Signed, HERICORT DE THIURY,
President.

SOULANGE BODIN, *Sec'y General*.
POITEAU, *Rapporteur*.

TREE CORN.

We never had much faith in the celebrated "China Tree Corn," that it would be of any great acquisition to the farmers of New England, and fearing it might be a "humbug," did not publish Grant Thorburn's first account of it, until we were requested to do it, after it had appeared in most of the papers of the country.

It was our intention to have no part in selling it, until we had continual calls for the article, and found, as the people would have it, it would be necessary for us to keep it. We therefore published Mr Thorburn's account, in the N. E. Farmer, vol. xvii. page 155, and procured some of the corn. As we did not have confidence in it, we added to the article published the following—"Remarks.—We have some of this corn for sale at the N. E. Farmer office, but as we know no more about it than what is contained in the above statement, every purchaser must take it on his own responsibility.—J. B."—As we supposed the quantity for sale would be very small, our first order was moderate: it was repeated for larger quantities. Erroneous accounts we think have been given to the public of the quantity sold in this city and other places.

We have seen much of this corn growing in various parts of the country, and have had accounts from many individuals since their corn was harvested, and find that ninety in a hundred give sentence against it. There are, however, some who give their testimony in favor of it—not so much on account of its being an early corn, (for such is not the fact,) but as being valuable for fodder. Dr Rowland Green, of Mansfield, has cultivated it with some care and attention, and at our request, has given us an account of it, which we give below.—We have also received a letter from Mr Thorburn, together with an article from the Journal of Commerce, which we also publish. We do not give place to these communications because we believe the corn will be profitable for New England, but that Mr Thorburn may have a chance to appear before the public with statements to balance some of the unfavorable accounts which have appeared against him and his corn.

We do not understand how it is that the corn

multiplied to such an extent after his first account of it—and should like to have him show how was that so much of it appeared in market.

The box of corn referred to in Thorburn's letter has been received, and may be examined by any who may take the trouble to call at our place of business. J. B.

MR BRECK—Dear Sir—Agreeable to your request, I send you a particular account of my success in the culture of the Chinese Corn. A frier in Newton gave me a small ear (said to be early and productive,) which on the first of May last, planted on ten rods of good land, well manured. The rows were four and a half feet apart and the hills about three feet asunder, and one, two, or three corns placed in each hill. It appeared not to vegetate so soon as my other corn, and when it was up I put round each hill, say half a pint of dry ashes. In about three weeks it appeared so slender and bad, that to avoid a total failure of a crop of some kind, I planted field beans in every hill.—As the warmth of the season increased, the corn grew, and finally to the height of 8 or 9 feet, producing many offsets or suckers, which grew to the height of 6 or 7 feet. Before the 10th of August ears began to appear on the suckers, but apprehending that they could not ripen, I cut them all off, affording much fodder. It was late in ripening, and was harvested in the beginning of October. There were two or three ears on each stalk, but only one or two ripened. The produce was six bushels of ears, and as near as I could judge, at the rate of from 45 to 50 bushels to the acre. The produce of one stalk was two large full ears, (on 8 1-2 and the other 9 1-2 inches in length,) producing 1175 well ripened corns.

The corn ripened very much from the strong wind on the 31st of July. As to the beans, they suffered much from the shade of the corn, but produced a good crop.

This corn requires a long and warm season on rich land, to be productive. From its numerous offsets and foliage, it appears to be a good kind to plant in drills, for soiling cattle, a method highly approved by those who have tried the experiment.

This corn has been improperly called the "Tree Corn," which I have, and is a great natural curiosity, but not productive.

Respectfully, your friend,

R. GREEN.

Astoria, L. I., Dec. 6th, 1839.

MESSRS BRECK & Co.—Gentlemen:—I observed in your Farmer of the 27th Nov., a favorable notice of the Chinese Tree Corn. I send you per steamboat to-day a small box containing 34 ears of said corn, of my own raising.

You will observe a marked difference in the appearance of the ears: this is one of its peculiarities. My seed was all from ears having the same appearance as one you will find in the box having the husks on it. I often found in the same hills ears having all these different appearances.

I also send by this day's mail, the *Journal of Commerce*: in it you will find a second letter from the same Mr Roberts. His experience in the corn exactly corresponds with my own. I wish you could give this letter a place in the Farmer.

This corn will yet be an important article among farmers, and it is a pity it should be strangled in its birth:—besides I have suffered a great deal of

unmerited abuse, and I think it but fair that both sides of the question should be heard. Your journal, Buel's Cultivator and the Yankee Farmer, are the only agricultural periodicals I have met with, that have shown themselves impartial. Most of them took sides against the corn, and never published an article pro contra, though they met them in many newspapers and journals, from the pens of disinterested correspondents.

Near Cleveland, Ohio, a field of the China corn was examined by a committee from the Horticultural Society of that county: their opinion was that it would yield one hundred and twenty bushels of shelled corn to the acre. It is also an early corn. I think it was on the 12th of Sept. the Society held their fair at Boston: then I sent a box of my Chinese corn, fully ripe, to the fair. We have earlier sorts to be sure, but they are generally so small in the ears as not to be worth cultivating for a crop.—And that the grains from which this corn was first cultivated on this Island were found in a box of tea, is as true as that Bonaparte crossed the Alps, though we never saw him.

Yours, sincerely,

GRANT THORBURN.

The following is the article from the Journal of Commerce, alluded to in the above letter:

From the Baltimore American Farmer of Oct. 2.

CHINA TREE CORN.

There are few subjects on which such opposite opinions have been formed and expressed, as there have been in regard to this corn. Whilst in some places it is denounced as a humbug and a cheat, in others it is declared to be a valuable and prolific variety, and is considered worthy the attention of the farmer. We have heretofore published communications highly favorable to it, from Mr Sangston and Dr Muse, and we present a second one this week from the pen of Ed. P. Roberts, Esq., who has felt it due to Mr Thorburn to give this second testimony in his favor. We frequently hear of disappointments in the result of planting seeds, which in many cases are produced no doubt from unsuitable location, or other similar circumstances, but there is little doubt are as often from the want of genuineness in the seed. As we are anxious to do justice to every one, we most cheerfully give place to the communication of Mr R.

J. S. SKINNER, Esq.—Dear Sir—In publishing my note on the subject of the Chinese Tree Corn, of the 31st of July last, you appended a note from a correspondent of Fairfax county, Virginia, who remarks, that he had "planted two ears of the Chinese Tree Corn upon land well manured and limed—the result will prove it absolutely worthless, and more like a rush than a tree."

I have read also in your paper an article from that excellent paper, "The Yankee Farmer," whose editor affirms that "the China Corn is a complete deception practised upon the credulous and confiding public," and adds with great severity—and if the Chinese Tree Corn was the worthless thing represented, with equal justice,—that the author of the deception would be entitled to the severest reprobation. The same article contains the declaration of Mr Howard, the able conductor of the Zanesville Gazette, that it was not an early corn, and that some farmers "observe that it will require two years to mature this corn."

I have no doubt that each of those gentlemen

have spoken conscientiously upon this subject, and I am equally certain, from the result of my own experiment, that they have been deceived in the variety of corn they have purchased as the Chinese Tree Corn; for it is impossible that results so different to my own, could, under any other circumstances have occurred.

As I promised you in my former note that "in the fall I would measure my little patch, and give you a faithful account of its yield," I now proceed to redeem that pledge, and I do it with the more cheerfulness, as I conceive it but an act of justice due to Mr Thorburn, that those at least with whom his corn has succeeded well, should speak of it as it deserves, in order that so far as their moral influence may go, his name may be rescued from the fate of those who practise deception either upon private individuals or the public.

With these explanatory remarks, I will state its yield, and such other characteristic traits as it strikes me to possess.

My patch was planted on a plot of ground in my garden, 32 by 23 feet in dimensions, making 736 square feet. The soil was a deep rich loam, which, as I described to you, I highly manured. It had the benefit of good culture, and its working was always done at the right time. On the 15th of September, I gathered and housed my little crop, consisting of 254 good ears, rejecting all the nubbies. While the corn was in the roasting ear state, as I observed in my former note, I pulled 24 good ears. If then I add these to those I pulled on the 15th of September, it gives the product of 268 ears on 736 square feet of ground, and as there are 43,560 sq. feet in an acre, the yield, calculating that each ear will shell half a pint of corn, was at the rate of 128 33.64 bushels per acre. But this is far short of the actual yield, as one of my cows found her way into my garden on the night of the 25th of August, and destroyed a considerable quantity. Besides this, my chickens depredated largely upon it. Having spoken of its yield, I will proceed to state its peculiar traits of character.

Its suckers branch out from the root, and after arriving at maturity, it is difficult to distinguish them from the main stalks, being so nearly equal in size, and so alike in appearance.

The stalks and suckers were from 9 to 11 feet high; not so thick as may be supposed from the number of suckers which were thrown out and permitted to grow, as the larger varieties of field corn, which are generally carefully suckered. From actual measurement, however, I can state that the suckers and stalks in my patch were from 3-10 to 4-1-10 inches in circumference, measured four inches from the ground. I planted but two grains of corn in each hill, and yet those hills had on them 10, 14, and in one instance 19 good sized ears each.

The ears have 10 rows of grain on them, are from 8 to 11 inches long, of medium thickness:—from the grain a beautiful pearly white flint, of great specific gravity, and from the sweetness of the roasting ears which we cooked, I have no doubt will prove an excellent meal corn, and be found to possess a very large quantity of saccharine matter. It makes, as may be presumed, a very large quantity of fodder; and on that account is desirable to a very great portion of corn planters, most of whom rely in a measure upon their cornfields to furnish winter provender for their stock.

So far from its being a late corn, and requiring two seasons to mature it, I consider it an early corn, which opinion is borne out by the fact of my having

gathered and housed mine on the 15th of September, a period when much other corn is scarcely out of the milky state.

I have given the result of my own experience above, and will add, that two of my friends who made experiments with it also, speak in high terms of its productiveness. Besides these gentlemen, I observe in your paper that Dr Muse and Mr Sangston, of the eastern shore of this state, are well pleased with their experiments.

I have thus discharged a duty which I owe to Mr Thorburn, and will remark, that in doing so I have no possible interest, either of a pecuniary nature, or of feeling, to subservise. He is a gentleman that I know not except by reputation. I have never had the slightest correspondence with him; and in all human probability never will. But it is sufficient for me to know that he is a distinguished seedsman, and that he is the original of Laurie Todd, to make me feel solicitous about his fame, and willing, whenever that fame may be assailed with unmerited obloquy, to take up the gauntlet, couch a lance, and run the hazards of a tourney in his defence.

I will conclude this, perhaps uninteresting letter, by stating, that I am so well pleased with the Chinese Tree Corn, that I have determined to plant no other kind next season as a crop corn.

Respectfully, your obt' serv't,

EDWARD P. ROBERTS.

Mulberry Grove, Oct. 1, 1839.

Preservation of Vegetables.—In several European countries, particularly in the north, roots of all kinds are preserved merely by secluding them entirely from air, heat and water; this is done by digging deep ditches in a dry soil upon a spot a little elevated, and depositing in them the roots, which are afterwards covered over with a layer of earth of sufficient thickness to prevent them from suffering by the frost; over the whole is then laid a bed of straw, broom or fern; in order to protect them from rain and from the water of melting snows which might filtrate through into the pit.

Roots to keep well, must have their surfaces entirely free from moisture before being thus buried.

The roots have in themselves a preserving principle, which does not exist in a dead plant or one that has terminated its period of vegetation: they have as yet lived but a portion of their vegetable life: they have not formed the seeds, which secure the continuance of their species; and to fulfil this great design of nature, they profit by every circumstance which can favor and confirm their vegetation; but when placed for a time beyond the action of air, water, and heat, their organs remain at rest till again excited by the presence of these powerful agents.

As dead bodies do not retain this animating principle, the energies of which are only suspended in roots, grains, &c. during the winter, so they suffer decomposition, though less rapidly, from the contact of air, heat, and water.

In the way of which I have just spoken, beets, carrots, potatoes, and many other vegetables may be preserved uninjured till summer.

A very simple method of preserving them, at least free from decomposition, is, to heap them up in piles upon a very dry soil, and then to cover them upon all sides with straw enough to protect them from rain and frost; in England, this is esteemed the best method of keeping turnips.—*Chaptal.*

From the Farmer's Monthly Visitor.

THE BROWSING OF SHEEP DURING THE CONTINUANCE OF SNOW.

Two of the most successful wool-growers within the knowledge of the writer are Stephen Sibley and Joseph Bernard, Esquires, living in the immediate neighborhood of each other in the adjoining town of Hopkinton. These gentlemen, from the choice flocks which they possessed, have been able to sell their wool at their own doors at high prices, when the ordinary wool could hardly be disposed of at any price. Mr Sibley has a mountain pasture, extending over the back of old Kearsage, which he has recently cleared: from ten acres of it the last season he had a fine crop of rye, which he carted fifteen miles in the straw to his own homestead.

Below is presented a letter from Mr Sibley, which we find in a Maine agricultural paper published three years ago, and in which he describes at length his method of feeding sheep on browse in the winter. We have no recollection of before having seen this letter, although we have had a similar description from the mouth of Mr Sibley. This gentleman may be relied on as a safe adviser, because he has had many years' successful practice in the rearing and keeping of sheep. His system of browsing, we believe, is continued at the present time. His letter contains valuable hints to wool-growers.

Hopkinton, N. H., Oct. 25, 1835.

My Dear Sir:—On the return of your uncle I was told you wished to know my method of browsing sheep. As soon as the ground is covered with snow I browse my sheep daily. I go to the woods and make one or more temporary cribs by placing two poles parallel 18 or 21 inches apart, upon two handfuls of brush or billets of wood. Between the poles I place or set my boughs of hemlock or hard pine—(probably spruce, fir, or cedar will do as well)—thrusting the butt ends into the snow and having them lean the same way. I extend my cribs till they well accommodate the number of sheep I wish to feed. I then tread down the snow about the cribs so that sheep can easily pass by those that have reached the browse and are feeding. I then turn my flock to the cribs, and my work is done. In the latter part of the winter, when the snow is sufficiently hard to bear up the sheep, I thrust the boughs, when cut off, into the stiff snow, in rows without poles, but so close together as to prevent the sheep passing through them.

Three winters ago when I began to browse my sheep, I cut my browse and threw it about at random; but I soon found my sheep too nice to feed in that slovenly manner. They would run over it and leave it. I took the hint of arranging in the way I have mentioned, from nature, for I have observed where boughs pendent from the trees were sufficiently low to be reached by the sheep, they would go directly to them and feed more freely than in any other way. Sheep are not pleased with having their food touched even by the hand of man.

The advantage of browsing sheep is no longer doubted here. It gives them exercise, fresh air and green food during the whole winter. I drive my sheep in flocks of from fifty to one hundred, nearly a mile every day, unless the weather is very tempestuous, and they heed cold weather as much as the deer or moose that range about the White Mountains.

A farmer in this town wintered about seventy-five sheep wholly on browse and a gill of corn a day to each. His flock were not at the barn during the winter, and they come out of the woods in the spring in fine order. He was fortunate with his lambs that season, and the following fall sold his wethers to the butcher for four dollars a head. I believe he had a slight covering to protect his sheep from storms. I give no grain of any kind to my sheep, except to my lambs the first winter, or to a few old ones that may be feeble; to these I give at the rate of a quart daily to twenty-five. To my breeding ewes I give half a gill a day for three or four weeks before they yearn. I keep my stalls dry and airy, and daily brush every straw they leave from their cribs. For the last three winters I have wintered 274, 367, and 275, and have lost but two during the three winters. My breeding ewes last winter numbered 127, of which seven proved barren. I had two lambs killed by a fox—two died by taking cold after castration—one from being trod upon when very young, and one came too feeble to live, and died—loss in all, six. I have since disposed of five, and my lambs now number 102; and a more plump, healthy, and beautiful flock I think cannot be found in New England.

I have lately sold 66 of my old sheep, and my whole flock now numbers 311. I have brought up my flock mostly from Merino ewes, and they are now from full blood Saxony to those made nearly so by breeding from the finest Saxony bucks for nine years. My fleeces averaged 2 lbs. 6 oz. and sold at 75 cents. My store sheep sell from 3 to 10 dollars a head. Yours, &c.

STEPHEN SIBLEY.

P. S.—Since the foregoing article was put in type, Mr Bernard has exhibited at our office a beautiful silver medal of the New York American Institute with this inscription on one side:

"Awarded to Bernard and Sibley, for the best American Wool, 1835."

The other side contains the arms of the State of New York, surmounted with the words *"American Insti. etc."*

It is much to the credit of Messrs Bernard and Sibley, and honorable to the Granite State, that these gentlemen should have exceeded the wool-growers of any other State in the quality of their wool; that they should give to our State the name of producing, at the extensive exhibition of the New York American Institute—which has become an Institute for the whole United States—"the best American wool."

During the year 1837, Mr Sibley disposed of about one hundred and fifty of his fine woolled sheep for exportation to Buenos Ayres in South America, some of which were sold after their arrival as high as seventy dollars each. These sheep were about 7-8 Saxony blood, crossed on fine woolled Merino: they were sold at a time of great depression in the price of sheep in June, when the prospect for wool was poor indeed. Mr S. obtained five and a half dollars for the unshorn, and four dollars each for the sheared sheep. His finest wool that year was sold at fifty cents the pound.

BENEFIT OF LIMING AND GREEN MANURE WITH PEAS.

To the Editor of the Farmer's Register.

Beaufort Co., N. C., Oct. 11, 1839.

I learn by your communication to me some time since, that it is your wish that I should let you

know my plan of liming, and also that I would communicate the same for the Register. I will cheerfully do so, but that I am a plain, and far would be a practical farmer, and have never written any thing of the kind. But, however, for the sake of being of any benefit to agriculture, if a benefit may be derived from the few hints that may advance, I will now attempt to comply as far as my feeble efforts are capable of doing.

When I took possession of my farm, I found it a very poor and worn out state, so much so that became almost discouraged, and would have engrated to some other one, had I the means to have done so without making a sacrifice; and not willing for that I came to the conclusion that I would remain where I was, and see what I could do in way of improving my poor and worn out land, which I commenced by raking and scraping all the manure I could fall in with; and coming across a treatise in some one of your volumes upon liming, I fell upon that to see what I could do with it. The first part or cut of my field that I commenced liming was of a kind of stiff and sour soil, subject to almost (I may say) every kind of insect; and it with great difficulty I could get corn to stand on. But as soon as I commenced liming I found there was a great difference in the nature of the soil as well as the quantity of the grain, which induced me to procure all the shells I could get, and put them upon my land; and I can now say that have improved my land, from liming and other manures, of which lime is the prominent part, from 50 to 50 per cent. My plan is to burn the shells just so that they will crumble.

I prefer putting them out on the land in the spring, say the last of March, upon land that I intend putting in corn; spreading the lime broadcast and about the last of June or by the first of July sow the same land in peas, which is the last work I give my corn. As soon as the corn will grow I take the fodder off. As soon as that is gone through with, I proceed to weed all down between the rows, peas and every other vegetation, which soon as done, I proceed to gather the corn and scow wheat upon the same, taking care to run a furrow each side of the ridge in the row with a single horse plough before sowing, so as to cover the ridge up as near as possible; the balance of the row I break up with the same plough. But before I sow my wheat, I soak the quantity I want for seed in strong lime water, say 24 to 36 hours; after which I strain it through a basket or colander, and as soon as that is done, I roll it in slacked lime until every grain is perfectly saturated with lime, that it parts, in which state I let it go to the ground, taking care that the seedsmen prevent the lime from injuring them. This process I think, and an certain, is a preventive from the smut, and putting on limed land I think is an obstruction against rust, or at least I have not been troubled with either since I tried the soaking and liming. The quantity of lime I generally put on my land is from 50 to 50 bushels to the acre, afterwards sowing down peas as above stated; and I can say this year that I never was more gratified; for I never saw more flourishing crop of wheat on the ground all life, (and my neighbors certified to what I now say.) for I raised 25 bushels to the one sowed; and I had the same piece of ground in wheat this year ago, and I am certain I did not raise ten more.

A FRIEND TO AGRICULTURE.

For the New England Farmer.

INDIAN CORN.

Being somewhat of an old man, and having been engaged in farming nearly all my life, I purpose, as I have time, and feel inclined, to occasionally in the course of the present winter, (in such language as my mother learned me, having not much education, the early part of my life having passed in the time of the revolutionary war, when schools were few and far between, and what there were, none of the best,) offer you some remarks on that important subject. And first on Indian Corn.

Some years ago, a writer in the New England Farmer stated, that the roots of corn had been found, several, if my recollection is right, three or four feet below the surface. This assertion, according to my observations for fifty years, is incorrect. The roots found so deep in the soil must have been the roots of some other plant, for I believe that no observing, practical farmer will admit, or believe, that the roots of corn ever penetrate below where the soil has been loosened by the plough. So far from the roots of corn penetrating deep into the soil, the reverse is the fact, and a careful examiner will find all the principal roots near the surface, hence the reason that corn is an exhausting crop.

A writer in the Yankee Farmer of the 13th of April last, over the signature of "Philo," and dated at Portland, has attacked a report of the Agricultural Committee of Massachusetts, for recommending the spreading of compost manure and harrowing it in, and has said something about "yearling farmers," and burying manure deep, and how old errors and habits adhere to people. Now I suspect that Philo is not so much as a yearling farmer—certainly not a very observing one. Philo says that perhaps he may get a better crop the first year, that is, by not ploughing the manure in: "but this is not the true theory of farming, to get one crop and exhaust the land with that." I understand that Philo means to say, that it is an old practice to spread the manure and not plough it in, but to harrow it in. The old practice was, to plough in manure, and it must be ploughed in as soon as it was spread, because it would dry and injure it—(I mean green manure.) This practice was found by experiment to be a wrong one, because covering manure so deep, when in a cold state, it did not come to that state to benefit the corn so soon as when left on or nearer the surface. If I were to plough in my green manure, I should choose to have it spread and lay at least two fair days in the sun, before ploughing: it will thus get into a state to benefit the crop much sooner than when ploughed in cold.

Within a few years much has been said, and some published, in favor of ploughing in manure, which looks too much like theory. We, or rather I, hear nothing of experiment. Now one grain of experience is worth a pound of theory. My practice has been, generally, for forty years, to spread my manure and harrow it in, and I get better crops of corn, and my next succeeding crops, are better than when the manure was ploughed in, and my land has been improving in proportion to the quantity of manure applied, and is now worth double for grass that it was fifty years ago. Many years ago, I knew a farmer who, when he was going to plough grass land, for a crop of corn, first spread his manure on the grass and turned it under the furrow, and I never knew him to raise a large crop of corn. I have known some good farmers, who

have tried spreading compost and harrowing it in, and found it much superior to any other way of applying manure for a crop of corn. The last season I ploughed a field of green sward, a part of which was ploughed in the fall—another part in the spring—it was harrowed lengthwise of the furrows, manure spread on, and then harrowed again. As experiment, and to test the new mode, the manure was spread on to about six rows before ploughing, and turned under the sod. The result was, on that ploughed in the fall, the corn was the best; that ploughed in the spring and the manure spread after ploughing, next best; and where the manure was spread on the grass and ploughed in, about half equal to the others, and also later.

You may probably hear from me again on this subject, before long. A FARMER.

Dec. 16, 1830.

MILKING.

That a material loss is sustained by the dairyman, in the manner in which the process of milking is usually performed, can scarcely be questioned by one who has paid attention to the manner in which milk is produced, and the nature of that fluid. In milk, the most valuable part is the lightest, as we see from the cream rising to the surface of the vessel: and it is reasonable to suppose that the same relative position is maintained in the udder as in the pan or pail, that is, the cream or richest part is in the highest part of the lacteal vessels, and of course is the last to be extracted in milking. When therefore, this operation is carelessly or imperfectly performed, or in other words, the cow is "milked clean," the best part is left in the udder, and lost to the dairy. It may be said, however, that what is left at one time, is obtained at the next milking, and is not, therefore, lost; but it must be remembered, that the process of absorption is constantly going on, and that by leaving the richest part for this action of the vessels it is irrecoverably lost; and besides the more completely the vessels are emptied, the greater the action will be. All dairymen are aware of the fact, that to dry a cow, nothing more is necessary than to only drain her udder at each successive milking. The secretion of the milk will cease, and the absorbents become active in proportion as the milk left incites them, until none will be left; and this result, in a greater or less degree, always ensues where the milk is not fully extracted. This also explains why a cow milked three times a day, will give more milk in the twentyfour hours, than when milked only twice.

In a large dairy, "dripping" or stripping the cows, after they have been milked in the usual manner, is practiced, and with evident profit, as the milk thus obtained is very nearly pure cream. A writer in the Farmer's Magazine thus describes the manner in which this last draining of the udder should be performed:

"The milker should be instructed to milk as fast as his strength will allow; and the idle or slow milker I would at once discard from this branch of the dairy. When he has obtained all the milk he can by the common method, he should be required to press moderately with his left hand the upper, and every part of the udder so as to force downwards all the milk that may be remaining in the smaller or higher milk carrying tubes; and as it is pressed into the receptacle and test he should milk it out with his right hand, until the whole is com-

pletely discharged. The same plan must be pursued with the remaining quarters of the udder. It must not be supposed that this method will be distressing to the animal; on the contrary, her quietness during the process, is a satisfactory indication that it occasions no pain, but rather an agreeable sensation. This plan, though effectual in keeping up the cow to her full quantity of milk, will not, generally speaking, take more additional time than a minute over the old mode of milking, and persevering in this plan, all the milk will be obtained, the richest, as well as the thinnest of course."

It is by attention to minute things, that most of the profits of the farmer are realized, and we are confident that by attention to this point, non-essential as it may at first appear, the dairyman would find that an important addition would be made to the sum total of his annual profit.—*Genesee Farmer.*

WATERING CATTLE IN WINTER.

Perhaps it would excite the surprise of many of our readers, should we assert that cattle generally suffer more from thirst in winter than during the heat of summer. Yet there is strong reason to believe that this is to a great extent the case. Cattle whose winter food consists entirely of hay, straw, and other dry materials, need a plentiful and frequent supply of pure fresh water. This many do not obtain, as nearly all running streams are covered with ice, and cattle are obliged to wander a considerable distance from the yard to the watering place, through deep snows or over a slippery path, exposed to the annoyance of dogs, or to be gored by other cattle, and rather than endure this, they often suffer much from a want of water. It has been ascertained that a bullock who has water at command, will drink it eight times a day. It should always, therefore, be of easy access to cattle at all times; and not on a distant part of the farm, or in the open road, so that in order that your cattle may help themselves to it, you are obliged to leave your gate open, or barn-yard bars down, and thus your yard is thronged with vagrant colts and other ill-bred animals, who take possession of whatever fodder they can lay their mouths upon, and pay no regard to the rights of *uero* and *tuero*. Dr Anderson says that he knew a man who became very rich by being *great in little matters*, that is, attending carefully to things which other men consider of too little consequence to claim their notice; and this man always made it a point to see that his cattle, particularly his milk cows, should have a constant supply of pure water.—*Farmers' Cabinet.*

Soiling Cattle.—Soiling is the feeding of cattle either in the barn or yard, through the summer, with new mown grass or roots. The following are some of its advantages over pasturing—1. A spot of ground which, when pastured upon will yield sufficient food for only two head, will maintain five head of cattle in one stable, if the vegetables be given in proper order.—2. The stall feeding yields at least three times the quantity of manure from the same number of cattle.—3. The cattle used to stall feeding will yield a much greater quantity of milk, and fatten faster than when they go to the field.—4. They are less subject to accident—do not suffer so much from heat, flies and insects—on the contrary, if every thing be properly managed, they will remain in a state of constant health and vigor.—*Von Thier.*

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, DECEMBER 25, 1839.

SILK CONVENTION AT WASHINGTON, D. C.

The cultivators and producers of silk, and all persons interested in the production of silk in our country, were invited by circulars from the National Silk Society, to attend a convention in Washington, the seat of government, on the 11th day of December, this current year, with a view to consult on this great subject of national interest, to collect and combine whatever practical information could be obtained in the case, and to devise means of diffusing and extending this information throughout the whole country.

The convention met accordingly in respectable numbers; and it was found on calling the roll that, besides the District of Columbia, fourteen States were represented. The convention united with the American Silk Society and proceeded with great spirit in the business of their meeting.

The American Silk Society had proffered several premiums, amounting in the whole to five hundred and fifty dollars, to be awarded to the person who should produce the largest amount of reeled silk—to the person who should produce the largest amount upon one quarter of an acre—to the person who should produce the best specimen of silk cloth—to the person who should produce the best pound of manufactured sewing silk, and some other objects; for all which claimants appeared; and when the awards are known, we shall announce them.

The specimens of raw and manufactured silk, both cloths and sewings, were of the most beautiful description; not surpassed by any ever imported into the country. They demonstrated to the perfect conviction of every observer, that it may be done, and that there is nothing in our soil, climate, natural or political condition, to prevent our producing the article in perfection, and to an amount sufficient not only to supply our own domestic wants, but to make it a prominent and profitable article of export.

On the evening of the twelfth, many valuable details drawn from actual experiment, were given; and a highly intelligent and respectable gentleman from New Jersey, the Rev. D. V. McLean, went into a full account of an experiment he himself had made the last year, with a view of ascertaining, with all the exactness that he could apply, what amount of silk could be produced upon an acre, and at what expense of time and labor. The experiment was conducted with such minute accuracy and fidelity as to leave no doubt of a similar result under similar circumstances in any other case. The result was not so extraordinary or extravagant as many persons have indulged themselves in believing that it would be; but it was sufficient to establish the great point, that no agricultural production whatever, capable of being raised in any part of the country, would yield a more ample remuneration for the labor and capital required. The cost of producing the silk, we learnt, in a reeled state, would not exceed at the current prices of labor in Freehold, N. J., about seventy miles from New York and twenty miles from the line of the railroad to Philadelphia, two dollars and twenty-five cents per lb.; and at the present prices of the raw article, six dollars per pound, it would leave a profit per acre of one hundred and eighty dollars; or at four dollars and a half per pound, a profit of one hundred and eight dollars. In this calculation of expense, however, as we understood,

are to be included only the cost of labor employed; and no charge is made for trees, expense of cocoonery, or rent of land. These every one must estimate for himself.

The amount in this case produced from one quarter of an acre was twelve pounds, making no allowance for many worms that were destroyed by falling from the shelves of the cocoonery, and for waste silk, which, it was thought, might have swelled the amount one pound, or have made it equal to fifty-two pounds per acre. It was determined by Mr McLean, and very much to his honor, to make none but the most exact statements—statements on which the public might confidently rely—not warped by conjecture nor exaggerated through vanity or selfishness. The trees used in this experiment were the *Morus Multicaulis*; and they were planted in the form of roots, cuttings, and buds, in the month of April; and the feeding of the worms and reeling of the silk occupied three hands about twelve weeks. We state these points as well as we can from recollection. The report of the experiment in full is given in the last number of the *Journal of the American Silk Society*, and will be transferred entire to our columns. We know, as well from the manner in which it is drawn up as from the important results which it discloses, that it will be perused with the highest interest, and by every friend to domestic industry, with an equal gratification.

The experiments of Mr Aaron Clapp, of Hartford, Ct. who likewise exhibited a magnificent sample of raw and manufactured silk, lead to the same results as to the cost of production. So do those of Mr Timothy Smith, of Asher, Mass., who was likewise present with as beautiful samples of raw and manufactured sewing silk, done up in the neatest manner. Mr Smith is well known among us as an experienced hand; and a successful competitor for premiums, having already had, we believe, several silk tassels and ribbons tied round his neck by the Hampshire Agricultural Society. We wish he may go on, while he is thus benefiting his fellow citizens and the country, with an equal and increased success, until he gets premiums enough to clothe him, if he chooses to wear it, in silken and flowing robes as brilliant and magnificent as those worn by the sovereign of the Celestial Empire or the Grand Seigneur of Persia. Mr Smith has stated again and again, that the bounty offered by the State of Massachusetts, amounting on silk manufactured into sewings to two dollars on every pound produced, is, according to his experience, more than sufficient to pay the cost of production.

The Society held repeated sessions until the evening of the twelfth, when a great meeting was held in the Representatives' chamber at the Capitol, where the silk productions were exhibited, and presented a spectacle which quickened most powerfully the circulations in every patriotic heart, and kindled brilliant and surprising, but we believe not delusive visions of the future, in the minds of all who feel a strong interest in the growing prosperity of the country.

The notice of the meeting was imperfect, owing to the lateness of the hour when it was ascertained the hall could be obtained; but the attendance was full. The attendance of ladies added much to the interest of the occasion; and the rustling of their dresses and the gay brilliancy of their ribbons, showed by what right they took an interest in the productions of these humble operatives, whose cast-off garments constituted some of the brightest adornments of regal pride and glory. The interest felt in the occasion was strong, and we are satisfied gathered a stronger impulse than it ever had before in the encouragement and progress of this great patriotic, and, when all its extended influences upon the humbler classes of the community to whom it will give almost

without any capital but health and hands, the means of comfortable support, are considered, we may say no only political, but moral enterprise.

After resolutions prepared by the Executive Committee were introduced, affirming the practicableness and the profit of the silk culture, and the importance of its production as a source of national wealth, it was assigned to the Rev. Mr McLean, above named, to open the discussion. He occupied the undivided attention of the meeting in a speech of about one hour and a half, of remarkable ability and power. Of this speech we shall furnish a sketch in a future number; and indulge the hope that we may presently have it *in extenso* from the author himself, in the pages of the *Silk Journal*, the Society having requested a copy. He was followed by other gentlemen, who took different views of this subject, and showed its various bearings upon morals, and domestic comfort and competence.

The meeting was then adjourned to Friday morning when it is understood the premiums will be awarded and the proposals for future competition announced.

The House of Representatives had not yet been organized. It had been in the course of the day a scene of excessive turbulence and violent and angry collisions. It was with the deepest and most painful anxiety for the honor of the country and the permanence of its free institutions, that we witnessed these excitements, approaching at times a point of explosion which threatened consequences whose limit no sagacity could foresee, and which foreboded nothing but unmingled evil. May Heaven save the country from these horrible results of party strife.—It was, therefore, doubly refreshing to retire from scenes of turbulence so unworthy and alarming to an assembly in the same hall, moving on in undisturbed harmony and good will, and with a common single purpose, to advancement of objects of domestic competence and comfort and of national wealth and prosperity. H. C.

Dec. 13, 1839.

DILLINGHAM POTATOES.

We have been favored by John Benson, Esq. with a sample of these potatoes, and can recommend them as a most excellent. They are highly farinaceous and of a agreeable flavor. He has them for sale at his store head of Market wharf, and those who are particular in their preferences in regard to a vegetable of such universal use and indispensable necessity, will not be disappointed in buying these.

It is hardly practicable to raise potatoes of the best quality in our old and highly manured soils, and subject as we are to severe droughts. Potatoes in order to be first rate in quality, require a virgin soil, a deep rich mould and a moist cool climate. These Dillingham potatoes, we believe, from Nova Scotia, or a remote part of Maine, where both the soil and the climate are favorable.

A limestone soil is likewise particularly congenial to the growth and quality of potatoes; and instances of the result are so numerous within our knowledge, we are satisfied that there are few cases in which the quality of potatoes would fail to be greatly benefited by the application of half a gill of gypsum placed on the seed in the hill at the time of planting.

Messrs Breck & Co. have likewise imported for sale, both this season and the last, potatoes from Eastport, Me. called the White Blue Noses, which in point of quality, in our opinion cannot be exceeded. If C.

[A notice of Mr Child's "Treatise on the Culture of the Beet and Manufacture of Beet Sugar," now in the press, will be given in our next.

BRIGHTON MARKET.—MONDAY, Dec. 23, 1839.

Reported for the New England Farmer.

Prices.—*Ref Cattle*.—We quote First quality, \$6 50. second quality, \$6 00 a \$6 25. Third quality, \$4 50 \$5 75.

Barrelling Cattle.—Mess \$5 50; No. 1 \$5 00.

Cotes and Calves.—We notice the following sales \$25, \$33, \$42, and \$18.

Sheep.—We did not learn the prices.

Steine.—A small lot were sold to peddle at 4 1-4; the remainder to close at 3 1-2. At retail from 4 to 6.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded northerly exposure, week ending December 22.

SPLENDID BULBOUS FLOWER ROOTS.

Just received by JOSEPH BRECK & CO. from Holland, a very large and well selected assortment of Dutch Bulbous Roots, among which are the following:—

HYACINTHS—Double white, double white with red and purple eyes, double rosy, double red, dark blue, light blue and yellow, single white, white with red and purple eye, rosy, pink, red, light and dark blue, yellow and variegated comprising 150 varieties of choice named sorts.

TULIPS—Fine late named sorts, fine double do., mixed single, mixed double, single and double Van Throll for forcing, Parrots, &c. &c.

CROWN IMPERIALS—Double red and yellow, single red and yellow, striped leaves, &c.

POLYANTHUS NARCISSES—White, yellow, white with yellow and citron cups, and citron with yellow cups.

NARCISSES—Orange Pheenix, Sulphur Pheenix, Incomparable, Van Sion, and Trutus catans, with double flowers; Trumpet major, Sulphur and Poeticus, with single.

JONQUILLS—Double and single.

RANUNCULUS—Large double red and yellow Turkey, and other varieties.

ANEMONES—Many fine mixed and named varieties.

IRIS—English, Persian, Spanish and Saxonia.

CROCUS—White, blue, purple, yellow, cloth of gold, striped, &c. in 25 sorts.

GLADIOLUS—Bizarrium commuais, with purple, red and white flowers; Cardinalis.

LILIES—Double and single white, striped leaved, and spotted; Caledonia, Bulferium, Martigon, Kampshakian, Aurantica, &c.

FEONUS—Double white Chinese, double red do., double red and double white, double purple fringed, fennel-leaved, &c.

Also—*Snow Drops*, Amargillis, Tuberoses, Ornithogalms of all sorts, Arum dracunculis, Geranium tuberosum, Allium florum, Hyacintulus monostrophus, plamosus, botrades and Belgicus of sorts; Fritillarias, Cyclamens, &c.

The above choice collection of bulbs has been selected with much care, from one of the best houses in Holland, and are offered to purchasers with great confidence, believing they will give universal satisfaction to all who will give them a fair trial. Orders left at the forwarding room, to the subscriber, No 52 North Market Street, office of the Nw England Farmer. A liberal discount will be made to dealers. October 23. JOSEPH BRECK & CO.

ROHAN POTATOES,

For sale at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at 85 per barrl. October 16. JOSEPH BRECK & CO.

WANTED.

From 5 to 10 tons of *Rota Baga*, *Mangel Wiertzol* and *Sugar Beets*. Apply at C. N. HARTSHORN, corner of Washington Street, and Pleasant Street. Boston, December 13, 1839. 21

VEGETABLE CUTTER.

Willis's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and esculent roots for fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public; they are aware that it has been long wanted and they now offer a machine that cannot fail to give satisfaction upon a fair trial. It will cut with ease from one to two bushels per minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at the Agricultural Warehouse, 51 and 52 North Market Street. December 18. JOSEPH BRECK & CO.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO. at the New England Agricultural Warehouse and Seed Store, Nos. 51 and 52 North Market Street, have for sale, Green's Patent Straw, Hay and Stalk Cutter, operating on a mechanical principle not before applied to any implement for this purpose. The most prominent effects of this application, and some of the consequent peculiarities of the machine are:—

1. So great a reduction of the quantum of power requisite to use it, that the strength of a half grown boy is sufficient to work it very efficiently.

2. With even this moderate power, it easily cuts two bushels a minute, which is full twice as fast as is hitherto done by any other machine— even when worked by horse or steam power.

3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.

4. The machine is simple in its construction, made and put together very strongly. It is therefore not so liable as the complicated machines in general use to get out of order.

BONE MANURE.

The subscriber informs his friends and the public, that after two years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone, and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and no charge for casks or carting.

Also, ground Oyster Shells. Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

NAHUM WARD.

A RARE CHANCE.

For sale. A partner wishing to withdraw from no old established Agricultural Implement and Seed Warehouse, having a good run of country custom, would be willing to dispose of his interest on liberal terms, as he is about engaged in other pursuits. To a person wishing to engage in a respectable and profitable business, having some ready capital, it is an opportunity rarely to be met with. A liberal credit will be given on most of the purchase money if properly secured. Any communications addressed "Lafayette," New York city, will be treated strictly confidential.

MISCELLANEOUS.

MR MADISON'S HOMESTEAD.

A letter in the *Madisonian* gives the following interesting account of a visit to Montpelier:—

Montpelier is situated on the west side of the Green mountains, twentyseven miles NNE. of Charlottesville, in the county of Orange, which adjoins Albemarle on the north. Within ten miles of Montpelier you reach Barboursville, the residence of the Hon. James Barbour, late Governor of Virginia. The Governor's farm comprises about 5000 acres of land, and produces 2000 bushels of wheat, 1000 bushels of corn, keeps 150 head of cattle, 300 sheep, 200 hogs, and 50 horses. There is a fine dwelling house, and numerous and commodious out buildings, besides cabins for the Governor's 200 blacks, of the most comfortable construction.

The Madison mansion is an oblong brick building of two stories, besides the basement, with a portico on the east and west, each extending the height and length of the building, and a wing of one story, and a basement at each extremity, with a turret on each. The main body of the house was built by Mr Madison's father. The wings were added by Mr M. A beautiful lawn, containing about eight acres, opens from the eastern portico, and is bordered by rows of lofty trees.

We need but look into the interior of the dwelling to observe how exactly every thing accorded with the exalted taste and intellect as well as religious character, for which Mr Madison was distinguished. You observe a great variety of busts, paintings and prints, have been chosen to decorate his abode. Among the number, you will see some old Flemish paintings, representing our Saviour's death, burial and passion, and other scenes from Scripture history. Here are busts of all the Presidents down to Jackson exclusive; and among others, Paul Jones, Emperor Alexander, Lafayette, Barlow, Gallatin, Clay, &c. In his valuable library you will find a just mixture of law, politics, history, belles lettres, poetry, science, philosophy and divinity; and among other works upon the latter subject, you will observe, justly conspicuous, the productions of Jonathan Edwards, Witherspoon, Gill, Doddridge, &c. From such sources, no doubt, he derived valuable aids to those reflections which determined those exemplary moral habits characteristic of his useful life.

Mr Madison's Reports of the Debates of the Convention that formed the Constitution, it is generally known, were purchased by Congress of Mrs Madison, for \$30,000, and the three large volumes they will compose, are expected soon to be published. The original writings of Mr Madison, now principally in unpublished manuscripts, are far more voluminous than the Debates, and many of them are his most valuable productions.

The surviving relatives of Mr Madison, now living at Montpelier, we may be permitted to say, are Mrs Madison, who, although advanced in life, retains that dignity and affability of manner, and that equableness and serenity of temper, that gave such a charm to the house of her husband, whether in public or in domestic life; Mr Paine Todd, who was private Secretary of the Commissioners of Ghent, and Miss Paine, a niece of Mr M. These form the whole of this happy and delightful family, who are seldom left to enjoy exclusive retire-

ment, even if it were desirable, and the social and hospitable character of Mrs Madison always attracting numbers of intelligent visitors, to whom her house is ever freely open.

The remains of Mr Madison lie in the adjacent family cemetery, with those of his father and his mother by his right side, and room on his left for those who may follow him. Many relatives are interred within the same enclosure, which is covered with box and ornamental trees, and the whole surrounded by a neat brick wall. The father of Mr Madison died when Mr M. first entered on his duties as Mr Jefferson's Secretary of State. The mother survived till within a few years of the death of her son. She was a remarkable woman, and resembled her son in mind and appearance.

The plantation embraces about 1800 acres of unbroken, rich and arable land, of the chocolate color. It was the patrimonial estate of Mr Madison's father, who lived and died upon it. The soil has been cultivated for nearly a century without manuring, and still it produces abundantly. Its crops have often amounted to 24 bls. of tobacco, worth \$200 per hogshead; 4000 bushels wheat; 6000 bushels of corn, besides flax, hemp, and all kinds of vegetables, and a large quantity of the choice fruits. There are about 100 head of cattle, mostly of the North Devonshire breed, and a few of the Durham. The former are thought to produce the most superior working oxen, the latter the best cows. There are, perhaps, two dozen horses, 50 hogs, 100 sheep, and quantities of poultry.

Mr Madison was not only a great statesman and a good farmer, but a tasteful horticulturist. He took great pains to procure and cultivate the richest fruits of all sorts, and the fruitry bears delicious evidence of the success. The beautiful walk through the garden of four acres, has become a bower of fruit trees, the limbs endearingly interlocking overhead. Verily, Shennstone might have envied it.

Who, therefore, has better illustrated by his life the entire compatibility of the pursuits of statesmanship and agriculture, and of the studies of politics and religion, than the Father of the American Constitution?

"Truth; not the words of a Magistrate," was his excellent motto. Let "modern democrats" and "modern whigs" profit by his example.

MYSTERIES OF THE KITCHEN.—I know that I run no small risk of being accused of Spartan barbarism when I assert that a knowledge of the *art culinaria* should form part of every young lady's education. Half a century hath hardly elapsed since the cook-shop was as regularly visited, even by the daughters of the higher class of gentry, as the music academy—and I am free to assert that the march of refinement in this instance hath been rather retrogradish and crab-like. No female can be injured, and many may be essentially benefited by the study. An officer's wife for instance, who hath accompanied her husband to the seat of war, may greatly aid to their mutual comfort in the absence of domestics. In a mercantile community, how many a man by reverse of fortune is compelled as an emigrant to seek his fortune in some new and unpeopled country, and who will assert that his wife would be the worse of being able to dress the wild fowl or venison which her husband's rifle had supplied? In the back woods of Canada, a

same pan is worth a dozen pianos and whole legion of guitars.

I do not say that you should teach a woman rope-dancing, because she may possibly elope with the manager of a circus. But I would have her educated so as to meet all the probable exigencies and vicissitudes of life.

CHARGES OF MARRIAGE.—When people talk of the expenses of a married establishment, they seem to forget the fact, that there is no house-keeper equal to a wife. She is a man's best and most faithful steward; and unless she have expensive tastes, or habits of extravagance, will make a pound go farther than five could do with a bachelor: I lately saw a case in point. A gentleman who, from mistaken motives of prudence, declines to change his condition, made lately at my request, an abstract of his household expenditure for a year, and it exceeded considerably the outlay for the same period of another friend who is married, and who in like manner furnished me with the data I required. I may add, that both parties move in a manner becoming their condition. Men are proverbially bad managers—and even admitting that their domestics are faithful, still the *motive* for economy is wanting, and without a motive, nothing effectual can be accomplished in this or in any other matter.

AFFECTION.—"I speak as I feel," returned Clifford; "were the woman I love suffering through poverty, I would beg with her, if I could not relieve her; through injustice I would defend her; from unkindness I would protect her; and if the world forsook her, I would be to her the world."

WELLES'S PREMIUM FOR APPLES.

At a meeting of the Massachusetts Horticultural Society held in August last, it was

Resolved, That a first Premium of thirty dollars be awarded on the second Saturday of January, 1840, for the best specimen of Apples, produced on or before that time from seedling trees, which shall have been brought into notice since the year 1829.

That a second Premium of twenty dollars, and a third Premium of ten dollars, be awarded at the same time for the two next best similar specimens.

That the quantity of each shall not be less than four dozen.

The Committee on Fruits are particularly requested to meet at the Rooms of the Society on Saturday, the 11th day of January next, at 10 o'clock, A. M. for the purpose of awarding the Premiums above mentioned, also for awarding the Premiums on Fruits for the year 1839.

E. M. RICHARDS, Chairman.

AGRICULTURAL.

TREATISE

The Cultivation of Sugar Beets and the Manufacture of Beet Sugar.

We have been favored with a perusal of the un-
d sheets of a treatise on "the Culture of the
t and Manufacture of Beet Sugar," by David
Child, of Northampton. That work is now in
s'and will soon be offered to the public by the
lishers, Weeks, Jordan & Co., of this city.

The author has devoted three years to observa-
s, study and experience, and now gives the re-
s in a most acceptable time, when so many are
iring for information on the subject. Mr Child
at a year and a half in the sugar factories of
nce, Belgium and Germany, and had during that
t, free intercourse with cultivators and manufac-
ers, most distinguished for science and success,
has gathered together much that is important
necessary to prosecuting the business profitably
in this country. The last year and a half has
spent in forming an experimental establish-
t, and making sugar at Northampton in this
e. No person in the country is probably so
qualified as Mr Child, to treat upon this sub-
; and we have no doubt his labors will be duly
eciated by his countrymen. He has brought
ther in a clear and concise manner, all that
s essential to enlighten the judgment and di-
ct the measures of American farmers in relation
his new and pleasant branch of rural economy.
The work is divided into three parts. The first
treats upon the culture of the beet—describing
the species and varieties; the climate most
sitions for it; soil best adapted for its cultiva-
; rotation, tillage and manure; descriptions and
wings used in cultivating the soil in France;
ing; weeding; digging; keeping; raising seed;
lucce and expense of the culture. Part second
ts upon the manufacture of beet sugar, and
ining the roots; grating, with description and
re of the instrument; pressing; defecation or fil-
trification; first filtration, evaporation or concen-
tion; second filtration; second concentration;
d filtration; boiling; filling; the curing room;
boiling molasses; revivification of animal char-
l; miscellaneous observations; the Dombase
macerating system; expenses of manufacturing;
manufacture of beet sugar at Northampton.
e third part treats of the history and prospects of
business, &c.

A work of this kind has been long sought after,
we are happy in thus announcing its speedy
pearance. The author has already manufactured
10 lbs. of fine sugar, and is well satisfied that it
l eventually prove a profitable business, and
e the import'd sugars from the market. We
e his expectations will be realised, and trust
y will. It cannot be expected, however, that
re will be no obstacles in the way, or discour-
ment or failures to new beginners: it is a busi-
s to be learnt: some of its operations are nice,
will require knowledge, practice and patience

on the part of the experimenter, before he succeeds
in producing sugar to advantage.

The following chapter on soils suitable for the
sugar beet, will show the importance of first test-
ing the soil by raising a quantity of beets, before
establishing a sugar beet factory, and ascertaining
the quantity of sugar they contain, as it will be seen
that some soils produce beets from which not a
grain of sugar can be obtained, owing to some local
peculiarity.

J. B.

"SOIL.—The best soil for the beet is a deep,
rich, sandy, alluvial soil, with an open and fair ex-
position to the sun. But any soil which will an-
swer for Indian corn, will answer for sugar beet.
There is no land except the peaty or mossy, upon
which it may not be tried with success. Strong,
clayey and loamy lands will produce the greatest
bulk of beets, if humidity does not too much pre-
dominate, but these beets will not necessarily yield
a greater quantity of sugar than a much smaller
quantity grown upon an equal extent of light and
upland soil. The beet, however, is not ungrateful
for a rich soil. Such an one is undoubtedly to be
preferred, for although the juice will not be as rich,
yet the superior quantity may be expected to more
than make up the deficiency. As a general rule, a
soil inclining to sandy is to be preferred. A clayey
sand, is better than a sandy clay, provided the sub-
soil is tolerably retentive. There is danger from
excess either of moisture or of dryness. A mod-
erate degree of moisture must be sought. The bal-
ance, if it incline either way, had better be in favor
of the dry, inasmuch as the beet does not require a
great deal of moisture except during a few weeks
of the spring, when rains are usually frequent and
abundant. After that its leaves shade the surface,
and prevent rapid exhalation, while its long tap-root
penetrates the earth and draws up fresh supplies as
from a well.

Those who cultivate the beet largely for manu-
facturing, will do well to sow extensively on both
low and upland. If the season prove either wet or
dry, one of them will yield well,—if it be neither,
both may yield well.

Calcareous soils are not unfriendly to the beet.
A considerable proportion of the beet growing re-
gion of France is of this nature; and very fine
crops of beets have been gathered from it, even
where there was only three or four inches of vege-
table earth resting on a bed of chalk. This spe-
cies of soil needs up manure quicker than others.

A gravelly soil is not very good for the beet.
The large tap-root, in penetrating the earth to get
its food, encounters stones and pebbles, which re-
tard its progress and split it into forks; then, in or-
der that nourishment may be conveyed laterally,
radicles, which are of little value, are multiplied.
Still it must be admitted that the beet may flourish
on gravelly soil; but it would be well to appropri-
ate it to forage rather than to manufacturing. The
stones, as far as practicable, should be removed.

Saline soils are to be eschewed, but they are
considered favorable for beets designed for feeding
and fattening cattle.

Soils too sandy may generally be amended with
considerable facility. For the most part they rest
upon a clayey bottom, five or six feet below the
surface. This may be taken up, pulverised and
mixed with great advantage. Clayey marls pro-
duce surprising effects on this soil, and favor in an
eminent degree the growth and saccharification of
the beet. Sandy, like calcareous soils, consume
manure too quick.

It follows that still, cold, clayey land may be
benefited by sand, but it ought to be mixed with
lime and stable manure. Calcareous marls are al-
so proper and perhaps preferable.

Calcareous soils of the heavier sort, may be ben-
efited by the application of sandy loam. The
lighter sort by clay and clayey marl. Gravelly
soils may be improved by clayey loam; peaty soils,
by draining, and by the application of coarse earth,
common sand, sea sand, chalk and calcareous marl.

In all cases it will be prudent before establish-
ing a beet sugar factory, to try the soil, by raising
a quantity of beets, and ascertaining the proportion
of sugar they contain. It has been found in several
instances after erecting large works, that not a
grain of sugar could be obtained, by reason of some
local peculiarity."

THE WEST.

Gov. Hill, editor of the Farmer's Monthly Visi-
tor, in reply to a correspondent recommending New
Englanders to emigrate to the West, has the fol-
lowing just remarks:

"The cost of a journey to Michigan, to the valley
of the Wabash, or to Wisconsin, to most New En-
gland men with a family, with the outfit necessary
for his and their subsistence until he can procure a
crop on the "cheap and fertile lands" to which he
removes, will consume means to an amount suffi-
cient to lay the foundation of his and their compe-
tence and independence in the neighborhood from
which he started. The "mere pittance" derived
from "incessant labor" in New England, will not
be found so contemptible as some apprehend, when
compared with the vast products of the West. No
one expects that crops of corn and wheat will grow
there without putting them into the earth; and it
is at least a question with us whether a greater
value from an equal amount of labor may not be
derived from cultivation of the soil in New En-
gland than from the very best soil of the West. Men
of capital there may cultivate their hundreds and
their thousands of acres with the use only of teams
of oxen and horses; but the value of the crops there,
if raised to sell, is scarcely ever greater in propor-
tion to the personal labor, than the lesser crops in
quantity produced here. The poor man without
capital can procure much more of the necessities
and comforts of life from tilling the soil or other
labor here than he can there. Such a man, if he has
credit to hire money sufficient for an outfit and to
keep soul and body together until the first crop
should be obtained in the "land of promise," would
find himself embarrassed with this additional bur-
den of debt sufficient to cripple and discourage him

for years, should he be so fortunate as to survive them: his children after him, if necessity should teach them to be industrious and enterprising, might live in that precise age of every new country that should be the most prosperous; and of course the chance would be increased that they might make themselves independent for life.

There are classes of people who, if they will venture the risque of diseases of the climate, may do well to emigrate to the West. Professional young men, lawyers, physicians, and perhaps clergymen, may stand a chance of more immediate introduction to business and of the promotion which results from success in a new and growing country than they can in an old. As there is more litigation and of course more misery in the one country than the other, so the lawyer will find most business; and as there are more fevers and agues, more sickness in such a place, so the physician will find more sure and profitable employment; and even the clergyman, if men and women could be driven to be more religious from the chance of sooner dying, would find greater inducements for his labors in the far west than he finds in this land overrunning with Christian ministers and churches.

Men with moderate farms, which cannot be advantageously subdivided, having families of some half a dozen to a dozen sons and daughters, might emigrate to advantage to the cheap and fertile lands of the West, making themselves sure before they leave, that their pitch is to be made in an eligible position and in a neighborhood where themselves and families may not pine in discontent, and sigh for the associations and enjoyments which they have left.

Men of great enterprise, who have nearly dissipated their means in grasping at too much and becoming rich in a hurry, tempered down to the anticipation of rational gains from rational means, may perhaps better repair their losses and gain property by going to the West than by tarrying in the neighborhood where it will be mortifying to take a position lower than the elevation which was their first starting point.

After all there is an objection weightier than all others, to the removal of the people of New England in mass to the West; and this is, the nearly absolute certainty that all who go there will have to encounter repeated attacks of chills and fevers and severe bilious complaints before they become acclimated. To remove at this time to Michigan or Illinois, Wisconsin or Iowa, there is at least an equal chance that the emigrant will not survive five years. Nay, old as are the settlements of Ohio, the two last persons we have seen from that State returned with the cadaverous, pale faces of apparent consumption. They came back to get their health; and we were happy to be told that although the flesh had retreated until their bodies had become mere skeletons, and the labored perspiration and the glassy eye looked very like a speedy dissolution, they only wanted the fresh mountain air and the pure granite water of rough New England to restore them to perfect health in the course of two or three months. A young gentleman from this county, who had finished a collegiate education and who had been to Ohio two years, met us the day of this present writing "cadaverous and pale." He said Ohio was a fine State, as it undoubtedly is—that it was fertile and flourishing; but he said it was not, after all, what it was represented to be; and that almost all such as went there with raised expectations were disappointed.

He had been sick nearly all the time he had been absent, and he thought himself to be so clearly acclimated, that his present intention was again to return to the West, but not to the precise spot where he had suffered, when his health should be restored after his arrival at his own paternal roof in New Hampshire! The case of a worthy physician doing a good business and having accumulated a handsome estate by practising in an extensive reach in a healthy region of the county of Merrimack, is well known to the people of this neighborhood. That physician, before he attained to middle age, sold his stand and farm, removed with his wife and family, and settled down at Peoria in Illinois, where in the course of a single year he took the lead of all others in his profession: he had here extensive business, more than he could attend to. He was called in all directions by night and by day, for every body was sick and needed medicine. But he soon took the disease himself, and others in his family were attacked; his brief career was arrested, and a few short months witnessed the committal of both husband and wife to an untimely grave.

If no other objection than the diseases which are almost sure to attack the emigrant to all new settlements of the West existed, this alone would induce all such inhabitants of New England as now enjoy tolerable competence and prosperity, to pause before they changed their position. But, as the writer we have quoted, has attributed to us the individual reason of contentment with remaining in New England, with that reason existing in his own fancy alone—a reason that we possess resources to purchase "the abundant products of the West?" from means not participated by the farmer and laborers generally—we do not hesitate here to take the broad ground that the men who have not abundance, the small farmer who is not free and independent, and the person who labors at day's works for his daily bread, have a better chance for obtaining a livelihood and the means of enjoyment, to remain where they are, than they do to remove to the West, even to the cheap and fertile alluvion bottoms of the Wabash. While we have no disposition to condemn the "bold and enterprising" who remove there, we cannot admit the sequence that all who do not go there are "timid and faint-hearted." The man who refuses a challenge to a duel may be stigmatised as timid, when it will require a greater degree of moral courage to repress than to indulge the passion for fight. So the man who encounters and overcomes all obstacles at home and advances to wealth by his own exertions in a country so unpromising as this, may claim credit for at least equal courage and enterprise with him who makes a dash at the far West, in the prospect that a rich and fertile soil will at once give him competence without the necessity for further effort or enterprise.

If five years' industry and exertion are only necessary to make a man independent in the valley of the Wabash, is the writer quite sure that an equal effort will not do as much in many parts of New England? The face of the whole country is so inviting, that like the discontented cow or ox turned into a new and abundant field, the men who occupy the soil for its products, bite a little here and there, and roam from place to place, not satisfied with the abundance before them, but looking for a greater abundance at points not yet reached. In almost all directions—in New England itself when the forest is first cut down—the ground teems with production; it yields abundantly for a few

years. This spontaneous abundance cannot always continue without compensation is made to another earth for the successive crops taken from her bosom. The great misfortune of our agriculture has been, and is likely to be, that the richness of the primitive soil leads to a course of cultivation which is sure to end in sterility. Discouragement, if not abandonment, follows this sterility; the occupant is presented with a strong inducement to leave the ground no longer productive, to occupy other ground which will yield more abundantly.

Repeated experiment has proved, that to the industrious and enterprising, the deteriorating method of cultivation is not the true policy; those grow the most who by the product and application of manures keep up the original richness of the soil. Even for present profit, more is gained in proportion to the labor, from well prepared ground, enriched by fertilising manures. There are various substances besides mere animal and vegetable manures that may enrich the soil—there are calcareous substances, partaking of the nature of lime, which merely act on the soil without imparting an internal fertility—there are kinds of earth mixed with other kinds of earth having a similar effect. The discoveries of science, the development of the constituents of different soils by analyzation, now hereafter enable every farmer to decide at once what is the best ingredient for his particular location.

A change in New England cultivation, begun several years ago in some places near the seaboard, is rapidly extending to the interior. It is found that our soil may be made to produce many times as much as it has produced; and the secret has gone abroad that those farmers make the most money from their labor who most fertilize the earth which they cultivate.

The examples of Indian corn crops upon the lands of Winnipissogee lake in New Hampshire, challenge competition with the crops even in the fertile regions of the valley of the Wabash. There is no danger that the population of New England will become too compact or too numerous. The growth of commercial and manufacturing towns will create a necessity for improved agriculture everywhere within the reach of those towns. Create a demand for the productions of the earth beyond the present supply, and there will always be found sufficient enterprise in the New England population to progress in the march of improvement. When the abundant tracks of land neglected shall be brought into use by all the improvements of which they are susceptible, no uncultivated fertile clysmum of a distant country can tear away from their homes the intelligent population who are already reaping the benefits of their own perseverance and industry.

The West is destined to flourish, as well by natural and proper emigration from the eastern States as from acquisitions of emigrants from Europe and other foreign lands: its more legitimate increase will, however, be from the reproduction of its present population. The Atlantic States, particularly the States of New England, now stand at a point presenting the strongest inducements and the greatest encouragements to that bold enterprise which deserves success because it always earns it. Our young men will find the prospect success equally auspicious here as in any other part of the world; and those only will leave from discontent who wish to make money by their wits rather than by productive industry."

USE OF BRANCHES AND LEAVES OF TREES FOR MANURING LANDS.

Translated from Le Cultivateur, by Charles H. B. Breck, for the N. E. Farmer.

The leaves of the chestnut, walnut and horse chestnut trees, and even those of the linden tree, if cut up as soon as they fall, and placed around the roots of vines or any trees, will decay in course of time, and form a manure, the strength of which will last many years. Those of the walnut and chestnut are best. With these last the burrs can also be gathered up, which increases the bulk and does not harm the quality of the manure: it will become more powerful if a little ashes, lime, or dung of birds is mixed with it. The whole should be covered with a little earth, to prevent the wind from scattering the leaves: oak leaves should not be used in this way, because it has been observed that the places where the wind had gathered a certain quantity of them, are very sterile.

I have remarked that leaves ought to be gathered immediately after their fall, otherwise the rains of frost would cause them to lose their good quality. The leaves of willows, osiers, &c., make doubtless, a good manure, since the land on which they are made fertile by them; but it is hardly possible to use them, on account of the difficulty of drying them from the water and marshes, and of drying them sufficiently. Leaves of walnut and chestnut trees can be easily obtained. The manure is much sooner formed, and easier to spread in straw manure; much of it is used in Limousin, where chestnut trees are very common.

It was customary to spread a large quantity of these leaves at the entrance of stables, and in the stalls where the cattle were kept, as well as in the stables by the sides of roads. The successive shavings and triturations form in course of time an excellent mould from this kind of gatherings; care should be taken to gather them up in heaps at the end of winter, to prevent the strength from draining or washing away. This mould is very excellent for light lands and gardens; one can almost see vegetables grow in it.

Every one knows that the chips from joiners' benches, branches of all kinds of wood, old stumps, splintered and decayed, form a very good mould. This resource can only be had in countries where stumps are very common, otherwise it costs too much.

Another kind of manure is obtained from the manure which are cut from the trees in the summer, during the abundance of leaves. The benches covered with leaves, when half withered, placed around the roots of vines or trees, the earth being removed a little for them, and covered again with the same, will produce a fine effect, which will last many years. The owners of woods ought to be eager to profit by this indication, which experience has shown to be such an advantage, and that it is always good to prune trees during the summer.

For the New England Farmer.

CUTTING OF STALKS.

Several writers have, within a few years, recommended to let corn stalks stand until harvest, and then take all together. They say the corn will yield more, and that it is not more work to harvest the crop than when the stalks are cut. The corn may be a little heavier; but suppose it is, that

advantage is more than counterbalanced by the extra labor caused by the stalks not being cut, besides a loss of valuable fodder. I have, in several instances, had a frost take a part of my corn before the stalks were cut, so as to kill the leaves, but not to injure the corn, and did not cut the stalks; and have, in every instance, found that it cost more to harvest the crop, than to cut the stalks and secure them, and then harvest the corn; that is, it is cheaper to secure them separately, than to take both at once. When stalks and corn are cut both at once they are too bulky, and it takes much more room to secure them than to take the stalks off first, and bind them in bundles.

CURING OF STALKS.—It is a favorite method with some, to bind their stalks as soon as they think they will do, and immediately secure them under cover, and hang or set them up in an airy place. So managed, they look very nice, but do cattle like them best? This is what we want. Now it is a fact I have learned from actual experiment, that housing them is not the better way, but another way is better, as any man's cattle will tell him, if he will but try it. It is this—the next day after the stalks are cut, when the leaves are not so dry as to crumble, bind them in small bundles, and then shock them, or as it is called where I live, *pike* them— which is to set eight or ten bundles or such number as appears to be suitable to make a pike of proper shape to shed rain, on their butts—draw their tops together and cap with two bundles—when they are sufficiently dried to keep, put them into some building, and if the butts are too green, place the bundles to stand with the butts upwards. In this way my cattle prefer them to any other: there is a sweetness in them that cannot be had when dried in a building.

MIXING OF CORN.—Here I shall differ from all that I have ever read, or heard spoken on this subject. The common opinion is, that the blossom on the top stalk falls on the end of the ear, and causes the mixture. This seems to me to be hardly possible, when it is considered that the silk, as it is called, lops down, as soon as it has grown beyond the length of the ears, and also that it is not probable that one blossom in a thousand, or the farina, lodges on the end of the ear. My theory, and I believe it to be the true one is, that there is a silk from the bottom, that is, next the cobb, of every kernel of corn: the silk is hollow—a tube, so to express it. Go into a field with a good glass, when this generating takes place, and I believe there will be seen a vapor, or myriads of vapors, resembling so many spiders' webs, leading in all directions, from the top stalks to the ends of the ears—I saw it once with my naked eye. This, in my poor opinion, is the way in which corn mixes,—it is by sympathy, or attraction, or whatever name the learned may call it by.

By my observation, corn seldom mixes more than two rows each way, when two kinds or colors are planted side by side—whereas if it were done by the blossom falling on the ear, I see not why it might not mix for a much greater distance, by the wind blowing the blossom. A FARMER.

Dec. 23, 1839.

Frost-bitten Potatoes.—Thomas Dallas has published some very important observations upon the modes of treating potatoes which have been affected by the frost. With us such potatoes are rejected, as being unfit either for food or for furnishing fecula. The able agriculturist above mentioned,

considers them in three different states—1st, when they are slightly touched by the frost; 2d, when the outer portion of their substance is frozen; and 3d, when they are frozen throughout.

In the first case he finds that nothing more is necessary, than to sprinkle the roots with lime to absorb the water formed under the skin, which would speedily occasion their complete decomposition. In the second instance he causes the potatoes to be pared and thrown for some hours into water slightly salted. When the potatoes are completely frozen, he finds them to yield, upon distillation, a spirituous liquor resembling the best rum, and affording much more alcohol, and that of a better quality, than can be procured from the roots before freezing.—*Chaplat.*

Preservation of Grains.—The preservation of grains has always been an object of much consideration both to governments and agriculturists, and it is a peculiarly interesting one, because bread forms so large a portion of the nourishment of Europeans, and because the scarcity and high price of it have been the cause or the pretext for popular discontents and insurrections.

It appears that the people of the most ancient times preserved their grains uninjured through several years, merely by secluding them entirely from the action of air and moisture.

The Chinese have from time immemorial preserved their grains in pits, which they call *teon*; these ditches are either hewn out in rocks, free from chinks and humidity, or what is still better, they are dug in a firm, dry soil. If there be any danger of humidity about the pits, they are lined with straw, or wood is burned in them to harden and dry the earth. The grain is not put into the pits till some months after the harvest, nor till it has been well dried in the sun; it is then covered over with mats made of the chaff of the grain or of straw, and this again by a bed of earth well beaten down that it may not be penetrated by water.

Varro, Columella, and Pliny inform us, that the ancients preserved their grain in ditches hollowed out of rocks or dug in the earth, the sides of them being lined with straw. Quintus Curtius relates that the army of Alexander experienced great privation upon the banks of the Oxus, because the inhabitants of the country preserved their corn in subterranean pits, the situation of which was known only to those who dug them.

In some warm and dry countries, it has been customary from time immemorial to preserve grain with less precaution certainly than in the granaries above described, but in situations where it could be kept for six or seven years. Prosper Alpinus relates, that not far from Cairo there was a high wall built, enclosing a spot of ground of about two miles in circumference, which was filled every six or seven years with heaps of wheat; he adds, that the abundant dews of night softened the outer portions of the grain and caused it to germinate, but that in a short time the sun dried the young shoots, which then formed a hard covering to the mass, and did not permit either air or moisture to penetrate it. In a similar manner individuals may preserve their grain upon floors in the open air, merely by covering the heaps of it with mats.—*ibid.*

Let those who despair of improvement in agriculture, compare the present with the past, and all reasons for disbelief will vanish. Nature herself is improved by man—of this the apple, peach, and potato are present witnesses.—*Genes. & Par.*

From the Journal of the English Agricultural Society

PRESENT STATE OF THE SCIENCE OF AGRICULTURE IN ENGLAND.

Though the national importance of husbandry will be at once admitted by every one, it may be well at the outset of our undertaking not to content ourselves with a general notion of that importance, but to look for a moment at some of the items which constitute its annual value.

The wheat produced in England and Wales is estimated by Mr Mac Culloch, one year with another, at 12,350,000 quarters. This single head of produce, therefore, at an average price of 50s., will amount to nearly 31 millions pounds sterling yearly. The oats and beans have been reckoned at 13,500,000 quarters, and will give another head of 17-1/2 millions sterling per annum. The grass lands, again, are supposed to yield, year by year, produce worth very nearly 60 millions sterling—(50,500,000.) The practical inference to be drawn from these large numbers is obviously this,—that, if by any improved process, it is possible to add even in a small proportion to the average acreable produce either of arable or pasture land, this increase, small as it may seem, may be in fact a very large addition to our national wealth. The average produce of wheat, for instance, is stated at 26 bushels per acre: if by a better selection of seed, we could raise this amount to 27 bushels only, (a supposition by no means unlikely, we should by this apparently small improvement, have added to the nation's annual income 475,000 quarters of wheat, worth, at 50s., about 1,200,000*l.* yearly, which would be equal to a capital of 24 millions sterling gained for ever to the country by this trifling increase in the growth of one article alone, and that in England and Wales only.

But it is not merely with regard to the total of any branch of produce that numbers afford a striking result. The value of one crop of a single article of produce on an individual farm may be large, and the loss of that crop very serious; and since in the improvement of agriculture we have to look, unfortunately, at least as much to the prevention of loss as to the increase of profit, it may be worth while on this head to take an instance from a vegetable of seemingly inferior value, the turnip.

It is well known that in the south of England, during two or three dry summers preceding the last, many farmers have lost nearly the whole of their turnip crops; and that by the drought and the ravages of their accustomed foe, the turnip fly only, independently altogether of their new enemy, the black caterpillar: after repeated sowings, a crop came up, but so late in the year, that, for want of warmth, little or no root was formed, and the crop could not be valued at more than 1*l.* an acre. In the north, on the other hand, where farm-yard manure is liberally given to this crop, and carefully applied in the ridges on which the seed is drilled in immediate contact with it, where bone dust is also purchased for the same purpose, on such highly cultivated ground there would be far less risk of failure arising from the ordinary causes mentioned above. There is many a light-land farm in the south of England, of 500 acres, on which 100 acres have not produced turnips worth more than 200*l.* or 300*l.*, while the more spirited culture actually practised in Yorkshire might have yielded 20 tons of Swedes or 30 tons of turnips from each acre. It is difficult to reduce the advantages of this superior yield to a money value. At the price for which

the former roots have sold in one neighborhood we are acquainted with, a high price it is admitted, but still one that has been paid for many years, they would have been worth 2000*l.*: so that the difference in the result of the two practices would be 1500*l.*; or, if an acre of the land be worth 1*l.* yearly, a difference of produce from one-fifth only of the farm amounting to three times the rent of the whole. Without insisting, however, upon this case, which is an extreme one, the following quotation from a recent statistical work, will be sufficient for all practical farmers: "The produce of turnips when cultivated in the broadcast manner, varies from 5 to 15 tons an acre; the latter being reckoned a very good crop. In Northumberland and Berwickshire, a good crop of white globe turnips, drilled, weighs from 25 to 30 tons, the Yellow, and the Ruta Baga, or Swedish, a few tons less."

We may consider, in another point of view, the national effect which might result from a general improvement of agriculture: that is, the additional employment that would arise from any general effort made on the part of the landowner or the tenant to improve permanently, as by drainage, for instance, the texture itself of the soil: we do not mean of waste ground, but of that which is already and has been perhaps for centuries, in course of cultivation. If a pound, only, were thus laid out on each acre, (a very moderate supposition,) we shall find that, since there are 48 millions of cultivated acres in Great Britain and Ireland, a demand for country labor amounting to 48 millions sterling would thus be created: a demand exceeding that which the railroad bills professed to create in the session before last, and far more advantageous in its effect on the laborers, inasmuch as the demand would be a gradual one, not severing them from their homes and their families. The assumed outlay, however, of a pound only, for the permanent improvement of each acre, is probably far too low; 2*l.*, 4*l.*, or even 5*l.*, would be scarcely too much. There is much wet land on which 8*l.* or perhaps 10*l.* might be laid out to advantage; but at 4*l.* only, the new progressive demand for the villager's own commodity, the work of his hands, would be about 200 millions. So large an outlay as this last must indeed, in part, be necessarily deferred for a long course of years: but in whatever degree it may arise, it has, on the other hand, the further advantage arising from the nature of the work to be done, that the demand would necessarily take place in the winter months, when labor is most difficult to be obtained, not in the summer, when the crops are in progress, and the laborer finds already sufficient employment.

It would be an inquiry of much importance to investigate in detail the manner in which this permanent improvement of the soil might be conducted in the various districts of England, but the subject is so extensive that it requires to be handled separately; or, rather, it must be a leading object of our members' future inquiries, to collect such facts and make such trials as may give a solid answer to so extensive a question. Great assistance may doubtless be derived from the knowledge which geological maps have lately afforded us as to the general outlines of the various subsoils which lie immediately under the surface of our fields, and powerfully affect, as every practical farmer knows, the produce of the upper soil through which alone the plough usually passes. These beds of sand, stone, or clay, cross England in irregular courses, from southwest to northeast: the blue lias, for in-

stance, from Charmouth in Dorsetshire, to Whit Yorkshire; and thus, by the help of a geological map, it might be known that a mode of improvement which had been well tested on a farm in Dorsetshire, would be applicable, due allowance being made for difference of climate, to another in Yorkshire. Manifest, however, as is the assistance that might long since have been derived by agriculture from geology, we know no book which has endeavored until very recently to secure that kindred for the science which is the immediate object of our society's labors. But, although it is impossible to follow this question of the permanent improvement of soils into all its details, it may not amiss to look for a moment at its more general features; bearing in mind, that we are not now seeking for positive conclusions on which we would recommend that immediate outlay should be made on a large scale by practical farmers, but are endeavoring, as is the business of societies which desire to enlarge the bounds of actual knowledge, obtain such a bird's-eye view of the field of inquiry as may show us what are the lines by which we may best hope to effect our advance into a country we desire to explore. All subsoils, then, as has been said, may be roughly divided into clays, sandstones—or rather the clayey, sandy, and stony: the two former of which, the upper soil generally partakes of their mechanical nature, that is to say, the soil resting on clay will probably be close, and on sand loose; while in all the three it will cheerfully partake more or less the subsoil's nature, that is, its substance will usually resemble, more or less, the bed on which it rests, for the plain reason, that it has partly been formed by the wearing or breaking up of that bed. Where sand predominates in the soil and subsoil, thin veins of clay: not of unusual occurrence in the latter, and where these are found they may be turned to great advantage: but to all sandy ground the Flemish have long applied a method of singular perseverance and proved success, which is shortly as follows. They dig trenches of rather more than four feet in width, and about a foot deep, over the field, at such a distance from each other that the intervals or lands between them are five times the width of the trench, from the bottom of which, sunning the soil to be ten inches deep, they have therefore dug up besides two inches of subsoil, as they proceed they fling the whole over the land on which the seed has been previously sown which they thus cover. The trench, being shifted sideways each year, and the same process renewed at the end of six years two inches of the whole subsoil will clearly have been mixed with the upper surface, and the soil deepened by that amount. The original trench is then dug perhaps two inches lower, and at the end of another six years two inches more, at least of depth, will have been gained. In this way, after four or five courses of trenching, that is to say, after twentyfour or thirty years the soil is brought to a depth of 18 or 20 inches uniform quality. Nor does the industrious Flemish fold his arms when this labor of life has been accomplished. The bed of mould into which has converted the natural ground is preserved by similar toil. On a farm called Vollaender, a little beyond Courtray, consisting of about 140 acres, 9

*In 1837 Mr John Morton had the merit of publishing a treatise on the application of geology to agriculture.

†See Flemish Husbandry, by the Rev. W. Rham, p. 7 Library of Useful Knowledge.

Rev. Mr Rham went over a field of 106 acres, the whole of which has been repeatedly trenched, by the present occupier we imagine, to the depth of two or three feet.

From the New York Observer.

DR. HUMPHREY'S THOUGHTS ON EDUCATION.

Qualifications of Teachers.

(Continued.)

I remark again, that a school teacher should be a person of the most pure and elevated moral character; without a stain and above suspicion. The thought of committing the children of twenty Christian families to the care of a profane man, of an intemperate man, or of a dishonest man, is monstrous; and I am happy to know that the moral sense of the community revolts at it. However great the moral delinquencies of some parents may be, there are few, I trust, in the land, who would be willing to employ a schoolmaster of bad character. I can remember the time, however, when dissipated men of bright parts and superior education, were more or less employed, even in New England. The teacher (more commonly a foreigner), would go from the dram-shop to the school-house, and from the school-house to the dram-shop; and many a luckless boy was paid for it with the birch and the ferule. That time I hope and trust has gone by. I will not allow myself to believe that an intemperate, or an otherwise decidedly immoral schoolmaster, could find a place any where, upon a hundred leagues of territory.

But are not some districts even now, too careless in this matter? Is the moral standard everywhere as high as it ought to be? Are the most ample credentials always required? Are not some men found in the schools, every winter, who are employed rather out of compassion for their families, or from motives of economy, than from any great confidence in their moral qualifications? Every school teacher ought to be a pattern of " whatsoever things are pure, lovely, and of good report," as well as able in every branch of instruction. Nor is it sufficient that a master keep himself within the rules of propriety, during the continuance of his school. If he is chargeable with any plain violation of the decalogue, with any looseness of morality while he is engaged in other pursuits, he is thereby disqualified for the responsible duties of a public teacher. If it is known that he sometimes uses profane language, or that he does not strictly regard the Sabbath, whether at home or abroad; or that he is ever in the slightest degree disguised with strong drink—any such delinquency is a disqualification for the office of instructor. Children are quite too strongly inclined, at the best, to stray in forbidden paths, and they need all the force of precept and example, both in the family and in the school, to keep them "in the way they should go." How mischievous, then, how ruinous must be the influence of a popular school-master, who carries about with him the slightest blemish in his moral character. I shall only add,

In the last place, that *sincere vital piety* is an exceedingly desirable qualification in a school-teacher. There is nothing like the fear and love of God shed abroad in the heart, to make a man faithful in any profession, employment or undertaking.

As Moses said, when the spirit of prophecy was given to the seventy elders in the wilderness, "would that all the Lord's people were prophets, and that the Lord would put his spirit upon them!"; so I cannot help exclaiming, in this place, would that all the teachers of our schools were themselves taught of God, and that "the Lord would put his spirit upon them." Parents need all the assistance they can get, in bringing up their children in the nurture and admonition of the Lord, and there is no calculating the amount of influence which a truly pious schoolmaster or mistress may exert, over the hearts and consciences of fifty immortal beings, during the most plastic period of their existence. A sincerely religious teacher will make it a prominent object, to lead his scholars in the paths of righteousness, as well as to imbue their minds with the rudiments of useful knowledge; and it admits not of a doubt that the seeds of piety sown in the humble school-house, have taken root and sprung up in the hearts of thousands, putting forth "first the blade, then the ear, and after that the full corn in the ear."

I am quite aware, that piety in the absence of other qualifications, cannot make a good school-teacher any more than it can make a good civil ruler, a good preacher, or a good physician. And it is certain, that some men of sound Christian principles and high moral standing, though not members of the church, are upon the whole far better teachers than some others, whose piety is unquestioned and unquestionable. I do not say, therefore, that none but professors of religion should be employed. The number of such who are otherwise competent, is very inadequate, at least in some parts of the country; and we are bound to be thankful for the best talents and qualifications we can command. Still, other things being equal, vital piety is a crowning excellence in the character of a teacher; and I hold it to be the bounden duty of Christian parents to inquire for such teachers; and to give them the preference when they can be had. This may appear to some quite too puritanical for the present liberal and enlightened age; but I feel confident that a still better age will ratify the judgment; and that no parent in the light of eternity, will ever find reason to regret that he was too anxious or particular, about the moral and Christian character of those to whom he confided the education of his children.

THE LIFE OF THE HUSBANDMAN.

"I am a true laborer. I can earn that I eat, get what I wear, owe no man hate, envy no man's happiness—glad of other men's good—content with my lot; and the greatest of my pride is to see my ewes graze and my lambs suck."—SHAKESPEARE.

We have come to the conclusion that Nature's truest nobleman is the man who earns his bread by the sweat of his face, upon his own bought and paid for plantation. An independent farmer may stand upon his own house-top and say to himself, as Selkirk did—

"I am monarch of all I survey,
My right there is none to dispute;
From the centre all round to the sea,
I am lord of the fowl and the brute."

He is truly a rich monarch—with a landed title more secure than that of feudal lord or baron—more easily preserved and protected, not by deeds of valor, and through the shedding of blood, but by the lawful labor of the hands. His house is his castle; his acres his dominions. His gardens are his parks,

his grass plats his lawns, and his forests his groves. His cattle, sheep, and poultry are his subjects, and he battles, as pleasure, either the executioner or the multiplier of such subjects. Tell us if the king upon his throne has more power worth possessing. His happiness we know is less, as he increases toils, cares, and his sorrows in proportion as the cultivator of the soil diminishes his.

In the spring time he sows, in the autumn he reaps. Providence has assured him that spring time shall not fail, and he has the assurance of the Giver of every good and perfect gift, that as he sows, so shall he reap. His grounds are watered in the season of drought with the rains and dews of heaven, and in the damp season the sun shines to cheer, invigorate, and give promise to his labors. The severer tasks of the summer are succeeded by the lighter labors of the winter. As we have said, in the words of Will Shakspeare, "he earns that he eats, and gets what he wears." He may say truly, and with an honest pride—

"I eat my own lamb,
My chickens and henn,
I shear my own fleece and I wear it."

What could a man want more? and how can a farmer, capable of enjoying life, possessed of his farm-house, his farm, and his necessary implements of husbandry, ever sigh for a residence within the enclosure of a city—choosing bricks and mortar for the elbow room of a spacious farm-house,—the dust of the town for a village; the three-story brick house for the granary or the haycock; for the purest air of heaven, the atmosphere of a thousand unwholesome smoky houses, and ten thousand unwholesome breaths? How could a farmer make such a choice as this? We would pause for a reply, did we not know that the only answer which could be devised, after a long study, would be the unsatisfactory one that something better was anticipated only: for it would be a miracle, almost, for a man to find himself happier or in better circumstances after a change of residence from the country to the city. No, no. The true elysium; the real paradise on earth, is the country—the green, fruitful, beautiful country. The city for the task-master and his hard-working servant; but the country for the man who wishes for health and leisure, contentment and a long life.

The ancient Romans venerated the plough, and at the earliest, purest time of the Republic, the greatest praise which could be given to an illustrative character, was a judicious and industrious husbandman.—*Portland Advt.*

HINTS.—Do not say when you put a crop on a piece of land not adapted to it, or but imperfectly prepared, that circumstances rendered it necessary. Napoleon believed that calculating forethought and an energetic will, created the circumstances for the man, not the man for the circumstances. The man has little pretention to the character of a farmer, whose plans for the culture of his several fields are not made at least two years in advance.

Those men are always found to complain the most of hard times and high prices, who add the least to the productive resources of the country.—The farmer, who by his labor creates value from the earth, rarely complains, and need never, if he diligently follows the plough. Let those who complain, remember there is an infallible cure for hard times—honest industry applied to the cultivation of the earth.—*Genesee Far.*

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JANUARY 1, 1840.

We give below the opinion of Judge C—, in a case recently submitted. As it is the first judicial decision which he has ever delivered from the bench, and as he has been obliged to be his own reporter, he hopes any legal inaccuracy will be pardoned. We hope the principles of law will be found true and sound.

DECISION IN A CONTESTED CASE.

—, Nov. 18th, 1839.

DEAR SIR—As the season of the year has now arrived in which the cultivators of the wheat crop throughout our commonwealth are engaged in making out their certificates for the bounty on the same, I am desirous that a better understanding should be had, not only for myself but for the benefit of others who may be engaged in the cultivation of the crop, with regard to the true intent of the law in certain cases (which not infrequently occur,) between the person who cultivates the crop and the owner of the land. I will state a case in which I am one of the parties:—Late in the fall of 1837, having received a quantity of Italian wheat from a friend in the State of New York, which at that time had not been cultivated amongst us, I was induced to apply to a neighbor of mine for a piece of ground, for which I agreed to pay three-fifths of what I could raise, as a compensation for the use of the land. I accordingly ploughed my ground the same fall, (being of a rich loam soil,) and on the 13th of April following (against the advice and opinion of the owner of the land upon early sowing,) I prepared my seed, by soaking it twelve hours in brine, preparatory to sowing it in line, and sowed it one and a half bushel per acre, immediately after which the ground froze sufficiently hard to bear up an ox. At the season of the year when the heads began to appear, lime was sown on broadcast, at the rate of one bushel per acre, to prevent the work of the weevil. I harvested the wheat when ripe (three acres) which produced about 23 bushels per acre: three-fifths of it I paid over to the owner of the land, as agreed on: I then made out my certificate for the *whole crop*, (70 bushels,) stating the manner of procedure in the management of the land, &c., agreeably to the requirements of the law in such cases, making oath to the same, and presented it the same to the Treasurer for allowance. Immediately after, the owner of the land made out a second certificate for three-fifths of the crop; made oath to the same and presented it to the Treasurer, and demanded a bounty, (as I had not at that time received my bounty, it not being convenient,) the Treasurer actually paid to the land-holder a bounty on the three-fifths (or 42 bushels,) of two dollars on the first 15 bushels, and five cents for every additional bushel; accordingly when I called for my bounty on the whole crop, the Treasurer refused to pay me bounty for more than two-fifths or 28 bushels, two dollars for the first 15 bushels and five cents for every additional bushel, making a second bounty of two dollars in one case. Now it appears to me, that either myself for the commonwealth or both, have been wronged. As lands are frequently let in this manner, I am induced to address you on this subject, and most respectfully to ask your opinion as to the true intention of the law in such cases, and have the goodness to publish the same in the New England Farmer. Please send me a copy, and you will confer a favor.

Most respectfully, yours, &c.

REV. HENRY COLMAN.

The foregoing letter has been sometime, in company with others, waiting our return to winter quarters; and our absence must be the apology for apparent neglect. With the writer of the letter, whose name and residence we have left blank, we are acquainted, and believe him incapable of making knowingly any false statement.—Who the other party is, we do not know, even by name. To us, however, if the above is a full statement of the case, the matter is as clear as the light of day.

Contracts are to be interpreted according to the circumstances and conditions under which they are made. It is understood in this case that, at the time of making the contract, no reference was made to the bounty which might be obtained from the State upon the crop. The law indeed was not in existence at that time.—There was no agreement between the parties that the owner of the land should receive any part of the bounty if any bounty should be obtained; nor on the other hand that he should furnish any part of the seed, or perform any part of the labor of cultivation or harvesting; or bear any part of the expense or loss in case of a failure of the crop. The simple condition was that the lessee should pay to the owner of the land three-fifths of the crop grown upon the land that season. It was understood of course that the land was to be cultivated; and it was naturally intimated that the interests of the lessee would induce him to cultivate the land with the most profitable crop and in the best manner. Indeed, as the land was leased upon the presumption and understanding that it would be cultivated, had the lessee after hiring the land, neglected to cultivate it, we should have considered that the owner of the land had a just claim upon him to the full amount of what might be considered the fair rent of such land. But in a case, as in this, where the land was cultivated, and cultivated as it was expected by the parties it would be cultivated, both as to the kind of crop raised and the manner of growing it, the owner of the land has a claim only for that which was stipulated as the rent, and for nothing more; that is for three-fifths of what was grown upon that land that season, and this payable in kind. How this should be paid, whether in the sheaf or threshed and cleaned, must depend altogether upon agreement at the time; or upon usage in such cases, if no agreement were made. So too in regard to the straw, as the agreement was that the owner should have three-fifths of *what was raised on the land*, three-fifths of the straw belong to the owner, unless general usage establishes a contrary rule, or some express stipulation was made on the subject at the time of contracting. We suppose, however, that in this case the operation on the part of the lessee was not considered as completed until the crop was actually prepared for use or market; in which case the contract would be fulfilled on the part of the lessee by the delivery of three-fifths of the cleaned grain. If, again, in the progress of the operation it should appear that the lessee wilfully or negligently failed to cultivate the whole ground; or used seed which he knew to be imperfect &c. bad; or, through neglect, allowed his crops to be exposed to the depredations of cattle or vermin; or if a wheat or rye crop were grown, the lessee without the consent of the owner cut any portion of the standing crop while in a green state for fodder, or for bonnet straw, in all these respects the owner of the land would have a just claim upon the lessee for such damages as he might fairly prove he had sustained by such neglect or unexpected appropriation of the proceeds of the land.

The question of the right of the owner to any portion of the bounty of the State awarded upon the crop, involves in our opinion, after the views above given, no difficulty whatever. If the agreement had been that the

owner should be entitled to three-fifths of "*what could be made*" in the course of the season from the land, there would have been a fair claim on the part of the owner to three-fifths of the bounty of the State. But it was not so. The lessee agreed to pay to the owner of the land as rent three-fifths of *what he should raise* upon it. This of course was in kind, unless an agreement was made to the contrary at the time of contracting, which is not pretended. Seventy bushels of wheat it seems were produced on the three acres of land. The owner therefore, was entitled to forty-two bushels of the wheat raised and to nothing more, with the exception of conditions in respect to the straw above referred to.

The law authorising a bounty upon wheat expressly states that this bounty shall be paid to the "person who raises or causes to be raised" wheat to a certain amount therein specified. Now with what propriety can it be said that the owner of the land in this case either *raised or caused to be raised* a crop of wheat when he did nothing towards the cultivation of the crop; nor as appears if all the facts in the case are given in the letter, so much as determined what kind of crop should be cultivated on the leased land. For a man, therefore, under these circumstances to go before a magistrate and make oath with a view to obtaining the bounty, that he either *raised or caused to be raised*, is as clear a case of false swearing as ever appears in our courts. The terms of the certificate given under oath are "I have raised," &c. The oath in this case may have been taken without a proper regard to the nature of the case; but this does not alter its character.

Again, the object of the law was to encourage the cultivation of wheat in the State; to ascertain the capacities of the soil for its production; and by a careful observation of its growth and progress, to determine the best mode of cultivating this valuable crop. For when then was this bounty designed but for the actual cultivator of the crop? under whose particular direction, skill intelligence and care, the cultivation was undertaken and carried on, and to no one else. Certainly not to the owner of a tract of land, who merely leases it for a fixed rent without even stipulating what crop should be cultivated upon it.

The bounty proffered is altogether accidental and extraneous, and in the absence of all stipulation in respect to it at the time of making the contract, the owner has no claims upon it whatever, but it belongs to the cultivator.

Suppose the owner of a ship should charter his vessel to an enterprising individual for a year, upon a stipulation that three-fifths of any cargo she should bring home should belong to the owner, to be paid as charter money. The government with a view of encouraging enterprise and ascertaining whether a productive trade can be carried on with China, engage to give a bounty of fifty cents upon every pound of silk brought from Canton into the country. If the person who charters the ship brings home fifty thousand pounds of silk, then he must pay the owner thirty thousand pounds of silk. But the owner of the ship has no claims upon the bounty of the government, which was a bounty not for owning or building or freighting ships, but upon the enterprise and labor of bringing silk from China into this country. With this certainly the owner of the ship had nothing to do, since he did not even so much as stipulate that silk should be brought instead of tea or China ware. But let us suppose that instead of granting a bounty upon silk the government, after the voyage had been undertaken, thought best to lay a duty upon silk of fifty to eighty per cent., or so heavy as to make the voyage a losing concern to the shipper or freighter. In such a case would the owner of the vessel expect to pay the government

duty on his three-fifths of the silk, which he was promised for the hire of his ship. Certainly not; any more than that a creditor would be willing to receive the payment of a debt in the depreciated currency of a broken bank.

To us indeed the case is plain that the owner of the land in this instance has no just claim whatever for any portion of the State bounty—

Let judgment be entered for the defendant. H. C.

THE RHODE ISLAND MEDICINE:

AN INFALLIBLE CURE FOR HARD TIMES AND TROUBLED CONSCIENCES!

We are not in the habit of advertising either quack or patent medicines in the Farmer; but there is no quackery in the subjoined nostrum; and we hope the Rhode Island Society will not think of rendering it exclusive by taking out a patent. Under the billious complaints which are prevalent among most classes at the close of the year, we frequently recommend the Rhode Island Society's remedy as effectual. We recommend it to our customers in particular, as a certain cure for those disagreeable qualms of conscience, which we know some few of them must feel about this time; and for whose sufferings we feel an unfeigned compassion.

"We hereby acknowledge the receipt of one hundred and fifty dollars from the Rhode Island Society for the Encouragement of Domestic Industry, to pay in advance for the New England Farmer, to be distributed among the members of the Society.

JOSEPH BRECK & CO."

ERRATUM.—In Gen. Dearborn's letter on the first page of our last number, first line of second paragraph, for "fine seeds" read five seeds.

BRIGHTON MARKET.—MONDAY, Dec. 30, 1829.

Reported for the New England Farmer.

At Market 630 Beef Cattle, 50 Stores, 1200 Sheep, and 420 Swine.

PRICES.—Beef Cattle.—Last week's prices for a like quality were generally sustained. No choice Cattle were at market, consequently our quotations for first quality are reduced. First quality, \$6 25. Second quality, \$6 00. Third quality, \$4 50 a \$5 75.

Barrelling Cattle.—Mess \$5 50; No. 1 \$5 00.

Stores.—Very few sales were effected.

Cows and Calves.—Sales \$30, \$35, \$42, and \$16.

Sheep.—Lots were sold at \$1 50, \$2 25, \$2 75, \$3 25, \$3 75, and \$4 50.

Swine.—No lots were sold. A considerable number were retained from 4 1-2 to 6.

Statement of Brighton Market for 1829.

23,263 Beef Cattle, sales estimated at, \$1,116,621
 9,573 Stores, 427,056
 104,640 Sheep, 214,650
 26,088 Swine, 143,534

1838. \$1,901,864

25,830 Beef Cattle, }
 9,573 Stores, } Sales estimated at, \$2,058,004

VEGETABLE CUTTER.

Willis's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and esculent roots for fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public; they are aware that it has been long wanted and they now offer a machine that cannot fail to give satisfaction upon a first trial. It will cut with ease from one to two bushels per minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at the Agricultural Warehouse, 51 and 52 North Market Street, December 13. JOSEPH BRECK & CO.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO. at the New England Agricultural Warehouse and Seed Store, Nos. 51 and 52 North Market Street, have for sale, Green's Patent Straw, Hay and Stalk Cutter, operating on a mechanical principle not before applied to any implement for this purpose. The most prominent effects of this application, and some of the consequent peculiarities of the machine are:

1. So great a reduction of the quantum of power requisite to use it, that the strength of a half grown boy is sufficient to work it very efficiently.
2. With even this moderate power, it easily cuts two bushels a minute, which is fast twice as fast as has been claimed by any other machine even when worked by horse or steam power.
3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.
4. The machine is simple in its construction, made and put together very strongly. It is therefore not so liable as the complicated machines in general use to get out of order.

BONE MANURE.

The subscriber informs his friends and the public, that after to years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure

He keeps constantly on hand a supply of Ground Bone, and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and no charge for casks or carting.

Also, ground Oyster Shells.

Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

NAHUM WARD.

WELLES'S PREMIUM FOR APPLES.

At a meeting of the Massachusetts Horticultural Society, held in August last, it was
 Resolved, That a first Premium of thirty dollars be awarded on the second Saturday of January, 1840, for the best specimen of Apples, produced on or before that time from seedling trees, which shall have been brought into notice since the year 1829.

That a second Premium of twenty dollars, and a third Premium of ten dollars, be awarded at the same time for the two next best similar specimens.

That the quantity of each shall not be less than four dozen.

The Committee on Fruits are particularly requested to meet at the Rooms of the Society on Saturday, the 11th day of January next, at 10 o'clock, A. M., for the purpose of awarding the Premiums above mentioned, also for awarding the Premiums on Fruits for the year 1839.

E. M. RICHARDS, Chairman.

ROMAN POTATOES.

For sale at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at \$3 per barrel. October 16. JOSEPH BRECK & CO.

DOMESTICATED WILD GESE.

A few pair for sale. Inquire at this office. November 6.

THE FARMER'S CHOICE.

"A little house well filled,
A little wife well wiled,
A little land well tilled."

Our ancestors were fed on bread and broth,
And wo'd their healthy wives in home-spun cloth,
Our mothers, nurtur'd at the nodding reel,
Gave all their daughters lessons on the wheel.
Though spinning did not much reduce the waist,
It made the food much sweeter to the taste.
They pled with honest zeal the mop and broom,
And drove the shuttle through the noisy loom.
They never once complain'd as we do now,
"We have no girl to cook and milk the cow."
Each mother taught her red-cheek'd son and daughter
To bake, to brew, and draw a pail of water.
No damsel skunn'd the wash-tub, broom, or pail,
To keep unsoid'd a long grown finger nail.
They sought no gaudy dress, no wasp-like form,
But ate to live, and work'd to keep them warm.
No idle youth, no light-faced, mincing fair,
Became a living corpse for want of air;
No fidgets, faintings, fits or frightful blues;
No painful corns from wearing Chinese shoes

A HOUSEWIFE.

ARNOLD'S ESCAPE.

A correspondent of the Farmer's Monthly Visitor gives the following particulars respecting the escape of the infamous traitor Arnold, which we do not recollect of having before seen:—

Mr Ebenezer Chase was a private in the New Hampshire militia, which relieved the Pennsylvania line at West Point in 1780, when these troops, being veteran, were wanted elsewhere. Mr C. with several others, being off duty, was on the shore of the Hudson when Arnold deserted. When Gen. Washington assigned him the command of West Point, he left his own barge in his possession. A temporary hut was erected on the east shore for the accommodation of the four oarsmen who managed the barge. On the morning of his desertion, Gen. Arnold rode down to the shore, from his head quarters at Robinson's farm, very fast, as was his custom—drew the reins to his attendant, and ordered the barge to be manned. He then directed his course towards the Point; but on reaching the middle of the river, the boat was observed to take a course down stream, and move very swiftly through the water.

The explanation was afterwards made by the boatmen. He hoisted a flag of truce, and told them to pull for the Vulture sloop of war, which lay below, saying that he had some business with her captain, and promised if they would row him down to her as soon as possible, to give them a guinea and a gallon of rum each. On nearing the Vulture, and being within range of her guns, Arnold opened his plan, saying, "I have served the ungrateful scoundrels long enough," and declared if they would go with him they should have double pay, and be made sergeants in the British service. One of the men replied that "he did not understand fighting on both sides." "Then," said the General, "you are prisoners."

When they came along side the sloop of war,

Arnold ascended the deck, and was received by the marines with presented arms. He then ordered his men to come on board as prisoners of war. One of them who had been their spokesman just before, said "It was a shabby trick, as they had tolled to their utmost strength to get the boat along, now to refuse the promised reward, and make them prisoners to boot." The English captain heard their murmurs, and stepping forward, observed—"Gen. Arnold, I command this ship, and while I walk the quarter deck, no such transaction shall take place. I know the meaning of my words, sir, and will meet their comment." Then addressing the men, he continued—"My good fellows, I respect your principles and fidelity to your country, although you are enemies to your King. You shall have liberty to go or stay as you please.—Here," taking them from his purse, "are your guineas: steward put up four gallons of rum for these men." The boatmen thanked the gallant and generous sailor, and returned in safety to head quarters to report their proceedings to Gen. Washington, who had just arrived in camp. Arnold, chagrined and enraged, retired without uttering a word, to the cabin of the sloop of war.

This statement was made by Mr Chase about a fortnight before his death, in 1831.

Arnold, before his escape, had received information that "John Anderson," the name with which he had filled Andre's pass, was taken. The information was sent him by the unfortunate person himself. This determined his purpose for sudden flight. He was afterwards distinguished for the inveteracy with which he carried on his predatory warfare against the property of his fellow countrymen. After the war he went to England, where, although he received the countenance of the British government, his *good intentions* in his unsuccessful plot against the liberty of his country were despised by the British officers. The unfeeling wretch called upon the widowed mother and sister of his unfortunate victim (Andre). The servant announced to them the name of Gen. Arnold; and they immediately returned a message that they did not desire to see him. V.

AFFECTION FOR A MOTHER.—Round the idea of one's mother the mind of a man clings with a fond affection. It is the first deep thought stamped upon our infant heart when yet soft and capable of receiving the most profound impressions, and all the after feelings of the world are more or less light in comparison. I do not know that even in our old age we do not look back to that feeling as the sweetest we have through life. Our passions and our willfulness may lead us far from the object of our filial love; we learn to pain her heart, to oppose her wishes, to violate her commands; we may become wild, headstrong, and angry at her counsels or opposition; but when death has stilled her monitory voice, and nothing but calm memory remains to recapitulate her virtues and good deeds, affection, like a flower beaten to the ground by a past storm, raises up her head and smiles among her tears:—Round the idea, as we have said, the mind clings with fond affection; and even when the earlier period of our loss forces memory to be silent, fancy takes the place of remembrance, and twines the image of our dead parent, with a garland of graces, and beauties, and virtues, which we doubt not she possesses.

A gentleman expatiated on the justice and propriety of an hereditary nobility. "Is it not right," said he, "in order to hand down to posterity the virtues of those who have been eminent for their services to the country, that their posterity should enjoy the honors conferred on them as a reward for such services?" "By the same rule," said a lady, "if a man is hanged for his misdeeds, all his posterity should be hanged too!"

HOUSEHOLD SERVICE OF A DOG.—"I say, stranger," said a cottage urchin to a Yankee pedlar,—"don't you whistle that ere dog away." "Why, he aint no use no how, he's so ugly." "Oh, but he saves heaps of work." "How?" "Why, he always licks the plates and dishes so clean, that they never want washing; and mammy says she wouldn't part with him no how, for our new dog aint got used to mostard yet."

THE REPORT COURTEOUS.—As a waiter was one day igniting a huge pile of pitch pine, in the capacious fire place of the village inn, a gentleman remarked to him—"Jerry, they say that *fools* make the best fire!" Jerry, with the purest arch respect, turned round to him, and said,—“Will you take the tongs, Sir?”

AMERICA AND RUSSIA.—M. De Tocqueville, in his "Democracy in America," speaks of the destiny of the East and the West in the following manner:

"There are, at the present time, two great nations in the world, which seem to tend towards the same end, although they started from different points. I allude to the Russians and Americans. Both of them have grown up unnoticed; and while the attention of mankind was directed elsewhere, they have suddenly assumed a most prominent place among the nations; and the world learned their existence at almost the same time.

All other nations seem to have nearly reached their natural limits, and only to be charged with the maintenance of their power; but these are still in the act of growth; all the others are stopped, or continue to advance with extreme difficulty; these are proceeding with ease and with celerity along a path to which the human eye can assign no terminus. The American struggles against the natural obstacles which oppose him,—the adversaries of the Russian are men;—the former combats the wilderness and savage life—the latter, civilization with all its weapons and its arts; the conquests of the one are, therefore, gained by the ploughshare; those of the other by the sword. The anglo-American relies upon personal interest to accomplish his ends, and gives free scope to the unguided exertions and common sense of the citizens; the Russian centres all the authority of society in a single arm:—the principal instrument of the former is freedom—of the latter, servitude. Their starting point is different, and their courses are not the same; yet each of them seems to be marked out by the will of Heaven to sway the destinies of half the globe."

AGRICULTURAL.

From the Journal of the English Agricultural Society.

PRESENT STATE OF THE SCIENCE OF AGRICULTURE IN ENGLAND.

(Continued.)

A deep soil, indeed, has this double advantage or a shallow one, even though both be equally dry—that during dry weather, roots can descend deeper in search of moisture, and that moisture rises from below, by capillary attraction, more freely towards them. But where veins of clay are found interlarding, as it were, the sand, the advantage will be far greater, because the sandy soil will be brought now into that moderately adhesive state which will entitle it to be ranked as a loam. Indeed, where clay is not found on the very spot, it may often be brought, as has long been the practice in Dorsetshire and in Norfolk, by horse-labor, to a moderate distance. It is worth remark that, another part of this country, and on a different description of light soil, strong as is the disinclination of British husbandry for the use of the spade, great improvements have for a long time, over an extensive district, been effected by lifting clay from low and laying it upon the surface. It is the district of Lincolnshire to which we allude. Here the soil consists of light vegetable matter, of decayed fibres of plants, clothed in its natural state with rushes or heath. A handful of it presents very much the appearance of rappee snuff: a depth varying from one to many feet, lies a very stiff blue clay of the consistence of soap.—When the land is brought into cultivation, trenches are opened down to this clay, and a heavy dressing of it is laid on the face of the ground, which five years afterwards is found to be imperfectly mixed in small lumps with the peat. At the end, however, of twelve years, after three such doses of peat have been given, a specimen which we have seen from this same ground, instead of a brown woody substance like rotten bark, presents the appearance of a dark grey, rather stiff loam, not dissimilar to the garden mould which is usually met with round London, capable of bearing heavy crops of coleworts and wheat in rotation, being, in fact, a soil of a most valuable description of farm-land, which has been manufactured from the two sterile materials, pure peat and mere clay.

It might be supposed that the reverse of this process would also succeed, and that, as sands and clays are made firmer by the admixture of clay, heavy soils might be rendered more porous if sand were carted upon them. It has been, indeed, so attempted, and the attempt has been made, but no instance is known in which it has been found to succeed. The expense of laying on the large quantity of sand that would be required, must probably more than swallow up any profit that could be derived; and although cold lands with retentive subsoils have, in many districts, been much improved by covered drains, more or less effectively made, the hope of bringing them to a thoroughly free-

working genial temper, had been, until lately, almost abandoned. Mr Smith, however, a manufacturer of Deanton, near Stirling, some years since applied his mind to this subject; and, as the practical farmer who has this year won the first medal of the Society, states Mr Smith's process to be the greatest improvement effected in agriculture since the introduction of turnip culture, (that is, for the last century,) it is impossible to pass it over, although, of course, its introduction is too new to be placed already altogether beyond the risk of disappointment. Mr Smith's mode of dealing with a clayey subsoil, which holds up in the soil the water that has fallen in rain, and thus exerts some unexplained evil influence on plants fitted for the food of man or of cattle, is as follows: That gentleman invented a heavy iron plough, resembling the common plough, but differing in this respect, that, having no mould-board, it splits the ground but does not turn it over; and he uses it thus:—at the same time that an ordinary plough goes along and turns over the surface of the wet land, the share of the subsoil plough following, passes through and splits the whole of the subsoil to the depth of 18 or 20 inches, and the rain water sinks, of course, so much lower. Mr Smith, however, does not allow the rain to lodge here: he has previously dug covered drains about three feet deep, made thus deep in order that his underground plough may have room to pass over the covered channel which is left for the water to flow along in the lower part of these drains after they have been filled in above; and he states that in this way he can not only produce, artificially, a porous subsoil instead of a close one, but that this clayey subsoil, having been so subdivided, becomes mellowed by the action of air and of water, and that thus, after a few years, a portion of it may be safely brought up by deep or trench-ploughing, and turned over upon the surface, so that the cultivated soil, by this third process, is to the same extent deepened. To whatever extent the Deanton system may be found applicable to the clay lands of England, a revolution will be at the same time effected in their mode of culture by the introduction of the turnip among them.

With regard to that portion of England which lies on a stratum that may be called rocky, much of it will be found to have the immediate subsoil of clay, and to fall therefore properly under the last head; and even where the subsoil is of stone, the stone may be so interspersed with clay, that thorough draining may be equally requisite. Where that stone is a dry gravel, it may be worth the trial whether the roots of some plants cannot be enabled to descend into it by means of the subsoil plough. Such an experiment appears, by a communication from one of our members, to have succeeded at Heckfield. A considerable portion of the stony soils belongs to the great chalk formation which, resting on the basis of Hampshire, flings its arms widely, in four directions, as far as the sea, through Dorsetshire, Sussex, Kent and Yorkshire. On this extensive tract another, and singular, mode of permanently improving the texture of the soil, by blending with it a part of the subsoil, has been

long and successfully, though very partially, practised. Pits, like wells, are sunk in the field, by workmen used to the business, and from the bottom of these the best sort of chalk is brought up with a windlass, to be afterwards spread over the surface; which thus, in the winter months, when the operation should take place, that the lumps of stone may be shaken to pieces by the frost, presents at a distance the aspect of a field covered with snow. The benefit of this rather expensive operation has been long acknowledged, though its mode of action has not been explained. It is less surprising, indeed, where the upper soil of the chalk formation consists of a thin layer of reddish clay, left behind by the plastic clay formation; but even where that soil is a shallow sheet of earth, that appears to be made up of fragments of the stone upon which it rests, this ancient practice of laying on a fresh coat of that very stone is stated to be equally advantageous. Enough, however, has now been said to prove how much remains to be done for the permanent improvement of the English soil. Indeed, while it may with truth be affirmed that our husbandry, on the large scale, stands in the first rank, as far as the surface of the ground is concerned, it must equally be admitted, as regards the subsoil, to be yet in its infancy. There is scarcely a situation where, however wet or dry, or stony, may be the natural ground, a kitchen garden, whose bed of mould two spades deep, may not gradually be formed by the constant, long continued care of the gardener. While the sand is stiffened, and the clay mellowed, and both deepened, the very stone is probably, by length of cultivation, worn down into soil. Nor can British husbandry be considered complete in this department until all the farms of this country, like those of Flanders, are brought into the same condition of garden-like temper and depth.

If we suppose the soil of a farm to have been provided with a free and healthy subsoil, the next subject to which the inquiry of agricultural science may be directed is, the manner in which that soil should be prepared for the reception of the intended crops; but it is unnecessary to do more than to touch upon one or two of the principal heads. The most simple and ancient of rural instruments, the plough though probably much more than 2000 years old, has recently received great improvement, and the best construction of it is even yet matter of controversy. There is no doubt that, by giving a more suitable curve to that part of it (the mould-board) which turns over the earth which has been detached with the share, and by substituting iron for wood on its surface, the friction has been so greatly diminished, that the new ploughs, being in other respects also of a far better shape, effect a diminution in draught, which may be estimated within compass at the saving of half a horse's labor on a team of three horses; and the Scotch or swing plough is now very generally used with two horses, the ploughman holding the reins. Nothing shows more the necessity of communication among the agricultural body than that the old cumbersome machines, with a huge carriage in front and two large

wheels, drawn by four heavy horses, should still be retained even on the light soils of some of our southern counties. Still it is yet a question whether the advocates of the swing plough have not gone too far when they have asserted that there is no land so stiff in which it may not be worked by a pair of horses; and it is indeed almost admitted that, on parts of the London clay formation, they have been beaten by the strength of the ground. It is even doubted whether one wheel might not be advantageously restored to the plough; and those ingenious mechanicians, the Messrs Ransome, of Ipswich, have constructed a plough which admits of being used without a wheel, with one wheel, or with two. These doubts should be cleared up with regard to different soils by observation; and it may be worth inquiry whether ploughs of different constructions, with different amount of horse power, may not be applicable to the same soil in various stages of cultivation, in first breaking the stubble, for instance, on heavy land, and in the cross-ploughings which follow. The other ancient implement, the harrow, is confessedly a most imperfect one, as its downward pressure is insufficient, and in the wrong direction, for cleansing from weeds the ground which it scarcely penetrates. Mr Finlayson's harrow, however, as it is called, though in fact a new and ingenious implement, is little used by practical farmers in some of our southern counties; but this harrow, as well as the further improvement, inadequately named a scarifier, is not only efficient for cleansing the land, but may sometimes be made also to supply the place of the plough. The use of another instrument, the drill machine, a more complicated one, by which the seed is laid in regular rows, has lately become frequent in southern as well as in northern England, though it has established itself so slowly, that for a long time, travelling machines of this kind have made yearly journeys from Suffolk as far as Oxfordshire, for the use of those distant farmers by whom their services are required.

But, before the seed is sown, manure must have been applied, either immediately or in some former stage of cultivation; and here questions large and numerous open themselves to the inquiries, and demand the experiments of a body which aims at raising the art of husbandry to the rank of a science possessing definite laws. Whether farmyard dung should be applied, recently made or in a more advanced stage of fermentation; whether it should be laid on the field in the autumn, and covered over for the winter by ploughing alternate furrows only—a process technically known as raftering, from the ribbed appearance which it gives to the field; or should be laid on in the spring, immediately before the turnip is sown; whether its efficacy be increased by mixing it in heaps with earth, technically known as compost heaps; whether the manure of a farm should be applied entirely to the green crops; or whether, as is a common course, recommended by the hope of inmediate gain, it should be shared by the wheat;—these are all questions in the minds of practical farmers, at least—as is shown by their opposite conduct upon these heads—which the science of agriculture, if it ever become a science, is bound therefore to answer. There is also, as to the very formation of farm manure, an important difference of management between ourselves on the one hand, and the oldest practical farmers, our neighbors the Flemings, on the other. The Flemish cattle are not allowed to run at large on the pastures, but are tied up in buildings, where

they receive a daily supply of green food newly cut, and a tank is formed near at hand, which receives the runnings of the stalls, and from which the liquid manure is carried in tumbrils to the arable ground. Not only are our farm-yards managed less closely in this important particular, but, as our cattle are in the field for a great part of the twelvemonth, it may be questioned whether their droppings do not in a great degree lose their fertilizing property by the action of the atmosphere as they lie scattered upon the surface. There is no doubt that, on the other hand, rank tufts of herbage are produced by the excess of manure in spots of ground upon which it falls. The advocates of the soiling system, as it is called, have acted upon that system for centuries, and they assert that a very large saving is effected by the uniform consumption of the grass, which is another result of this mode of management. A system backed by such high and ancient authority, must surely deserve inquiry into its merits. This last question, however, is a double one, involving on the one side the comparative amount of fertilizing substance produced for the use of the soil, and on the other the beneficial effect of the food on the condition of the animals themselves;—but this second branch belongs to a distinct head of inquiry—the feeding of cattle.

(To be continued.)

TRANSPLANTING TREES.

I notice in your valuable journal, an article in which one of the editors opposes his experience to the notion of a Boston brother, in regard to the proper time for transplanting trees. It may not be amiss to state for the benefit of those farmers who despise book-learning, that in this case, theory and fact agree. It is well known that all the food which plants draw from the soil, is absorbed by the extremities of the root fibres, or rootlets; and that the difficulty of transplanting, arises from the impossibility of preserving all those fibres, whatever care may be used in the operation. When a tree has been moved, it is deprived of a portion of its nourishment, till new fibres have been emitted from the roots in sufficient numbers to supply the place of the injured ones; and if many have been broken, or the tree is not able to replace them quickly, it languishes and dies. The best time for transplanting is evidently that at which plants are in the best state to emit new fibres, and best able to subsist with little nourishment from the earth; and the worst that at which these conditions are reversed.

In autumn, trees are employed in laying up a store of food for the coming year. As the leaves fall off, the sap thickens, deposits a saccharine substance on the sides of its vessels, and finally entirely ceases to flow, and the tree becomes torpid and remains lifeless through the winter. This then is not the time to transplant. Young trees may indeed be taken up at this season, and having been kept in doors, may be set out again in the Spring, without danger. But it is quite a different matter to put a plant into the ground when all its powers are going to decay, and it is not able to form a single new fibre, or even to preserve those it already has. Except for the shelter from the cold which the dirt round its roots affords, it might as well be exposed to the winter on a bare rock. In spring, however, the case is quite different. Then the plant derives its nourishment in a great measure from the saccharine matter deposited the preceding year, and is employed in putting out new fibres to

absorb sap from the earth, and new leaves to elaborate it. If moved at this time, its means of life are hardly affected at all; only its situation changed. Evergreens, however, may be transplanted at any time except when perfecting their foliage they have a constant flow of sap.

If you will allow me, it may be well to mention some other results which follow from the principles mentioned above. One of these relates to the proper time for cutting timber. The winter is not the time; for then the wood contains more solid matter than at any other season. It is the soluble saccharine matter contained in timber, which its easy decomposition, induces that of the wood fibre.

The liquid sap evidently has nothing to do with it, for it is all dried out in the process of seasoning. What is the best time, may admit of a question; but it must be after the saccharine matter has been exhausted in the spring, and before it has begun to be deposited again in the fall.

Trees should also be pruned in the spring, when new wood is forming; for then the wounds soon heal; and the plants being in their flourishing state, are best able to bear injury. A wound made in the fall, remains open and exposed to the influence of air and water till the season. For the same reasons grafting should be performed in the early part of the year, though till the sap is in full flow.—*Jour. of Com.*

THE CONSERVATORY.

We advise our friends who are seeking amusement, to look in at the Public Conservatory. There are above one thousand *Camellia Japonica* in some of the largest now in full splendor, and on the point of bursting their beautiful buds. A them are at least twenty full grown trees. We well know that the former possessor of this collection of *Camellias*, M. P. Wilder, of Dorset, spared neither pains nor expense to procure the finest plants from the justly celebrated nurseries of Europe, and that the most recent and most esteemed seedling varieties are comprised. But it is too well known that one of his motives in disposing of this collection to the society at a pecuniary sacrifice to himself, was, the desire his fellow citizens might conveniently and freely enjoy the pleasure of viewing it. It is estimated that during the next five or six weeks a thousand *Camellia* blossoms will expand—here are now in full bloom and contrast beautifully the dark glossy foliage, the perfect cleanliness which is highly creditable to Mr Donald, the tender. Several of the *Acacia* tribe, the prettiest of the *Flora* of New South Wales, are likewise beauty—as is also the fine *Poinsettia pulchra* named in compliment to our former minister to Mexico, Mr Poinsett, who sent it thence to Canton, in 1828, whence it found its way to London. This plant was presented by the Hon. John Lubbock of Roxbury. We are also informed that the city has recently received ten or twelve capital plants from Rio Janeiro, containing about a dozen varieties of the curious *air plants* now drawing so much attention in Europe; most of them beginning to vegetate in a small stove erected for this purpose below; these will no doubt be added in the Conservatory as they come into port. We trust the public will not fail liberally to support this establishment, which promises to be an ornament to the city.—*Transcript.*

From the Farmer's Monthly Visitor.

FINE WOOLED SHEEP.

Hopkinton, March 1, 1830.

Dear Sir:—I have seen in the last number of your Farmer's Monthly Visitor, page seventh, an account of the purchase and stocking with sheep the Burleigh farm in Dorchester, by President Ford, of Dartmouth College. In the account given, a very unfavorable allusion is made to the fine Merino and Saxony sheep, as requiring the utmost care and the most tender treatment. I also find in the second number of the same work, page eighth, a declaration that the native New England sheep are more hardy and less liable to disease, than the finer breeds; and that an opinion is suggested that they may be kept at as good advantage. I am not prepared to say that the native sheep of this country may not be raised by the farmer at a profit, if they can be found; but I know none that are not more or less mixed with the other kinds. I greatly misjudge, if the advantage is not very much in favor of the finer breeds, and the finer the greater the profit. I am also extremely deceived if they are not kept through the year at as little expense as the natives, and at much less trouble. Native sheep are uniformly plump, lank, and coarse woolled; untame, great eaters and expert jumpers; vexing their owners, and frequently the whole neighborhood by visiting every field and enclosure they wish. The Saxony and Merino sheep, which produce the finest wool that is known in this or any other country, are shorter legged than the native breed, more round and plump in every part of them, and easily attended. They are more quiet and peaceable in their disposition, and with ordinary care of fences, seldom if ever stray from the pasture where they are put. They afford mutton equal to any other kind; their quarters being round and full, mild, tender, and fine flavored. They are the smallest sheep I have ever known. This I consider an advantage rather than a disadvantage. They are not like our oxen required to perform labor. They are kept for their flesh and fleece only, and from long observation I am convinced that it requires the same quantity and quality of food to make a hundred pounds of mutton, or a hundred pounds of wool, whether, it be given to small or large sheep.

As regards diseases of fine sheep, I know of none that may not be visited upon the natives, which are equally liable when brought together in large flocks. In my own flock I have never known any contagious disease, if I may except a flock of fine sheep of one hundred and twentyone which I took in the fall of 1829, for the term of one year. When I took this flock, they were all diseased and lame with the foot-rot. I found them extremely poor, and some of them unable to walk, and feeding upon their knees. During the year I lost nine of them by poverty and disease, and two by casualty. At the expiration of the term I divided equally with the other owner one hundred and ten old ones, and at the thirds, thirtysix lambs, all perfectly healthy and in good order. With this exception, I have never known any contagious disease to trouble any sheep I have had the care of. I seldom lose one in any way, and am equally fortunate with my lambs, when not troubled by foxes. At the yearning season of 1830, one fox killed from my flock and carried to her young, seventeen lambs in four days and nights. I had a number killed at

other times, and my loss in lambs by foxes that season was from fifty to sixty dollars.

I am one of those who believe things should be told as they are. I should feel hurt were I to lead any one astray from his interest by any thing that I have said, and as some proof of the truth of the foregoing, I here give an account of the income of my own flock. My average number of sheep at the shearing season in eight years, from 1821 to 1830 inclusive, has been two hundred and fortyone. I have received in cash for sheep and wool sold from my flock during that time, four thousand, five hundred eightyfour dollars and seven cents; giving a yearly income of five hundred seventythree dollars and one cent, or at the rate of two dollars thirtyseven cents and a fraction a head, a year.

When it is considered that six small fine sheep may be kept on the same food that would be required to keep five coarse ones, which I have no doubt is short of a reasonable estimate, a preference for the fine flocks will be more apparent.

I shall be likely to retain my partiality for fine sheep till some one gives an account of a more profitable flock of coarse ones of an equal number.

STEPHEN SIBLEY.

For the New England Farmer.

BERKSHIRE PIGS.

MR BRECK:—As many impositions have been palmed off on my brother farmers who have purchased what we called Berkshire pigs, I am induced to state a few facts and offer a few thoughts on his subject. Many pigs have been sold from droves passing through this State, Connecticut and Rhode Island, which do not resemble the true kind only as they have some black bristles mixed with white; some nearly all black, of common breeds, have been sold for pure blooded Berkshire. Some drovers have bought up a lot of rants, unfit to breed from, in Albany and its vicinity, because they could be obtained cheap, and sold them out as they passed through the country, while some men in the vicinity of Albany, (Mr Bement informs us), do not hesitate to sell half blood for the pure blooded Berkshire, they also are disposed of among the farmers, and the impositions are calculated to create a prejudice against this excellent breed of hogs,—for after seeing a pig called Berkshire, supposing it a fair sample of the breed, many have supposed them no better than the common breeds. In view of these facts, I would suggest the propriety of our farmers visiting some establishments where the pure bloods are bred, and examining pigs that have been obtained of honorable breeders, before they reject the Berkshire hogs. We also think breeders ought to select the very best to breed from, and breed from them only, that the breed may improve instead of degenerating.

We are pleased with the principle adopted by H. S. Ramsdell, a breeder of Berkshire hogs in West Thompson, Ct., who breeds only from the very best, and in supplying orders for pigs, sending only those worthy to be bred from, reserving the inferior ones for the knife. Mr Ramsdell has taken great pains to obtain a lot to breed from, of the best form without regard to price. We visited his establishment not long since and found some of the best pure blooded Berkshires we have ever seen. At the fairs we have attended, or breeding establishments we have visited, we have never seen their equal: several persons in the adjoining towns

who have purchased Berkshires previous to seeing his, engaged pigs of him on account of the stock being superior to their own.

We could but admire the fine form of a grandson of Mr C. N. Bement's son 'Stately' Mr R. informed us it was then 9-12 months old. On the tape being applied, we found the length from nose to root of tail, 5 feet 3 inches. I ought to add, as the residence of Mr Ramsdell is but one mile from the Norwich and Worcester railroad, our farmers along the railroad from Thompson to Boston, might conveniently supply themselves with pigs from his establishment. E. D.

Webster, Jan. 1, 1830.

WITCH GRASS.

MR EDITOR:—Some of your correspondents have been striving to rid themselves and their neighbors of that troublesome weed, witch grass. Now I happen to know from experience one of the easiest and most profitable methods of destroying this grass.—This grass will never increase in pastures. It always finds its way into such land as has a warm light soil, and is most cultivated. Land abounding in this weed should be immediately converted to a sheep pasture, and in a few years it will be entirely eradicated.

My father once took a piece which was thickly set with it, ploughed it late in June, sowed it with winter rye and turned it into his sheep pasture.

The rye continued to come up for a year or two and was kept closely fed by the sheep, and in a few years the witch grass was exchanged for sweet clover and red-top. I doubt not but that this plan might be adopted to advantage on many farms that are overrun with this useless weed. It is folly to talk of digging it up when it has obtained a firm foothold. Land that is of a light thin soil can be changed from tillage to pasturing to great advantage. Pastures would be improved in this way, for it is bad economy to possess a pasture that will give only now and then a spot that cattle will touch.

Another method I have seen practised in ridding small garden spots of this grass, which is by laying boards closely over the ground for a season. This is much easier than to dig it up. While on this point I cannot help noticing one fault among gardeners. They are very anxious to prevent the weeds from going to seed during the first part of the season, but as soon as the plants get a little start, they suffer the weeds to take their own course. Consequently there is a fresh supply of seed for the succeeding spring.

If some of your correspondents will counsel me in killing thistles with as little labor and as much profit as I have advised them in killing witch grass, they will receive my sincere thanks.—*Farmer's Register.*

The Dahlia is a Mexican plant, and was introduced into this country about thirty years ago.

The average price of flour through the country at the last dates was \$5 48 per barrel.

The Albany Evening Journal says, that a line of 225 boats, some days ago detained by the ice west of Utica, in the canal, were in motion, and approaching Albany, with flour and other merchandise to the value of nearly half a million of dollars.

HARD TIMES.

The following beautiful and eloquent remarks on the subject of hard times, are copied from an American magazine published in 1787. We know not who is their author, but they are worthy of the greatest of writers; and we republish them, as not altogether inappropriate to the manners and customs of the present times.—*Bost. Weekly Mag.*

"The scarcity of cash is a general complaint, and it has become so fashionable to complain of hard times, and the scarcity of money, that debtors seem to think that they have sufficiently satisfied their creditors, if they tell them the times are hard and money scarce. This has so long been the theme, that the people almost universally believe it, although it is a falsehood. Every generation and age thinks the former days and times were better than the present. This, however, is a mistake, founded on false surmises and vain imaginations. The original principles of human nature are the same in every age, and ever have been since the fall. Times are easy when men do their duty; but when they deviate from that, and enter the road of vice, indolence and licentiousness, then difficulties embarrass and troubles perplex them.

The complaint of hard times in this country is all imaginary. Indolence and extravagance in dress are the source from which all the evils so bitterly complained of, flow. Both reason and revelation teach us that the human race were to live in this world by industry, and to earn their bread by the sweat of their brow. On the productions of the earth we depend for subsistence, and spontaneous productions are not to be expected. The earth must be cultivated before she will yield her increase. In a country like this, it cannot be expected that all the inhabitants should live by commerce; nor indeed but a very few in proportion to the whole. Yet in this country, the people, as it were, drunk with the idea of gain, if they can but get into the mercantile line, are crowding into it, and to appearance seem to think that the whole community can live by buying and selling European gewgaws. This, however, is a mistake which time must teach and reform. Experience is the only teacher mankind will believe; and when they have learned by a fair trial, that indolence and craft will not support them, they will turn to industry, and lead quiet and peaceable lives, in diligence and honesty.

Agriculture is the very soul and life of this republic; if that is neglected, difficulties will certainly arise. Our own manufactures must also be encouraged and carried on, if we mean to be a happy and independent people. For a few years past the farmers have to appearance, been vying with the merchants in dress. They have neglected to manufacture their own wearing apparel; because, say they, our own manufactures are not so handsome as foreign, neither are they so durable or cheap. By this means they have reduced themselves to poverty, and now loudly complain of the hardness of the times. A different line of conduct must be adopted; industry and frugality must be the stability of our own and all other times.

In a free and independent state, where republican principles and sentiments are adopted by the people at large, the idea of equality breathes through the whole, and every individual feels ambitious to be in a situation not inferior to his neighbor. Among us the idea of inferiority, as of pursuing a mean employment or occupation for a livelihood, mortifies

the feelings, and sours the minds of those who feel themselves inferior; and consequently the poor to their great injury, strive to be equal to the rich in dress, if in nothing else. The farmer in the field will be found clad in as delicate a garment as a merchant behind his counter. This is utterly wrong and cannot be supported. Let every one dress according to the business he is in. If a man's business is to measure off cloths, and deal out clean elegant goods to customers, he may, as well dress neat and elegant as otherwise, and propriety dictates that he should. But if his employment be in the field, to plough and cultivate the earth, a different dress becomes him; and the old adage will ever hold true, "He that will increase his riches, must not hoe corn in silk breeches." A frock and trousers are as becoming a dress for a farmer when laboring in the field, as a ruffled shirt, a velvet or silk vest and breeches, and a superfine broadcloth coat, are for the merchant in his shop. There is propriety, uniformity and beauty to be observed in every thing, and every thing is beautiful in its proper place.

The other day I went to see some farmers who owed me a trifle, and found them in the field at work. One was clad in a velvet vest and breeches, and fine worsted stockings—the other in a satin vest and breeches, worsted stockings and a fine Holland shirt, with a ruffie at the bosom. I asked them for the money they owed me; and was told "money is exceedingly scarce; the times are very hard; and it is an impossible thing to get money." I offered to take stock or almost any other article; but they had nothing to pay me except land, and that they could not spare; and so my debt was discharged by inability. The reason why I mention this circumstance is to shew that the extravagance of people to decorate their bodies is the origin of their poverty; and the hardness of the times arises from a foolish pride. Every man is honorably dressed when he is dressed suitably to the business he is doing.

Agriculture by some is thought a very mean employment; yet those who esteem it such, I will venture to say are mere simpletons, and the true principles of honor are not in them. Is it more honorable to be servant to every body, to weigh but an ounce of indigo, to draw a quart of molasses, than to cultivate the earth, and reap the yellow harvest—to procure the necessaries and luxuries of life? The employment of a farmer is really the most honorable of any on earth. Where or what would be the mechanic, the lawyer, the physician, or the merchant, if it were not for the farmer?—Where or what would be the statesman, the prince, the emperor or the monarch, with all their brilliant equipages, were it not for the farmer? The branches are not so honorable as the root; let them not therefore, boast of their own gaudy appearance, and despise the root that bears them. The husbandman, surely, is worthy of much honor, as he is the foundation on which kingdoms and empires stand. Monarchs and emperors are supported by the industry of the husbandman, and all their greatness stands on his shoulders. Let him, therefore, be honored and respected, that his heart may be encouraged and his hands strengthened in his laborious and tiresome work."

A farmer at Gaysport, Pa., raised this season 800 bushels of potatoes from an acre and a quarter of land.

From the Farmer's Cabinet.

FARM ACCOUNTS AND FARM PROFITS

Mr Editor—I was much pleased with the communication in your last number from A. E. T. of Philadelphia county, and I am glad that an article so plain, interesting, and calculated to place the profits of agriculture in a fair light, is to be followed up, as I infer from the heading of the piece which is No. 1. Now I do hope that this writer who it appears can hold the pen as well as the plough, will continue his essays for the benefit of his brother farmers. There are many subjects of great interest to the farmer that have as yet received little or no attention from agricultural writers. The subject of *Farm Accounts* is one of great importance, and I trust that A. E. T. will furnish us with a bird's eye view of his system which I presume is a good one.

The system or practice of farming with us in Montgomery county is not essentially different from that in the more immediate neighborhood of Philadelphia—but our great error has consisted in not farming well enough; we have been too anxious to have large farms, even if partially cultivated, in preference to small ones in a high state of fertility. The desire to own many acres, has been the ruin of hundreds, and was the rock on which I was nearly shipwrecked. Some years since, when money was cheap and every thing saleable dear, I was induced to believe that my farm of ninetyfive acres was too small. True, I had lived above board, and entirely free of debt, and had abundance of employment; but still my farm was small, very small, indeed almost insignificant in comparison to some of my neighbors. Instead of being contented with what I had, and by still greater attention causing to produce more abundantly than it had previously the spirit of grasping after more, ambition, speculation, or whatever you may please to call it, to full possession of my mind—of course my days tranquility were ended.

About this time it so happened that an adjoining neighbor had become a victim to the spirit of emigration, and having settled on locating in the west, offered his farm for sale. He had been revolving in his mind the propriety of this step for several years, and as it worked upon him, his farm became more and more neglected, until, in some measure, he lost the character of a clean farmer. The buildings on the place were so old and decayed, that they were considered of no value. The farm consisted of two hundred and twentyeight acres, subject to a mortgage of six thousand dollars, at five per cent, payable half yearly. This was no obstacle in my mind, "as the mortgage may remain years." The day of sale came, and I was the fortunate purchaser; it being knocked down at one thousand one hundred and twenty dollars, subject to the aforesaid mortgage. My farm of ninetyfive acres, had in the nine years I tilled it poorly, yielded me about two hundred dollars profit per annum, so I had about eighteen hundred dollars at command, but was compelled to borrow, a thing I never did before, about four hundred dollars.

I had now attained apparently the summit of wishes—I was now a large landed proprietor!—first, I little thought of the collar on my neck in the shape of a mortgage, and sundry small obligations shortly to be met. I enjoyed myself finely indeed, but only for a short time, as the bubble burst, and I awoke to the cold and sober realities of my situation.

ion. True, I was a large proprietor, but that did not give sleep to my eyelids. My six months' interest came round, and was paid after many days' vexation. My coming crops, which fortunately were pretty fair, enabled me to keep along for that time, to support my family, and pay off the four hundred dollars; but it took all, and when that was gone I was in a deplorable condition. A large plantation, mostly in a bad state of cultivation, with poor fences, grew rapidly to decay—the soil requiring a liberal application of enriching manures to give it life, and no money to purchase it, or to pay for sufficient help. But I resolved not to be discouraged, and though, by going into debt for various articles where I had credit, I was compelled to pay an enlarged price, yet I pushed on, resolved to do my best to weather the storm, and improve the purchase, at least in appearance, such as fences, &c. But instead of cultivating but a part, I very foolishly—no I fear is the case with too many of my brother farmers who occupy too much—undertook to cultivate the whole—the consequence was that my crops were generally light, especially on the new purchase, and not so good by odds, on the homestead. I saw my error, and determined, if possible, to retrieve it. By perseverance I was enabled to continue and make both ends meet, but as to laying up a dollar, I did not and could not, and I had almost become reconciled to my toilsome and care-worn life, when I was started on a new track.

In 1836 a young man, a stranger, who was soliciting subscriptions for an agricultural work, called at my house about evening. I bid him to stop for the night, which he did. In the course of the evening our conversation—confined as it was to agriculture—turned upon my embarrassments. Why, said he, it is the easiest thing in the world for you not only to slip the collar, but to do it to this purpose. I inquired how: he replied—Sell enough not only to pay your mortgage, but to enable you to lay in a noble stock of manure, and devote the same cost, labor and attention on what you have left as you did on the whole, and I will guarantee you success. But I can't sell—I have tried the neighbors for years, to no effect. But that is not the way—advertise, yes, advertise very extensively, not only in your county papers, but in those of the city, and the surrounding country; make your farm known every where. Sell off the first chance. He read me several articles about the profits of small farms well managed—of the great improvements in agriculture, &c.

In the morning I subscribed for his paper. He went his way, and I turned my attention to the duties of my farm. But his advice made so great an impression on my mind, that I could not rest until I had made the effort to sell in the manner he proposed. I accordingly encountered the expense; and one of the advertisements fortunately brought me a purchaser, cash in hand, who took two hundred acres at forty-three dollars per acre, or eight thousand six hundred dollars; so I had a trifle left, besides twenty-eight acres of wood land. I was at once released from my trouble—but the gain—much as it may seem to some, can never recompense me for the intense suffering of mind which for years I had endured.

I promised my wife and children, that if ever I got well out of that speculation, that they would never find me engaging in another; and I will preserve my word inviolate. I immediately set about arranging for future operations. I was liberal in the application of manures to my old place—

my fences were all put in excellent order—out-houses repaired, and all about or around the dwelling neatly whitewashed—better accommodations were made for cattle, &c. and now the old homestead not only looks as pleasant as ever, but is the abode of real contentment and rural enjoyment.

But this is not all—reading my agricultural works has stimulated me to endeavor to keep pace with the improvements—and what is a mystery to some of my neighbors is, that now on the old "ninetieth," as they call it, I raise more saleable or disposable produce than I ever did, with the addition of the large farm. This is a fact. But it is easily explained: the three hundred acres were partially cultivated—the homestead is now in the highest state of fertility, and I have from the free use of lime been under the necessity of contracting for an additional barn on the premises. Before I purchased the addition, I laid by about two hundred dollars a year, but when I cultivated the whole I could scarcely make both ends meet. Now I can, thank Providence, doing better than ever. I am doing well, and intend to "let well enough alone," and not be led away by a spirit of emigration, the mulberry mania, or the making of beet sugar. I shun these things as I would a pestilence, but shall content myself with raising the sugar beet for my stock, which is increasing, satisfied that nothing is better calculated for them, or more advantageous for the farmer—the stock farmer especially.

Now I am going ahead without keeping accounts save certain memorandum books. I feel the want of a correct system, and I hope that your correspondent "A. E. T." or some person competent to the task, will furnish through the Cabinet, the information desired, for I consider it almost as important for the farmer to have a correct system of accounts as it is for the merchant or mechanic. J. J.

THE COTTON CROPS OF THE WORLD.

There is no subject connected with commerce or agriculture, which possesses a higher interest for the citizens of the United States, than the production and consumption of cotton. We have, on more than one occasion, devoted our columns to the insertion of information upon the subject; and our attention is particularly called to it just now, in consequence of a recent publication of a valuable letter, signed "Cotton Plant," in a spirited New York paper, called "The Whip." The writer commences by stating that the entire growth of cotton in the world is set down at 1,000,000,000 lbs. Of this 550 millions are supposed to be grown in the United States, 30 in Brazil, 8 in the West Indies, 27 in Egypt, 33 in the west of Africa, 190 in the West of Asia, 35 in Mexico and South America, except Brazil, and 14 millions elsewhere.

Thus, at 10 cents per lb., a price below which it has rarely ever fallen, this crop is worth 100,000,000 dollars. For the last fifty years, however, the value (though often fluctuating suddenly and widely) has averaged 19 1-2 cts. At this price the present growth of the world is worth \$192,500,000.

Of this, about 350 millions of pounds are consumed and manufactured in England, about 150 millions in the U. States, 80 in France, 250 in China and India, 25 in S. America and Mexico, including Brazil; 35 in Germany, 45 in Turkey and Africa, 10 in Spain, 20 in Russia, and the remainder elsewhere.

The value of cotton manufactures in England is believed to be annually about 170 millions of dol-

lars; in France at 70 millions; in the U. States at 60 millions.

The capital employed in manufacturing by machinery, is estimated in England at 200 millions of dollars; in France at 120 millions; in the U. States at 110 millions.

The consumption in manufactures of raw cotton in all Europe, in 1833, was estimated at only 60 millions of pounds. (Dic. of Span. Com.) The whole consumption in Europe, in 1830, was about 387 millions of pounds. In 1838, it is believed to be nearly 500 millions of pounds.

South Carolina and Georgia were the first states in this Union to grow cotton to any considerable extent. In 1791, two millions of pounds were grown in the Union—one and a half million of which grew in S. Carolina, and one half million in Georgia.

In 1801, forty millions was the crop of the United States—of which 20 millions grew in South Carolina, 10 in Georgia, 5 in Virginia, 4 in North Carolina, and 1 in Tennessee.

In 1811, the crop of the U. States had reached \$0,000,000—of which 10 grew in S. Carolina, 20 in Georgia, 8 in Virginia, 7 in N. Carolina, 3 in Tennessee, and 2 in Louisiana.

In 1821, one hundred and seventy millions of pounds were growing in the Union, as follows: 50 millions in S. Carolina, 45 in Georgia, 20 in Tennessee, 20 in Alabama, 12 in Virginia, 10 in North Carolina, 10 in Louisiana, and 10 in Mississippi.

In 1828, the whole crop of the Union was 348 1-2 millions. Of this Georgia grew 75 millions, South Carolina 70, Tennessee 45, Alabama 45, Louisiana 38, Mississippi 20, Virginia 25, North Carolina 18, Florida 2, and Arkansas one half of a million.

In 1833, the crop of the Union had increased to 437 3-4 millions. Of this, 88 millions grew in Georgia, 73 in South Carolina, 70 in Mississippi, 65 in Alabama, 55 in Louisiana, 50 in Tennessee, 15 in Florida, 13 in Virginia, 10 in North Carolina and three fourths of a million in Arkansas.

The next year, 1834, the crop had increased to 457 1-2 millions, and was grown as follows: 85 in Mississippi, 85 in Alabama, 75 in Georgia, 65 1-2 in S. Carolina, 62 in Louisiana, 45 in Tennessee, 20 in Florida, 18 in Virginia, 1-2 in North Carolina, and in Arkansas one half a million. Subsequently, no certain data are in our possession; but the estimate at this time, is 550 millions as the whole crop of the Union.

Thus it will be seen, from 1791 to 1836, S. Carolina was the most abundant cotton growing state in the Union. In 1826, Georgia took the lead, and held it till 1834, when Alabama and Mississippi took the front rank. At this time, Mississippi is perhaps the most extensive cotton growing State in the Union. South Carolina and Alabama are next. North Alabama is beginning to deteriorate as a cotton country, while the worn lands in middle Tennessee are thought to improve for this culture—maturity, the vital desideratum, not being so easily allowed in the rank luxuriance of the fresher soils.

When it is remembered that the first cotton plant in the United States was raised in 1787, surely our readers will find reason for surprise at the wonderful increase that has accrued in little more than fifty years! Bold, indeed, must be the man who would venture to predict the wealth, greatness and power, likely to become our national attributes through the agency of cotton.—*Philad. Inquirer.*

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JANUARY 8, 1840.

To the Trustees of the Massachusetts Society for Promoting Agriculture.

The Committee appointed to examine the claims and award the premiums on butter and cheese, exhibited in Boston on the 3d and 14th of December, 1839.

REPORT.

That, judging from the very diminished competition for the liberal premiums on both these articles, they are forced to conclude that the interest of the agricultural community in this exhibition has very much decreased.

In the exhibition of December, 1837, there were 54 entries of butter, and 16 of cheese, the amount of butter being estimated at thirty thousand pounds. On the late occasion there were 15 entries of butter and 8 of cheese, the quantity of butter being probably about 5000 pounds only.

In this absence of competition the Committee thought it their duty to fix, as a standard of excellence, that quality of butter which their experience has taught them may be attained; and keeping this in view, they were not satisfied that any of that presented was of first rate excellence. They believe that they have seen and tasted better dairies than any which came before them, and they therefore determined, under the standing rule of the society relative to premiums, to withhold the first premium of one hundred dollars, and to award gratuities to two very good lots of butter after distributing the second and third premiums. They proceeded on a similar principle in regard to old cheese, of which only two lots were presented, both in their estimation very respectable, but not superior.

After thoroughly examining and remarking upon the several lots, in which they were kindly aided by the experience and judgment of Messrs John Hurl, Elijah Cobb, and N. A. Thompson, they unanimously awarded, to William Bachop, of Barnet, Vt., the second premium of fifty dollars for his lot of butter No. 10; to Luther Chamberlin, of Westboro', Mass. the 3d premium of thirty dollars for his lot of butter No. 8; to Daniel Chamberlin, of Westboro', a gratuity of twenty dollars for his lot of butter No. 6; and to Richard Hildreth, of Sterling, Mass., a gratuity of fifteen dollars for his lot of butter No. 3.

The premium of thirty dollars on *new* cheese the Committee unanimously awarded to Timothy Fisher, of Burke, Vt., for his lot No. 5; and a gratuity of twenty dollars, to the same person, for his lot of old cheese No. 6.

To David Lee, of Barre, they awarded a gratuity of fifteen dollars for his lot of old cheese No. 4; and to Ebenezer Tidd, of New Braintree, a gratuity of fifteen dollars for his lot of new cheese No. 7.

From the remarks of the Committee on the several lots of butter, it appeared, that in each there was more or less of neglect or error in the making or in the preservation of it. A very prominent neglect in *making* is that by which butter milk in any quantity is suffered to remain in the butter. It is a well settled principle that this is fatal to its preservation. No quantity of salt can prevent that substance from becoming sour and causing the butter to grow rancid. It can be all separated from the butter and it undoubtedly ought to be.

A very prominent error in preserving butter arises from the excessive use of salt. No more of this need be added to well made butter than is sufficient to make

it palatable; but as this standard varies with the taste of different individuals, it is perhaps safest to use it sparingly, since no quantity can repair the evil of defective making.

The use of sugar in curing seems to be sanctioned by the best writers on the subject; but the Committee are of opinion that it should be employed in smaller quantities than is usual. When it is distinctly tasted it impairs the natural sweet flavor belonging to good butter, and is, in all cases, a poor substitute for it. It is also highly probable that in time it may become accented.

On the whole the Committee cannot but exhort their agricultural friends to aim at a higher standard—to exert more care in the making as well as in the preservation of butter and cheese, persuaded that it is a branch of industry which will repay the labour bestowed on it.

December 14, 1839.

H. CODMAN.

We have the pleasure of laying the foregoing report before our readers, and of joining in the regrets which it expresses, that the competition for the magnificent premiums of the Massachusetts Agricultural Society is very limited compared with what it should be.

That the competition from other States is not greater, arises from several reasons—the first probably is that the offers of premiums are not generally known in other States; or if heard of, it may not be known as generally that the competition is open to all persons. Another reason is, that distance prevents a competition from the great dairy States of New York and Pennsylvania, besides that their home markets furnish a quick demand for all the dairy produce which they make. It is true there have been claims heretofore from both these states; but this was rather accidental, the farmers who made the claims having had personal friends in Boston or its immediate vicinity, to take charge of samples when sent.

Why the competition is not greater from Massachusetts is owing to other reasons. Berkshire county may be considered as the principal dairy district in the Commonwealth. But the commercial relations of Berkshire county are almost exclusively with New York; and there their butter is sent weekly, and their cheese with as frequent dispatch as the nature of the article will allow. The distance of the principal dairy portions of Berkshire county are little more than a half a day's journey from Hudson on the Hudson. Here the farmers convey their produce as often as it is in condition; it is then put on board the boats, and is in New York market in excellent order the next morning; and sold and the boxes returned for a commission of one or two cents a pound. It is to be considered, likewise, that the dairy husbandry of Berkshire county has been greatly reduced from what it formerly was by the introduction of sheep; and by another reason felt all over the country, the impossibility of procuring dairy women. The country is actually stripped of this portion of its population by the various factories, by the demand from schools for female teachers, from the cities for dress-makers and servants, by the traders for strawbraiders and shoebinders, and by other occasions of demand; so that a female domestic or dairy maid is almost as rare as a cucumber in January. There seems to be no getting them upon any terms short of direct proposals of marriage; and at present we see no remedy in prospect, unless our Legislature in its parental concern for public comfort, should revive the good old patriarchal custom of polygamy, when Abraham had not only his Sarah but his Hagar also! We dare not advocate such a proposition, and feel that there may be some peril in even making the suggestion.

In Worcester county, which next to Berkshire, is the principal dairy county, the dairy products are sent market as frequently as the case will admit; the butter every week and the cheese as often, and as soon as it is dry enough to hold together. It brings then as good price as at any time, and the greener it is the heavier weighs. Under these circumstances, few farmers are willing to come into a competition where so large a sample as three hundred pounds is required of the claimant. They cannot do it in many cases without disappointing their customers of their weekly supplies, which is a serious evil to both parties. Nor can they do it (unless they should obtain the premium,) without an actual pecuniary loss. For example, two of the competitors of the present year could have sold the butter which they presented, every week at 33 and 37 1-2 cents per lb. We know that the butter from these dairies brought these prices through the season; and the supply did not equal the demand. Now taking into consideration the increased trouble and expense of packing their butter for keeping, the disappointment of their customers, the uncertainty of obtaining the premium, and then too of the price which they may obtain for their butter at the public sale after the exhibition, which, if we remember correctly, in the two cases referred to, was only 28 cents, it will be seen that the motives to competition are very much diminished. The same remarks apply in a degree to the cheese, which in general is sent to market once in three weeks; and which cannot therefore be kept by the farmer for exhibition but at a loss, unless he should be fortunate enough to gain the premium, and then he may not be fully indemnified, though the distinction may not only gratify his honest pride but give a celebrity to his dairy, which may afterwards be of much use to him.

The size of the premium, though expected to operate a directly contrary effect, has a tendency to discourage competition. A premium of one hundred dollars is large affair in the eyes of most of our farmers. They are discouraged in the attempt to compete for it, for some undefined notions of the impossibility of obtaining it. To divide it therefore into three or four, would tend greatly to increase the number of competitors, without at all lessening the pains which would be taken to gain it in the preparation of the butter or cheese. The advantages of the honor in the sale of the butter or cheese are a sufficient compensation for any extra trouble.

We respectfully suggest, therefore, to the Trustees the expediency, for reasons above given, of dividing the premiums into a larger number, so as to encourage wider competition; and to reduce the quantity required for exhibition, so as to open the competition to a class of farmers, who, for circumstances above named, would decline it. It is not the quantity produced that is the object of the society in the offer of premiums; but the quality of the product and the best modes of excellence in this matter; and these points would be reached by specimens of from fifty to one hundred pounds, as certainly and as well as by three hundred pounds of the dairy product.

The principles and views of the report perfectly accord with our own views. It must not be inferred, however, that the butter of Mr Hildreth, Mr Bachop, and the Messrs L. and Daniel Chamberlin was not of an excellent quality. But we do in our own name, as the committee have done in theirs, enter our absolute and uncompromising protest against allowing any butter milk to remain in the butter; against using salt too profusely; against using any saltpeper; against sugar in any measure whatever; and against any coloring matter, especially a painter's drug or any thing unless it be the simple juice of the carrot. We say this particular

MISCELLANEOUS.

NATURE.

BY ROBERT C. WALTERSON.

I love thee, Nature,—love thee well—
In sunny nook and twilight dell,
Where birds, and bees, and blossoms dwell,
And leaves and flowers;
And winds in low sweet voices tell
Of happy hours.

I love thy clear and running streams,
Which mildly flush with silver gleams,
Or darkly lie, like shadow dreams,
To less the sight;
While every wave with beauty teems,
And smiles delight.

I love thy forest deep and lone,
Where twilight shades are ever thrown,
And murmuring winds with solemn tone,
Go slowly by,
Sending a peal like ocean moan,
Along the sky.

I love to watch at close of day,
The heavens in splendor melt away,
From radiant gold to silver gray,
As sinks the sun;
While stars upon their trackless way,
Come one by one.

I love, I know not which the best,
The little wood-bird in its nest,
The wave that mirrors in its breast
The landscape true,
Or the sweet flower by winds caressed,
And bathed in dew.

They all are to my bosom dear,
They all God's messengers appear—
Preludes to songs that angels hear—
Mute prophecies—
Faint types of a resplendent sphere
Beyond the skies!

SILK FROM THE SPIDER.

In a late number of Chambers' Edinburgh Journal, there is an interesting article on the subject of Silk from the Spider, from which we make an extract:

"Some years ago the Society of Arts conferred one of their honorary medals on a gentleman of the name of Rolt, for obtaining silk from the garden spider, *aranea diademata*. This is the insect whose webs in autumn are so conspicuous on the surface of shrubs, and in other situations. On allowing one of these animals to crawl over his hand, Mr Rolt found that it drew a thread with it wherever it went. He likewise, without any difficulty, wound some of this thread over his hand, finding that the spider continued spinning while the thread was winding up. On this hint he connected a small reel with the steam engine of the factory in which he was occupied, and, putting it in motion, at the rate of 150 feet per minute, found that the spider would thus continue to afford an unbroken thread during from three to five minutes. The specimen of this silk which Mr Rolt presented to the society, was wound off from twenty-four spiders in about two hours. Its length was estimated at 18,000 feet; its color was white, and its lustre of metallic brilliancy, owing, probably, to its great

opacity. He did not attempt to combine two or more filaments into one winding, nor to form it into thread by throwing. The thread of the garden spider is so much finer than that of the silk-worm, that the united strength of five of the former is, according to Mr Rolt, equal to only one of the latter; and assuming that the weight is in proportion to the strength, and that a spider will yield twice a year a thread 750 feet in length, while that produced by a single silk-worm is 1900 feet, it follows that the produce of one silk-worm is equal to that of 63 spiders. Now, says the Report in the Society's Transactions, 'as on an average it takes about 3500 silk-worms to produce a pound of silk, it would take about 22,000 spiders to produce an equal quantity. Besides, spiders are not so easily confined as silk-worms, and whenever two come in contact a battle ensues, which ends in the destruction of the weaker one. Spiders kept for silk must therefore be each in separate dens or cells; and the apparatus contrived by Mr Rolt for this purpose, although very ingenious and well adapted to carry on a course of experiments with a hundred or two, would manifestly be wholly inapplicable to any purpose of commercial utility.'

"But a gentleman of Langueedoo went a great deal further than the English experimenter, for he established a manufacture of spider silk, and so far succeeded that he made gloves and stockings from the fibres of the web. The great impediment, however, to his complete success, was the implacable hostility of these insects to each other. Recamur placed 5000 in 50 different cells, and the larger destroyed the smaller, till only one or two were left in each cell. But there is a species of spider noticed by Dr Walsh in his travels in Brazil, to which this objection does not apply. Here the insect was not solitary but gregarious; and colonies of more than 100 occupied the same web. The doctor's account of it is as follows:—'Among the insects is an enormous spider, which I did not observe elsewhere. In passing through an opening between some trees, I felt my head entangled in some obstructions, and on withdrawing it my light straw hat remained behind. When I looked up, I saw it suspended in the air, entangled in the meshes of an immense cobweb, which was drawn like a veil of thick gauze across the opening, and was expanded from branch to branch of the opposite trees, as large as a sheet, ten or twelve feet in diameter. The whole of this space was covered with spiders of the same species (*aranea maculata*) but of different sizes; some of them, when their legs were expanded, forming a circle of six or seven inches in circumference. They were particularly distinguished by bright spots. The cords composing the web were of a glossy yellow, like the fibres of silk-worms, and equally strong. I wound off several on a card, and they extended to the length of three or four yards.' There is here a fair field for the Brazilian speculator. The spider's web, which, in single threads, could support a straw hat, must be much stronger and tougher than the frail tissues of our own country, and might certainly be manufactured into articles of wearing apparel, if a proper quantity of it could be obtained. As these gigantic spiders of Brazil are not eaters of their own species, large colonies of them might be maintained with ease, and we doubt not, advantage to the experimenter."

"Holloa, lend us your penknife?" "I can't—] haven't got any! Besides, I want to use it myself."

TRUTH.—Adhere always rigidly and undeviatingly to truth; but while you express what is true, express it in a pleasing manner. Truth is the picture, the manner is the frame that displays it to advantage. If a man blends his angry passions with his search after truth, become his superior by suppressing yours, and attend only to the justice and force of his reasoning. Truth, conveyed with austere and acrimonious language, seldom has a salutary effect, since we reject the truth, because we are prejudiced against the mode of communication. The heart must be won before the intellect can be informed. A man may betray the cause of truth by his unreasonable zeal, as he destroys its salutary effects by the acrimony of his manner. Whoever would be a successful instructor, must first become a mild and affectionate friend.

WONDERS OF CULTIVATION.—There is scarcely a vegetable which we now cultivate, that can be found to grow naturally. Buffon has stated that our wheat is a fictitious production, raised to its present condition by the art of agriculture. Rye, rice, barley, or even oats, are not to be found wild, that is to say, growing natural in any part of the earth, but have been altered by the industry of mankind from plants not now resembling them, even in such a degree as to enable us to recognize their relations. The acrid and disagreeable *opium graveolens*, has been transformed into delicious celery, and the *colocort*, a plant of scanty leaves, not weighing altogether half an ounce, has been improved into cabbage, whose leaves alone weigh many pounds, or into the cauliflower of considerable dimensions, being only the embryo of a few buds, which in their natural state would not have weighed as many grains. The potato again, whose introduction has added millions to our population, derives its origin from a small bitter root, which grows wild in Chili and Monte Video.

A few days ago, a butcher in this neighborhood, who has always been considered "wide awake," lost a shoulder of mutton: and having ascertained that it had been stolen by a dog belonging to a certain attorney, he lost no time in repairing to its owner, and accosted him as follows;—"Pray, sir, if a dog comes to my shop and runs away with a joint of meat, cannot I make the owner pay for it?" "Certainly," replied the attorney. "Then I will thank you for 3s. 9d., which is the price of a shoulder of mutton your pointer has just stolen from me." The lawyer paid the money, and the knight of the cleaver thanking him and wishing him good morning, was leaving the office; but the solicitor said, "Stay sir, I must trouble you for my fee. You came to consult me, I gave you my opinion, and the charge is 6s. 3d." The butcher looked exceedingly "sheepish," but instantly paid the amount, and returned home with the loss of his mutton, and an additional 2s. 11d.—*English paper.*

Footo advised a gentleman who desired to attend a masquerade ball in a new character, to "go sober."

THE NEW ENGLAND FARMER

Is published every Wednesday Evening, at \$3 per annum payable at the end of the year—but those who pay within sixty days from the time of subscribing are entitled to a reduction of 50 cents.

AGRICULTURAL.

From the Journal of the English Agricultural Society.

PRESENT STATE OF THE SCIENCE OF AGRICULTURE IN ENGLAND.

[Continued.]

There is another class, however, of manures that serves inquiry as much as any branch of agricultural practice, and which also seems to lend itself more readily to our experiments—those which are produced by animals upon the farm, whether in the yard, the stall, or the fold, but which are prepared by the farmer, either from the earth, lime, for instance, marl, peat ashes, gypsum, nitre; or, as a refuse of certain trades, such as bones, rape dust, salt dust, even woollen rags. The former of these may be called the mineral manures, are now perhaps in more limited use than in past times; still Devonshire and some midland counties, lime is regarded as indispensable, and is carried very long distances over bad roads at a heavy expense; but rick, which was once so highly valued, is in many tracts almost forgotten. Not so with the second class, which may be called the refuse manures: of these, bones in particular, form a new feature in husbandry, and their consumption is yearly increasing. In the year 1823 the declared value of the bones imported from foreign parts was but 2954; in 1832 it was 78,000; in 1835 it had reached 155,279; in the next year, 1836, it advanced to 171,806; and in the following year, the amount of which we have any account, it amounted to less a sum than 254,600. This is the declared value, which the real value greatly exceeds; and includes altogether, of course, the large quantity of this article which must be produced at home. In the present, bones are chiefly applied to the turnip crop, and on some soils their effect is certain and great. Yet no single instance can show the necessity and advantage of scientific inquiry more than the use of a manure. It is well known that bones contain a large portion of oil, which is usually extracted by boiling; and it might naturally be supposed, that the natural oil should at least be left in the bones, which are intended to be so applied; and farmers, accordingly, who purchase bones have explained that these had fraudulently been boiled. Contrary to expectation, there is reason to doubt whether the bones are not actually improved in manure by the loss of that oil, by which, if such be the truth, their own active principle, whatever it would appear to be denuded and sheathed. It is a point that may be easily tested; but there are larger questions connected with the use of these. They are, as is well known, an expensive manure, and their price is rising; but it is by no means known in what quantity they should be applied. At 10 bushels to the acre, however, if the price be 2s. per bushel, the outlay is already large, and only 20s., a sum probably exceeding the rent, and 20 bushels it will be 20s. or 260l. for a field of

100 acres. But as yet there is reason to doubt whether any increased quantity beyond 25 bushels of small bones produces any increased benefit to the crop; and no one will venture to assert that he knows the point beyond which an additional outlay is a mere loss of money and waste of a manure which is becoming daily more scarce. Again, as to the kind of soil on which bones may profitably be applied, there are some on which they have as utterly failed, as they have signally succeeded on others; but on this important point, as on the preceding, the valuable answers returned, chiefly by practical farmers, to the questions sent out by the Doncaster Agricultural Association, at the instance of Mr Childers, afford the only authentic data to which we can refer at present for guidance.

After the ground has been duly prepared, there is still ample room for inquiry and for improvement. On the best season of wheat sowing, for instance, there exists great difference of opinion amongst cultivators. Dr Mavor, in his 'General View of the Agriculture of Berkshire,' published no longer ago than the year 1813, states that, on the chalk hills of that county, wheat was sown as early as August. This year a practical farmer of that very district has given his opinion that it matters not how late wheat is sown, and that December is soon enough. The quantity, too, of grain to be sown is a matter of varying practice, and there are high authorities for thick sowing and for thin. Yet a saving of half a bushel of seed, if it can be properly made, will be a gain of 2s. per acre, or about one-sixth of the average rent of arable land to the renter, and of 240,000 quarters, or 600,000, to the country each year. Now, this question can obviously be solved, not by loose argument, or appeals to practice, which is always appealed to while and where each practice obtains, but by careful, extended observation continued through a variety of mild and hard winters, wet and dry springs and summers. As to the quality of seed to be sown, no one can doubt that such good may here be reasonably expected from increased attention.

That well known variety of barley the Chevalier, is an instance in point. The discoverer, Dr Chevallier, has obligingly sent the following account of its origin, in reply to an inquiry from our secretary:—"An extraordinary fine ear was observed and selected, by a laborer of mine, in the parish of Debenham, 1819; in the spring of 1820 I planted 27 grains in my garden; in 1825 I planted half an acre of this species, and half an acre of the common species; the land under precisely similar conditions of cultivation. The produce of the first amounted to 8 1/2 coombs; of the second, 6 1/2. The ears of the first averaged 34 grains; the second 30; the grains of the first heavier, as four to five. In the course of five or six years it was generally accepted and approved in my neighborhood, as I promoted its fair trial, and charged only the current market price for it."

It is not enough for the farmer to know the best management of an individual crop, even of all crops singly, unless he know also in what order of succession they should follow each other. It is by

improved knowledge of this order, and a better selection, that much improvement has already been effected in British agriculture. It is well known that crops of the same kind following each other become rapidly less productive; whether by exhausting the land of some fertile property, or by depositing, as has been lately supposed, some excrementitious matter injurious to the growth of their own species, though favorable, perhaps to the luxuriance of some other tribe. Be this as it may, no one would now think of growing, as formerly, wheat, barley, and oats in succession; and though Mr Hitchins, land surveyor, of Brighton, states that in his recollection, the tenants of a gentleman living in Sussex, when a clause was introduced into their leases prohibiting them from growing more than two white crops in succession, complained that they could not hope to defray their rents if fettered by such restrictions, few good farmers at present, on light soils at least, come even up to these limits by raising even two white crops, as they are called, in immediate succession. It is on these light lands, indeed, that a due rotation of crops has so signally succeeded, that, whereas they were formerly considered of very inferior value, they are now more readily occupied than those heavier soils, which, being in their nature, more suited to the growth of wheat, were once valued more highly. And it is as much by the slow and almost insensible amelioration of such land, as by any increased breadth of cultivation, that the country has become in any degree capable of supporting the vast numbers which have been added to her population. A small parish might be pointed out, in which an aged farmer remembers the time when a single rick was all that it could produce of wheat in one year; whereas, without any increase of its ploughed ground, that same parish now yields five or six yearly. Its sandy soil was then drifted like snow before the wind, and the scanty barley might be sometimes seen burne away also; whereas the very fields, still called "The Sands," are now, by that glutinous quality which high condition imparts—by the droppings and the tread of the sheep which are fed on the turnips that now grow in garden-like order where before was a naked fallow, compacted into a brown and adhesive, though still lighish loam. But though the Norfolk or alternate, or four course system of husbandry (so called because its simple rotation consists of turnips followed by barley, and clover by wheat,) has conferred such great though silent benefits on the country, it may be doubted whether that system has not accomplished all that it is capable of, and must not pass into another. Already it has begun to fail in one of its green crops, probably in the other. The red clover, it is admitted, can be no longer repeated once in four years, and the substitution of white clover, or of rye grass in the alternate fourth year, or the prolongation of the course to five years by sowing rye grass with the clover, and thus leaving the ground in grass for two years successively, are but imperfect remedies. The evil, however, is likely to increase; for in Flanders, whence the red clover was originally brought over, and where

the land has been longer tired with its repetition, it has been destroyed in whole districts by a grey parasitical plant called *orobanche*, and the only cure has been the entire suspension of its cultivation in those districts for many years. It is well known also, that in Norfolk, where the turnip has been longest cultivated, that root has become subject to a disease which distorts it with unhealthy excrescences; and it may be worth inquiry whether, apart from dry seasons and the depredations of insects, the late general failure of the turnip be not in some degree owing to its too frequent repetition.

Such being the ill results of a too scanty rotation, which consists in the endless repetition of four crops, the remedy must of course be sought in a greater diversity; and here we cannot but look to that neighboring country whence our green crops were first derived. In Flanders we find rotations of great richness and endless diversity, carried over a term not of four years, but of ten, eleven, and even fourteen. Into all of these potatoes enter, consumed on the farm, being in fact the chief food of the cattle during the latter part of winter and the beginning of spring. Carrots, too, are sown on the same ground with barley or peas, and after either grain is harvested, come also to maturity in the autumn of the same year. The barley harvest, however, is much earlier than in this country. But though our summers do not certainly encourage such double culture, peas might be early enough ripe even with us to admit of its trial; but at all events, the Flemish carrot, a white variety, may be worth cultivating as the crop of the year, since it is said to yield 22 tons by the acre, where the common orange or Dutch carrot gives but 11. Parsnips, it appears, are grown also where the soil is too heavy for carrots, and being extremely hardy, are left in the ground during winter, and drawn only as they are required for immediate use. They are thought not so good for milk cows as carrots, but superior for fattening cattle. We have long had another root, the mangel-wurtzel, which may serve, if grown on a part of the turnip field, to prevent the evils arising from the too frequent recurrence of that principal crop; and it is well known, if stored up, to come into useful service for ewes with their lambs in the spring. There is a mode which our own farmers have taken towards the doubling of crops, not indeed on one piece of ground at one time, but on one piece in the same year.—Between the wheat harvest in August and the sowing of turnips in June, there occurs in the four-course system a gap of nine months' idleness for the soil. This interval is filled up, on a part at least of the wheat stubbles, with a crop of rye to be fed off green in the early spring, at the time when fresh food is most wanted for stock, and least easy to be procured. So far as this extends we have thus two crops where our forefathers left a naked fallow; and it may be worth inquiry again how far this system can be extended. But this important subject of the rotation of crops, though much may be done by individual enterprise, requires such minute attention to so complicated results spread over so long periods, that it is only on an experimental farm we can hope to see it fully investigated.

It might be supposed that when these different stages of husbandry had been successfully passed, when the subsoil of a farm had been mellowed, or rather when it had been gradually blended with the soil, and the soil itself might thus be said to have been brought to a double depth, when the sur-

face of the field had been dressed with the most suitable manure, either natural dung, or artificial manure, whether of the mineral or refuse class, had been worked with the right implements, in the right manner, at the right time; sown with the most productive seed, and, above all, sown in the best course of rotation, when the crops thus prepared had been cleansed either by the hand or the horse-hoe (as in that, thus last, little known in the south of England, though long practiced and approved for the turnip crop in the north); but it might be supposed when the crops had been thus made ready, that nothing remained for the farmer but to await the fostering influence of the sky, the dropping rains and alternate sunshine, until after a joyful harvest, he should reap the reward of his toil at the neighboring mart. Little, however, does the sanguine calculator upon paper know of the farmer's real anxieties and frequent disappointments—of the blights, and rusts, and mildews; the insects and the fungi, which falling, as if in an unseen cloud, on his fields, impair, if not destroy the vegetative power which he has so carefully and expensively endeavored to nurture.

(To be continued.)

From the Albany Cultivator.

FARM WALL.

Common stone wall, for durability, and an effectual security to crops, is not surpassed by any other kind of fence. The making of it is somewhat expensive, but the benefit, resulting from removing a useless incumbrance from our farms, more than counterbalances the expense.

Although the advantages of this kind of fence are obvious, yet, with many, it is not in very high repute. They object, that it is every year falling down, and requires much labor to keep it in repair. This objection has some force from the fact that many of our walls in the western New York are unskillfully built.

The stones in this region are not generally of the best kind, and wall built of them will not stand as well as wall in those parts of the country where the material is more abundant and of better form. But I know from actual experiment, that wall built as it should be, will make a very permanent fence, and require but little repair.

Much of our wall in western New York is laid wrong side up, that is, the stones that are laid at the bottom should be laid at the top. The largest and best shaped stones are selected to be laid upon the ground, the next best for the second tier, and so on till the wall is topped out with small stones, unfit for the place. Although this, at first thought, might seem to be the best way of building, a little reflection and experience will teach a man that it is the very worst. Where will your round and cobble stones lie best? Is it not on the ground, where they will be firmly imbedded in earth, and must be immovable? And will not your large and well shaped stones make a much better superstructure than the small cobble stones?

In many parts of New England, wall-laying is a trade; and I have observed that they there select their poorest stones to lay upon the ground. They lay a broad foundation, and with small stones raise the wall from 8 to 12 inches high. This absorbs most of the poor stones. They then select stones a size larger, and lay them in a double row on each side of the wall, and thus raise their wall 12 or 15 inches. They then select their longest and

best stones, and lay them across the wall, so as to firmly bind together the two sides, reserving small or but good shaped stones for completing the top of the structure.

The wall, when thus built, should be secured by ploughing about three furrows on each side, and throwing up, with a shovel, the last furrow so as to raise an embankment against the wall, at least a foot high. By this means the small stones are all covered, and lying beneath the surface, will be but little affected by frost, and will lie as firm as the best stones you could select. Even if they were no larger than the stones used on a McAdamsized road, they would make a firmer and surer foundation than broad and flat stones. The small stones will settle about uniformly and equally into the earth, and being pressed by larger stones above, will lie steady and unmoved in their place. But when large stones are laid upon the ground, the heaving of the frost, and the softness of the earth in a wet season, will cause them to settle more on one side than on the other, and thus tumble down the cobble stone structure above them.

The method of building wall here recommended, will, I think, commend itself to the reflecting and intelligent. But if any have doubts, I could easily remove them by showing them wall that has stood the test of time, remaining firm in its place, while wall laid in a different manner has become dilapidated.

There is another error in wall laying that I would notice. Some take great pains to lay the smooth surfaces of the stones outward, so as to give a handsome face to the wall. To effect this, they often lay the stones in the most unfavorable position. I have often seen a long and smooth stone set up edgewise and lengthwise in a wall, which seldom fails to be crowded out by the pressure from above, to the ruin of the wall. But do the best you can, no great beauty can be given to a stone wall; and here, as in other cases, *utility* should not be sacrificed to *beauty*. That wall will eventually *look* best, that *lies* best.

In making wall, I direct to have every stone laid in a position so that it will lie most firmly in its own place, and bind together most effectually the stones beneath and about it, without regard to the beauty of the wall when completed. A.

Pittsford, Monroe Co., N. Y.

To make Leather Water-proof.—Melt a pound of tallow with half a pound of rosin. When melted and mixed, warm the boots or shoes, and apply the mixture hot with a painter's brush, until the sole and upper leathers will suck in no more. If it be desired that the boots should immediately take a polish, dissolve an ounce of bees wax in an ounce of spirits of turpentine, to which add a teaspoonful of lampblack. A day or two after the boots have been treated with the tallow and rosin, rub them over with the wax and turpentine, but not before the fire. Thus the exterior will have a coat of wax alone, and shines like a mirror. Tallow or any other grease rots the stitching and the leather—rosin gives it an antiseptic quality and preserves it.

Rhubarb.—This excellent plant, which should have a place in every garden, is very easily raised, requiring nothing more than a rich loamy situation. It is an orchard in miniature, the stems of its leaves affording a substance which is an excellent substitute for apples, to make sauce or pies. The sauce made from it is a preventive of bowel complaints.

EXCRETIONS OF PLANTS.

From observation, we learn that the matter excreted by plants is, as a general thing, thrown out in such a condition as to be, not only unfit again to enter the system of the plant rejecting it, but positively deleterious; and further, that the excretions of different plants differ so much from each other, that whilst that thrown out by a plant is deleterious to others of the same species, it is so sometimes well adapted to the nourishment of those of a different species. This fact will explain some of those rules which experience has taught the practical agriculturist. For instance, the rule that the same crop should not be grown for several years in succession upon the same piece of ground. It will not do to say, as is often done, that a second crop of wheat will not grow as well upon any given spot, as the first, because that spot has been exhausted of too great a portion of its nutritive matter by the first. This it is true is one reason, but if it be the only reason, or even the principal reason, we may ask, how is it that a crop of corn will succeed almost as well as if the wheat had never been grown there? The true explanation seems to be that the failure of the second crop of wheat arises not so much from the exhaustion of the soil, as from the existence in the soil of a portion of matter positively deleterious to wheat, deposited by the first crop; at the same time this matter is not injurious to the corn, and hence that crop will succeed when wheat would fail. To grow the same crop for several successive years upon the same spot, is, as De Caneolle has very pertinently, though perhaps not very elegantly remarked, "like feeding an animal upon its own excrements."

It is much to be desired that this matter should be made a subject of more careful and more accurate experiments than it ever has as yet, as it is one which would doubtless admit of very important practical applications. If the precise nature of the matter retained and of that rejected by each of the crops in common cultivation could once be ascertained, it would seem to be an easy matter to determine the best order in which those crops should succeed each other. Perhaps, too, if this subject was better understood, we should find that the way in which some manures benefit land, is not by supplying nourishment to the plants growing on it, but by removing this deleterious matter from their roots. If this matter possessed the character of an acid, and there are several facts which seem to render it almost certain that such is the character of the matter excreted by many plants) lime would act in this way—it would unite with the acid and neutralize its properties. The rotation of crops is a matter very generally attended to in farming, but in gardening, where it is of still greater importance, it is frequently neglected, and as a necessary consequence, garden plants degenerate under so injurious a system of cultivation. Our best gardeners have been taught by experience never to sow the same plant even for two years in succession, upon the same spot of ground.

When the root of a plant is cut off, and the stem placed in water, the excretions matter, which in other circumstances would have been discharged from the roots, issues from the end of the stem. Hence it is that water in which flowers have been kept for some time, always becomes offensive. We commonly say that the water has become putrid; but pure water can never become putrid; the offensive character of the water in such circumstances

arises entirely from the rejected matter excreted by the stem.

It is a fact, which I suppose all must have noticed, that some plants when placed in water together, seem to keep each other alive, whilst others produce just the opposite effect. This is owing to the nature of the matter excreted by their stems. Where the matter rejected by one plant is of such a nature as to be suited to the nourishment of the other, they will keep each other alive; but where the opposite is the case they will hasten each others death. In the same way we explain the fact that a nosegay composed of many different flowers, will, when placed in water, generally preserve its freshness much longer than one composed of the same number of flowers of the same species. There is a class of plants commonly called weeds, which cannot grow in the immediate neighborhood of our common cultivated plants without materially injuring them. This is doubtless in part owing to their containing the nutritive matter contained by the soil, and in part also to their overshadowing the cultivated plant and thus shutting it out from the direct action of the sun, but it is also, in part, owing to the nature of the matter which they deposit in the soil. The common opinion that weeds poison the plants in whose immediate neighborhood they grow, is not mere imagination—it is nothing more than a simple statement of the facts of the case.

It is a curious fact, frequently noticed by botanists, that plants in their wild state, grow in natural groups. This is in part to be attributed to the varying nature of the soil—such plants as prefer a sandy soil, being collected together where such a soil occurs; and in part also to the operation of the matter deposited by them in the soil. Such plants as deposit matter of a nature fitted to sustain and assist each others growth, will generally be found growing together. It would seem, that in parceling out the earth, the Creator has not assigned particular species of animals alone to particular portions, and given them the means of defending themselves against the aggression of their neighbors; but that he had taken the same kind of care for plants, at least to a certain extent. If a seed of a plant which properly belongs to one portion, is by accident thrown upon another, the plants to which that portion belongs, soon destroy it. Thus has the Creator fixed for every separate portion of creation, "the bounds of its habitation."—*Farmers' Register.*

Exhausted Lands too soon Abandoned.—The fault of the farmers upon our hard soil has been to abandon the ground after the skinning process. This was natural while other fertile lands remained in the vicinity to be cleared that would produce larger crops. And now a farmer that has mowed over forty, fifty and a hundred acres year after year until he has reduced the crop of hay down from two tons to one ton, half a ton and even four or five hundred pounds to the acre, is as a matter of necessity willing almost to give away the ground that yields so scantily, to seek a livelihood by taking women boarders at the price of a dollar or a dollar and a quarter a week, near some great factory establishment, or else to pack up "bag and baggage" and set out for the land of promise in the west.

To men so discouraged as these have been in times past, I believe the alternative offers of a much more certain chance of success in life; and that is, in the renovation of worn out farms. If a man is in debt to the amount of its whole value, he

had better purchase a portion of what was his own on credit, and remain upon it, than abandon it.—With common health, with a good resolution and good habits, he may as soon lay a foundation for the future sustenance and comfort of himself and family as he can perhaps any where else. The poorest places for steady employment, I am induced to believe, are our largest towns and villages. Among the farmers the poor man can almost everywhere be employed at a price either in money or produce to help sustain his family; his wife and children who are of sufficient age can also find some kind of business where industry shall aid the exertions of the father; nay, is it not an event of frequent occurrence that females in a family alone earn its support? The poor man can work for others as well as on the ground which he has purchased or hired. But let him work it right at home. If he have but a single acre of the worn out land—I do not mean impervious rock or that gravel or sand on which labor and manure will have no effect, but that retentive soil which holds manure, or such barren wet soil as may be drained—or such impoverished soil as requires the plough or the iron bar to strike deeper than it has been wont; if he begin with an acre of such land and begins aright, the first year will give him better pay for the labor and application than he ever obtained under the skinning process; the product will be increased in a compound ratio in succeeding years; and in a few revolving seasons he will find his single acre yielding him more clear gain than some farmers obtain from fifty and a hundred acres, under the wearing-out mode of cultivation.—*Gov. Hill's Address.*

Night Soil.—Mr Robinson, of Baldwinville, inquires "by what process night soil can be converted into an inodorous manure in a short time, so that any cultivator may be able at once to remove a nuisance and obtain a valuable manure." We are unable to inform Mr Robinson of the processes adopted where the preparation of poudrrette is carried on extensively and in the most approved manner; but it is said in the 1st vol. British Husbandry, that "All unpleasantness of odor may be prevented by the mere use of ashes; and were those thrown upon the night soil or into privies that have no communication with sewers, the ashes made in every dwelling house would so completely absorb the fluid parts, that a solid heap of manure would be produced, which might afterwards be removed without difficulty or offensiveness." This is the method practiced extensively in some parts of England, and on the continent. Lime is, however, much better than ashes, and this is the disinfecting agent wherever poudrrette is produced. In Rigby's Agricultural Reports, the following is recommended as the best method of preparing and using night soil: "Spread it on a spot of clean grass: let it be well harrowed on a clear drying day; then put it under cover, and add a chaldron of lime to four loads of the soil in that state, and it will become dry, and can be reduced to an inodorous powder." All that seems to be required, is to mingle with the drained material something that will dry and render the mass friable and pulverulent. Lime is the most efficient agent for this purpose, and that which is slaked, is stated in Pilkington's Transactions to be preferable for this purpose to that which is caustic.—*Many Cultivator.*

That excellent paper the Genesee Farmer, has been united with the Albany Cultivator.

THE GOOD WORK ADVANCING.

Nothing can have a greater tendency to encourage the friends of an enlightened and judicious system of agriculture to persevere in their praiseworthy efforts, than the spirit of improvement which appears to be widely diffusing itself throughout our land. The results of the late Cattle Shows and Agricultural Exhibitions held in various parts of the Union during the present season—the increasing interest manifested by members and others—the fine condition of the stock exhibited—the great variety and value of new agricultural implements, and the determination of the tillers of the soil not to rest short of every attainable improvement to bring their farms to the highest grade in the scale of fertility, and of consequent profit to themselves, and great advantage to the community at large—are full of promise.

During the present year a large number of Agricultural Societies have been organized, possessing within themselves the elements of great good. Besides, several societies formed long since, and which were permitted to languish through the lukewarmness of their members, have been re-suscitated—many new societies have been formed, numbering among their members many of the most enlightened and public spirited agriculturists of our country—and far greater attention has been paid to the interests of agriculture in all its various departments, than at any previous time. Experiments have been made, if not on the great scale, at least very extensively—and in this matter the farmer has a decided advantage. Knowledge has been greatly increased, and our brother farmers, many of them at least, are prepared to enter in good spirits and in somewhat improved circumstances, on the labors of another year.

The raising of roots for the purpose of feeding cattle is no longer a matter of experiment. The great importance of this crop is now established, and we presume that those persons who have put in their winter grain, where the sugar beet has been last raised, and especially if two successive crops have been taken from the same ground, provided the earth has been properly turned up, and the grain sown of a good quality, will be abundantly satisfied with the results of the ensuing season.—The sugar beet especially, and the root crop in general, has a tendency to leave the ground in admirable order for any of the small grain crops to succeed. While we recommend to every farmer to put in a full supply of roots the ensuing season, sufficient for his cattle during the next winter, we would advise him not to entertain the opinion, or even to attempt the manufacture of sugar from the beet. It is not the province of the farmer—and in the present state of chemical and agricultural science, it cannot become a profitable subject of household fabrication. To be successful, its manufacture must be conducted on the great scale, then there is neither risk nor difficulty. The farmer should be content with raising, at the present, a sufficient quantity of roots for his own use, and the keep of his stock, and when sugar manufactories and refineries are established, then it will be time to think of raising beets for the purpose of sugar-making; and no doubt, if the business is properly commenced—with a competent head, sufficient capital, and the right kind of machinery—a ready market at fair prices will be found for all the beets that can be raised within the proper circle of each manufacturing establishment. But, admitting that a pound

of sugar is never made from the beet, still, its introduction into the country, and its almost universal culture, must be regarded as a national benefit. The large return it renders, the eagerness with which almost all kinds of stocks feed on it, and their disposition to fatten on it—its peculiar adaptations to dairy stock, not merely increasing the quantity but also the quality of the milk and butter, together with the excellent order in which it leaves the ground on which it is grown, all concur in pointing it out as one of the most eligible crops the farmer can raise. We would by no means have the sugar beet raised to the exclusion of other root crops, especially such as the ruta baga, carrot, potato, &c.; as a change, even for stock, is both good and desirable.

The more general introduction among our farmers of improved implements in agriculture, has not been without its effect. Many of these machines are calculated not only to lessen the labors of the field, but also perform the work in a more perfect manner than it can be done by hand.

The stigma so long attached to this, the most noble of all earthly pursuits, is washed away—the strong prejudices have been dissipated, and agriculture is now regarded by the truly intelligent, as not only the first of arts, but the most dignified calling that can claim the attention of men.—*Farmer's Cabinet.*

CHOICE OF A PROFESSION.

It has frequently occurred to us that our young men, on completing their studies in our colleges, mistake the road to usefulness and comfort in preferring the study of some fashionable profession to the pursuits and occupations of rural life. As soon as a young gentleman is admitted to the degree of Bachelor of Arts, his thoughts are turned on the future, and perhaps the first resting place they find is upon the acquirement of professional knowledge of some kind, which to him seems the only road to wealth or distinction. Thus we see the science of agriculture neglected by those who are capable of investigating it as it should be; and every possible inducement to engage in the improvement of the soil, and to assist nature in what she is wont to do for man is but a feather in the scale of reasoning. And through fear of adopting some pursuit that is attended with a little labor, and, as some call it, drudgery—but which is the greatest conducive to good health—resort is had to the study of some profession—which has done, and we fear is doing great injury to our country. We wage no war against professions of any kind; on the contrary, they are indispensable, but it is a fact that it is considered an unpopular step nowadays for a young man on completing his academic studies, to devote his time and talents, if he possesses any, to the advancement of the cause of agriculture.

We have before us an address, delivered before the young gentlemen admitted to the degree of Bachelor of Arts, at the first commencement of the University of Nashville, by its venerable President, Dr Philip Lindsey—which deserves to be more extensively circulated than we fear it has been—and from which we make the following extract.—*Southern Cultivator.*

"I know not what are to be your future professions or occupations. Every honest calling ought to be esteemed honorable. I address you as moral and intellectual beings—as the patriot citizens of a great republic. You may be merchants, mechanics, farmers, manufacturers—and yet be emi-

nantly distinguished and eminently useful, if you will persevere in seeking after knowledge and making a proper use of it. The Medici—Necker—Ricardo—were merchants or bankers; Franklin was a mechanic; Washington was a farmer. By far the greater part of our countrymen are and must be farmers. They must be educated; or what is the same thing, educated men must become farmers, if they would maintain their just influence and ascendancy in the State. I cannot wish for the alumni of Cumberland College a more healthful, independent, useful, virtuous, honorable, patriotic employment, than that of agriculture. Nor is there any condition in life more favorable to the calm pursuits of science, philosophy and religion; and to all that previous training which ultimately constitutes wisdom and inflexible integrity. Should our college eventually become the grand nursery of intelligent, virtuous farmers, I shall esteem it the most highly favored institution in our country. I have long thought that our college graduates often mistake the true path to honor and usefulness, in making choice of a learned profession, instead of converting agriculture into a learned profession, as it ought to be, and thereby obtaining an honest livelihood in the tranquil shades of the country."

A HINT.—A soil may be forced, by extreme care, enormous expense, and the use of manure without measure, to produce all sorts of crops; but it is not in such sort of proceedings that the science of agriculture consists. Agriculture ought not to be considered as an object of luxury, and whenever the produce of agricultural management does not amply repay the care and expense bestowed upon it, the system followed is bad. A good agriculturist will, in the first place, make himself acquainted with the nature of the soil, in order to know the kind of plants to which it is best adapted. This knowledge may be easily acquired by an acquaintance with the species of the plants produced upon it spontaneously, or by experiments made upon the land, or upon analogous soils in the neighborhood.—*Farmer's Cabinet.*

THE FARMERS.—The following just and eloquent tribute to this meritorious class of American citizens, is from the pen of an eminent New England clergyman.—*ibid.*

"There is one class of men upon whom we can yet rely. It is the same class that stood on the little green at Lexington—that gathered on the heights of Bunker Hill, and poured down from the hills of New England—which were the life-blood of the nation when the English lion was ready to devour it,—I mean the FARMERS. They were never found to trample on law and right. Were I to commit my character to any class of men, my family, and my country's safety, it would be to the farmers. They are a class of men such as the world never saw for honesty, intelligence and Roman virtue, sweetened by the Gospel of God. And when this nation quakes, they and their sons are those that will stand as the sheet anchor of our liberties, and hold the ship at her moorings till she outrides the storm."

Agriculture is the theme of the day. The most enlightened of our citizens are embarking in its pursuits, which give assurances of its being ultimately established on a basis concomitant with its merits.

For the New England Farmer.

BERKSHIRE PIGS.

"Be Gar! Monsieur Tonson come again!"

MR. EDITOR.—Some time in November last I received through the post office a number of the "Boston Cultivator," containing a communication from M. S. Turner, which I presume he intended as a reply to mine in the New England Farmer of Oct. 14. As his name was written on the margin, I did every reason to believe he intended it as a knock-down argument, and I must forever after bid my peace.

I immediately addressed a communication on the subject to the Editor of the "Boston Cultivator," which, for reasons best known to himself, he has published.

The communication of Mr. Turner, referred to above, I also find in your paper of Nov. 20th, and could I let it pass unnoticed, some might consider conclusive.

Now, sir, I assert that there is deception on the very face of it—for there is no such firm as "Bement & Glauson," nor is there any such person as uson residing in Albany. He says—"But to have they were procured of them, I send you my cher, which is a bill of sale signed by Thomas Reed, jr., and is in the following words:—'Fragham, June 13th, 1830.—I hereby certify that I sold this day to Mr Wm. Turner, 14 loaded Berkshire pigs, which I had of [O, tempora! mores! where is his conscience?] Messrs Bement & Glauson, of Albany, N. Y., and from their recommendations. Thomas Reed, Jr.'"

This certificate appears to be Mr. Turner's sheet nor—his proof positive. He also says I did not do that they were procured from Bement & Glauson. I said, "as regards myself, I deny in toto, of never ever sold any Berkshire pigs to Wm. S. Turner, or any other person in that town." I did of course, include the name of Thomas Reed, jr., did not then know there was such a man in existence.

To make my story short—Not long after I read the Boston Cultivator, I met in Albany, Jeremiah Miller, a farmer, who resides in the town of Mack, six miles east of Albany, who keeps a Berkshire hogs and some Durham cattle. I led him the substance of Mr. Turner's advertisement, certificate, &c. "Why," said he, I sold the 14 pigs, and they were only seven-eighths Berkshire, and I sold them to him as such. He led me to give him a certificate that they were loaded Berkshire, which I refused to do. He concluded it would be better not to have my certificate. [I presume he thought one from Bement & Glauson would answer better.] "I sold at the same time," continued Mr. Miller, "one loaded Berkshire pig and gave him a certificate at effect."

As above, Mr. Editor, is the history of the "14 Berkshire pigs," as advertised by Wm. S. Turner, backed by a certificate from Thomas Reed, jr., which being procured of "Bement & Glauson," further comment is needless.

Respectfully, your obed't serv't,

CALEB N. BEMENT.

see Hill's Farm. Jan. 1st, 1840.

MAMMOTH PEAR.

This pear was raised in Virginia and given to Mr. Fitch, of Danville, by his friend, Dr. Green of the same place, as a sort of Christmas or New Year's present and served up in the family of Dr. Ball, of Northboro, and passed about to the guests as a part of the evening's entertainment—a portion of which was presented to us by Dr. Barnard, of Dorchester, who had the high gratification of carving it up for the company. We have had the pleasure of witnessing a longitudinal survey of the fruit, and are thereby enabled to testify to the dimensions which were given and proved to be as follows: longitudinal circumference 15.1-4 inches; transverse or horizontal circumference 13.1-4 inches; the weight of the pear was 1.3-4 of a pound.

It is but just to say that the pear probably neither weighed nor measured so much as when taken from the tree. It had shrunk some and was considerably defective in the flavor, however, was not impaired, and we found it very palatable.—*Com.*

CHANGE IN SOIL EFFECTING A CHANGE IN PLANTS.

A change in soil may be effected either by removing a plant from one spot of earth to another differing from it in fertility, or by the addition of manure, producing a change in the character of the soil in which a plant grows, without changing the location of the plant. The effect of removing a plant from a comparatively barren to a more fertile soil, is to increase the size of all its parts, and often to convert its organs of one kind into those of another. Experience has taught us, that it is advantageous to supply food to plants artificially. Where increase in the size of vegetables, without reference to their magnitude is desired, it can almost always be accomplished, by affording an increased supply of all the ingredients of the food of plants, distributed in well pulverized soil, in such a manner that the roots of the plants can easily reach it. The effect thus produced, can be greatly increased by additional heat and moisture; and by a partial exclusion of the direct rays of the sun, so as to moderate the evaporation of fluids from the plant. Experience alone can determine to what extent this may profitably be carried in the case of each species of vegetable. The results which have been produced in some instances are truly remarkable. Loudon states that cabbages have been produced weighing half a hundred weight, apples a pound and a half, and cabbage-roses of four inches in diameter, or more than a foot in circumference. By cultivation and a change of soil, the appearance of many trees has been entirely altered. The wild crab apple, the original stock from which all our vast variety of apples have sprung, has its stem and branches thick set with thorns. On removing it to a more fertile soil and more favorable circumstances, all these thorns have disappeared, and their place has been supplied by fruit-bearing branches. Yet all the distinctive characteristics of the tree, the structure of its wood and bark, the shape and arrangement of its leaves, the form and aggregation of its flowers, indeed all that a botanist would consider characteristic of the plant, have remained unchanged.

Perhaps the most remarkable changes which result from a change of soil, are those of organs of one kind into those of another. It is by such changes that all our double flowers have been obtained. The organs which are most commonly converted

into others, are the stamens, and next to them the pistils. In the hundred-leaved rose, and some other double roses, almost all the stamens have been converted into petals; in the flowering cherry the pistils have been converted into green leaves; in the double columbine a part of the stamens have been converted into petals, another part into nectaries, whilst a third part have retained their original form. The perfect regularity with which the changes have taken place in the last mentioned flower is worthy of notice. Wherever one stamen has been converted into a petal, a corresponding one has always been converted into a nectary; and so regularly have these changes proceeded, that by careful dissection, you may separate one of these double flowers into several single ones, each perfect in itself, and destitute of none of its appropriate parts. Where flowers have been doubled by art, the only sure way of propagating them, is by some means by which the new plant should be nothing more than a continuation of the old one, as by slips or cuttings. Whenever the seed is resorted to, there is danger that the plant will revert to its original type, and the flowers appear single again. A change of color also frequently results from a change of soil. Respecting the nature of this change, no fixed laws have been as yet discovered. As a general thing, however, the brightness of the colors of a flower is injured by enriching the soil in which it grows; and hence florists, when they wish to procure tulips of very bright colors, prefer planting the bulbs in a light sandy soil, which is rather poor than otherwise.—*Farmers' Register.*

Agricultural Improvement.—In the retrospect of the past, we will find that agriculture has received a greater impulse during the last twenty years than in double or treble that period, previously,—that during this space of time, scientific knowledge and enlightened education have been brought to bear upon the subject, and in putting theory into practice, the narrow prejudices contracted by the world at large, have been thrown aside. Science has clearly demonstrated that in this pursuit there is an ample field for the exercise of the clearest faculties, and the deepest scientific researches, calculated to afford enjoyment to those engaged in it, and fully reimburse their expenditures.

This march of improvement is not stayed,—happily we may safely assert, that at no point of time was it more in the full tide of progress than at the present, and no limits can be set to its advancement. To quicken it, our farmers themselves must lay hold of the matter;—they should individually feel that a portion of this work is assigned them;—that they are called upon as integral parts of a great community, to further its interests, by the means which they severally have at command;—they should be willing, impartially, and unbiassed by old prejudices, to canvass all their actions, and bring them to the test of reason. They should not suppose that in any one particular have they reached to ultimate perfection, but keep this always in view as the point to arrive at.—*The Mer & Cub.*

Notwithstanding the immense grain crops of this country the past season, and the fact that large quantities of flour have been exported to Europe, still several vessels have arrived at New York lately, with rye from Odessa. This may seem somewhat strange to those who are not acquainted with the fact that this rye is intended for the distillery.—*Daily Times.*

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JANUARY 15, 1840.

AGRICULTURAL MEETING.

The Commissioner of Agricultural Survey having obtained the use of the Representatives Hall, for the purpose; notified the first agricultural meeting of the season, for Monday evening at 7 o'clock. The meeting was very fully attended. This evening was taken because no other evening in the week would have been convenient for Mr Webster's attendance, though it was sincerely regretted that it should interfere with other lectures held on that evening; and that, on this account the presence of many gentlemen, ardent friends of agricultural improvement, was prevented. Mr Webster, having, in his recent tour, made the husbandry of England a particular subject of observation and inquiry, it was highly desirable to have from his own lips some account of his observations and impressions; and of his views of the applicableness of foreign rules, and modes of husbandry to our own country.

The meeting was organized by the choice of Hon. Mr Thaxter, of the council, to preside; and the Agriculture of Massachusetts having been announced as the subject of the evening's discussion, intending by it to open a wide range of conversation, some general views of the subject and the leading topics of inquiry were briefly stated, when Mr Webster, being particularly referred to, rose and addressed the meeting in a plain, direct, perspicuous, instructive and admirable manner; and was followed by Professor Silliman, of Connecticut, likewise called upon by the chair, with a corresponding felicity of matter and manner.

It would be matter of the highest utility and gratification if both these addresses could be given in full by themselves. We can scarcely hope for this; and in place of it, as we know the public curiosity will be anxiously alive to receive them, we shall give, from a few very imperfect and hasty notes, our reminiscences of the principal remarks of these two distinguished gentlemen.

Mr Webster began with stating that he regarded agriculture as the leading interest of society; and in all its relations having a direct and intimate bearing upon human comfort and the national prosperity. He had been familiar with its operations in his youth; and he had always looked upon the subject with a lively and deep interest. He did not regard himself as particularly qualified to judge of the subject in all its various aspects and departments; and he neither himself regarded, nor would he have others regard his opinions as authoritative; but the subject had been one of careful observation to him, both in public and private life; and his visit to Europe, at a season of the year particularly favorable for this purpose, had given him the opportunity of seeing their improved husbandry, and as far as it might be interesting or would have a bearing upon the subject of the evening's discussion, the agriculture of Massachusetts, he would proceed to give his views and impressions.

How far in this matter the example of other countries was to be followed was a subject worthy of much consideration. The example of a foreign country might be too closely followed. It would furnish a safe rule of imitation only as far as the circumstances of a country correspond with those of the country whose rules and customs it was proposed to adopt.

The great objects of agriculture and the great agricul-

tural products of different countries were much the same. Bread, meat and clothing constituted these objects. Cotton might be regarded as an incidental product, peculiar to certain latitudes and countries. Though the great agricultural products of different countries were the same, yet there were various diversities of condition and circumstances, which materially affected the agriculture of different countries.

The primary elements which entered into the consideration of the agriculture of a country were four; climate, soil, price of land and price of labor. In any comparison, therefore of the agriculture of England with that of Massachusetts, these elements were to be taken particularly into view.

The climate of England differed essentially from that of this country. They were on the western side of the eastern, and we on the eastern side of the western continent. The climate of each country was materially affected by their respective situations in relation to the ocean. The winds which prevail both in this country and in England are from the west, and westerly winds blow three days out of four. These facts are familiar. The consequences resulting from them are, that our winters are colder and our summers much hotter than in England. Our latitude was about that of Porto, yet the temperature was very different. On these accounts, therefore, the maturing of the crops in England and the power of using these crops would create a material difference between their agriculture and ours. It may be supposed that our climate must resemble that of China in the same latitudes; and this fact may have an essential bearing upon that branch of agriculture which it is proposed to introduce among us, the production of silk.

The second point of difference between the two countries lies in the soil. The soil of England is mainly argillaceous; a soft and unctuous loam upon a substratum of clay. This may be considered as the predominant characteristic in the parts which he visited. The southern parts of England are sandy, resting upon deep beds of chalk. The rocks in England are of a different formation from ours. Ours is a granite soil. There is granite in Great Britain; but this species of soil prevails in Scotland, a part of the country which more resembles our own. Our soils are stony. Such lands are not found in England. We may have lands as good as any in England. Our alluvial soils on Connecticut river and in some other parts of the country, are equal to any lands; but these have no clay. It is not proper to compare the soil of England with the soil of America, because of the extreme differences in different parts of our country, stretching as it does through so many degrees of latitude, and embracing in its extent every variety of climate and soil.

The price of land, another important element in agricultural calculations, differs greatly from the price of land with us. It is three times as high as in Massachusetts.

The price of labor is much more in Massachusetts than in England. In different parts of England the price of labor is considerably various; but it may be set down as twice as dear with us as there.

There are several reasons which have suggested themselves in regard to the state of things there. Now have we anything to learn from them? Is there any thing in their condition applicable to ours; in which the agriculture of England may be of use to Massachusetts and to other countries?

The subject of agriculture in England has strongly attracted the attention and inquiries of men of science. They have studied particularly the nature of the soil. More than twenty years ago, Sir Humphrey Davy undertook to treat the subject of the application of chemical knowledge to agriculture in the chemical analysis of soils and manures. The same attention has been continued to the subject, and the extraordinary discoveries and advances in chemical science, since his time, are likely to operate greatly to the advantage of agriculture. The best results may be expected from it. These inquiries are now prosecuted in France with great industry and success. We may hope for like beneficial results here from the application of science to this subject with us.

A second material feature in the agriculture of England consists in the rotation of crops. It is a settled principle in their agriculture, that two white crops shall not come in immediate succession. A tenant would be discharged by his landlord who should violate this rule. White crops are grain crops, wheat, barley, rye and oats. These are succeeded by, or alternated with,

potatoes, vetches or tares, beans, peas, turnips and clover, which are considered as green crops.

The great improvements in English husbandry are traced to the introduction from sixty to eighty years ago of the cultivation of turnips. Before that time, the lands became exhausted by the repetition of grain crops there were left, as it was termed, fallow, that is, were not cultivated at all, but abandoned to recruit themselves they might. This occurred as often as every fourth year, so that one-quarter of the mable land was always out of cultivation and yielded nothing. Turnips are now substituted in the place of these naked fallows; and now land in turnips is considered as fallow. What is the philosophy of this? The raising of crops does not in itself enrich, but exhausts the land. The exhaustion of the land, however, as experience and observation fully demonstrated, takes place mainly when the seed of a plant are allowed to perfect themselves. The turnip crop is a biennial plant. It does not perfect its seeds before it is consumed. There is another circumstance in respect to the turnip plant, which deserves consideration. Plants, it is well understood, derive large portion of their nutriment from the air. The leaves of plants are their lungs. The leaves of turnips expose a wide surface to the atmosphere, and derive therefore, much of their subsistence and nutriment. The broad leaves of the turnips likewise shade the ground preserve its moisture, and prevent, in some measure, exhaustion by the sun and air.

The turnips have a farther, and ultimate use. Meats and clothing come from animals. The more animals are sustained upon a farm, the more meat and the more clothing. These things bear, of course, a proportion the numbers of bullocks, sheep, swine and poultry which are maintained. The great inquiry then is, what kind of crops will least exhaust the land in their cultivation and furnish support to the largest number of animals?

A very large amount of land in England is cultivated in turnips. Fields of turnips of three, four, a even five hundred acres are not uncommon. Sir the introduction of the turnip culture bullocks and she have trebled in number. Turnips, for the reasons given are not great exhausters of the soil; and they furnish abundant food for animals. Where one bushel of corn produced ten bushels of turnips may be grown the same cost.

The great difference in the two crops is to be found in the quantity of barn yard manure of their comparative value. This is the secret of great advantages, which follow from their cultivation. The value of manure in agriculture is well appreciated. Dr Ure states the extraordinary fact, that value of the manure annually applied to the crops in England, at current prices, surpasses in value the amount of their foreign commerce. There is no doubt that it greatly exceeds it. The turnip crop returns a vast amount of nutritive matter to the soil. The farmer t from his green crops, and by a regular system of rotation, finds green feed for his cattle and wheat for market. The growth of green crops is intimately connected with a system of rotation of crops.

The lands in the county of Norfolk, in England, sandy. Here is the place of the remarkable cultivat and distinguished improvements of Mr Coke, now L. Leveson. His usual rotation is barley, clover, turnip wheat. These lands resemble much of the land in the county of Plymouth; and the sandy lands to be found in the vicinity of the Connecticut and Merrimack river. The cultivation of green crops in New England, deserves attention. There is no incapacity in our soil; and no circumstances unfavorable to their production. What we be the best kind of succulent vegetables to be cultivated whether turnips, or carrots, or Swedes be was not proper to say. But no attempts within his knowledge had been made among us of a systematic agriculture and until we enter upon some regular rotation of crops and our husbandry become more systematic, no distinguished success could be looked for. As to our soil had been remarked, there was no inherent incapacity for the production of any of the common crops.

could raise wheat in Massachusetts. The average crop in England is twenty-six bushels to the acre. From our own farm, and it was comparatively a thin and poor soil, he had obtained this summer seventy-six bushels of wheat upon three acres of land. It was not there any want of capability in the soil; but the improvement and success of our husbandry must depend upon a succession of crops adapted to the circumstances of our soil, climate, and peculiar condition.

He has increased the rental of his farms by his improvements more than four times, from twenty-two hundred thousand dollars a year.

In England a large portion of the turnip crop is covered on the land where it grows. The sheep are fed doors all winter; and he saw many large flocks, thousands and millions of sheep, which were never shed. This was matter of surprise especially considering the wetness of the climate; and those sheep were exposed in fields where a dry spot could not be found them to lie down upon. Sheep were often folded in land by watted fences or hurdles temporarily erected in different parts of the field and removed from place to place as the portions of the crop were consumed. In cases they were folded and the turnips dug and fed to them. In such case they were always fed lands which were intended the next year to be left under cultivation. In one case he saw a man employed in the field in raising turnips with a crow bar grip, who was expected to be occupied exclusively business the whole winter. It is deemed by many as much the preferable mode to dig all the turnips sheep as they are wanted. In this case they are completely consumed. The Swedish turnip does not suffer even by being frozen in the winter, but is often thawed in the spring uninjured. In the of England turnips are generally housed; or they covered with straw on the land which is to be brought the plough. Land is often designated by way of example, as "land that will carry sheep;" that is, land on crops of turnips are raised for feeding the sheep; and such lands are greatly enriched by their being fed in. In the Lothians of Scotland, where the culture is as fine as in any part of Great Britain, turnips are largely cultivated. Here they are generally covered over. The Swedish turnips are particularly suited to a cold climate.

limits and the necessity of going immediately to not permit us to complete our report of the remaining. Mr. Webster's speech, which we regret to divide, together with the remarks of Professor Sullivan, shall give place to in our next. We feel that great injustice to Mr. Webster by our mode of reporting. We do not presume to give his words; and all consider ourselves quite fortunate, if we are useful in embodying and communicating with tolerable accuracy the information and sentiments uttered

MARKET.—MONDAY, JAN. 13, 1840.

Reported for the New England Farmer
Market 500 Beef Cattle, 130 Stores, 1050 Sheep, Swine.
Cattle.—We quote to correspond with the market. First quality, \$6 25. Second quality, \$5 50. Third quality, \$4 50 a \$5 00.
Sheep.—Mess \$5 50; No. 1 \$5 00.
Pork.—Very few sales effective.
Hams and Cakes.—We noticed a few sales at \$27, \$25, and \$40.
Lots were sold at \$2 25, \$2 75, \$3 50, and \$4 50.
Those at market were peddled from 4 to 6

THERMOMETRICAL.

Reported for the New England Farmer.
of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded exposure, week ending January 12.

A MAN WANTED.

work on a small place, a few miles from the city, and must understand the cultivation of vegetables, and the care of horse, cows, &c. A single man, of 30 years of age, of steady and industrious habits, will be at this office.
J. B. I.

ROIAN POTATOES.

at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at \$5 per barrel.
JOSEPH BRECK & CO.

VEGETABLE CUTTER.

Willis's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and excellent root for fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public; they are aware that it has been long wanted and they now offer a machine that cannot fail to give satisfaction upon a fair trial. It will cut with ease from one to two bushels per minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at the Agricultural Warehouse, 51 and 52 North Market Street.
December 18, JOSEPH BRECK & CO.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO at the New England Agricultural Warehouse and Seed Store, Nos. 51 and 52 North Market Street, have for sale, Green's Patent Straw, Hay and Stalk Cutter, operating on a mechanical principle not before applied to any implement for this purpose. The most prominent effects of this application, and some of the consequent peculiarities of the machine are:
1. So great a reduction of the quantum of power requisite to use it, that the strength of a half grown boy is sufficient to work it very efficiently.
2. With even this moderate power, it easily cuts two bushels a minute, which is full twice as fast as has been claimed by any other machine even when worked by horse or steam power.
3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.
4. The machine is simple in its construction, made and put together very strongly. It is therefore not so liable as the complicated machines in general use to get out of order.

BOSE MANURE.

The subscriber informs his friends and the public, that, after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.
He keeps constantly on hand a supply of Ground Bone, and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and no charge for casks or carting.
Also, ground Oyster Shells.
Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.
NATHAN WARD.

AMERICAN SWINE BREEDER.

Just published and for sale by JOSEPH BRECK & CO. the American Swine Breeder; a Practical Treatise on the Selection, Rearing, and Fattening of Swine, by Henry W. Ellsworth, price 75 cents.
January 15.

MISCELLANEOUS.

JOHN ADAMS AND GEORGE III.

The account that Mr Adams gave in a letter to a friend, of his introduction to George III. at the Court of St. James, as the first Minister from the rebel colonies, is very interesting.

"At one o'clock on Wednesday, the 1st of June, 1785, the Master of Ceremonies called at my house and went with me to the Secretary of State's office, in Cleveland row, where the Marquis of Carmarthen received and introduced me to Mr Frazier, his under secretary, who had been, as his lordship said, uninterruptedly in that office through all the changes in administration for thirty years. After a short conversation, Lord Carmarthen invited me to go with him in his coach to court. When we arrived in the anti-chamber, the Master of Ceremonies introduced him and attended me while the Secretary of State went to take the commands of the King. While I stood in this place, where it seems all ministers stand upon such occasions, always attended by the Master of Ceremonies, the room was very full of Ministers of State, Bishops, and all other sorts of courtiers, as well as the next room, which is the King's bedchamber. You may well suppose I was the focus of all eyes. I was relieved, however, from the embarrassment of it by the Swedish and Dutch Ministers, who came to me and entertained me with a very agreeable conversation during the whole time. Some other gentlemen whom I had seen before, came to make their compliments to me, until the Marquis of Carmarthen returned and desired me to go with him to his Majesty. I went with his lordship through the levee room into the King's closet. The door was shut, and I was left with his Majesty and the Secretary of State alone. I made three reverences: one at the door, another about half way, and another before the presence, according to the usage established at this and all the Northern Courts of Europe; and then I addressed myself to his Majesty in the following words:

"Sire: The United States have appointed me Minister Plenipotentiary to your Majesty and have directed me to deliver to your Majesty this letter, which contains the evidence of it. It is in obedience to their express commands that I have the honor to assure your Majesty of their unanimous disposition and desire to cultivate the most friendly and liberal intercourse between your Majesty's subjects and their citizens, and their best wishes for your Majesty's health and happiness, and for that of your family.

"The appointment of a Minister from the United States to your Majesty's Court will form an epoch in the history of England and America. I think myself more fortunate than all my fellow citizens in having the distinguished honor to be the first to stand in your Majesty's royal presence in a diplomatic character; and I shall esteem myself the happiest of men if I can be instrumental in recommending my country more and more to your royal benevolence, and of restoring an entire esteem, confidence, and affection; or, in other words, 'the old good nature and the good old humor,' between the people who, though separated by an ocean, and under different governments, have the same language, a similar religion and a kindred blood. I beg your Majesty's permission to add, that although I have sometimes been instructed by my country, it was never in my whole life in a manner so agreeable to myself."

"The King listened to every word I said with dignity it is true, but with apparent emotion. Whether it was my visible agitation, or I felt more than I could express, that touched him, I cannot say; but he was much affected, and answered me with more tremor than I had spoken with, and said—

"Sir: The circumstances of this audience are so extraordinary, the language you have now held is so extremely proper and the feelings you have discovered so justly adapted to the occasion, that I not only receive with pleasure the assurance of the friendly disposition of the United States, but I am glad the choice has fallen upon you to be their minister. I wish you, sir, to believe that it may be understood in America, that I have done nothing in the late contest but what I thought myself indispensably bound to do, by the duty which I owed my people. I will be frank with you. I was the last to conform to the separation; but the separation having become inevitable, I have always said, as I now say, that I would be the first to meet the friendship of the United States as an independent power. The moment I see such sentiments and language as yours prevail, and a disposition to give this country the preference, that moment I shall say, let the circumstances of language, religion, and blood have their natural, full effect."

"I dare not say that these were the King's precise words; and it is even possible that in some particulars I may have mistaken his meaning: for although his pronunciation is as distinct as I ever heard, he hesitated sometimes between members of the same period. He was indeed much affected, and I was not less so, and therefore I cannot be so certain that I was so attentive, heard so clearly, and understood so perfectly, as to be confident of all his words or sense. This I do say, that the foregoing is his Majesty's meaning, as nearly as I can recollect it.

"The King then asked me whether I came last from France, and upon my answering in the affirmative, he put on an air of familiarity, and, smiling, or rather laughing, said, 'I here is an opinion among some people that you are not the most attached of all your countrymen to the manners of France.' I was surprised at this, because I thought it an indiscretion, and a descent from his dignity. I was a little embarrassed; but, determining not to deny the truth on the one hand, nor lead him to infer from it my attachment to England on the other, I threw off as much gravity as I could, and assumed an air of gravity and a tone of decision, as far as was decent, and said, 'That opinion, sire, is not mistaken: I avow to your Majesty I have no attachment but to my own country.' The King replied as quick as lightning, 'An honest man will have no other.'

"The King then said a word or two to the Secretary of State, which, being between them I could not hear, and then turned round and bowed to me, as is customary with all kings and princes when they give the signal to retire. I retreated, stepping backwards, as is the etiquette; and making my last reverence at the door of the chamber, I went to my carriage."—*Hagueard's N. E. Gazetteer.*

It is mentioned as an interesting fact by the Lynn Patriot, that a person may now travel from Lynn or Salem, to Bombay, in the East Indies, entirely by steam; and the time required to accomplish the journey is but six weeks. He can go to the city of Jerusalem in one month.

TEACHING CHILDREN TO LIE.

My nearest neighbor, when I resided in Connecticut, was a man moving in the ordinary walks of life, and was a prudent, careful, honest, and industrious husbandman. Being at a certain time on some occasion at his son-in-law's, one of the boys of the family wished to go home with his grandfather; it not being convenient at that time, the grandfather told the boy that he could not very well carry him at that time, but added, "Next time grandpa comes he'll carry you home with him." The boy was pacified. The old gentleman not thinking any more, (as, alas! many careless and faulty parents do,) of what he had said to the boy, was several times at the house without fulfilling his engagement; and, perhaps, without once having it come again into his mind. But the boy was not so forgetful. He recollected well the promise of his grandpa. In process of time the grandfather took the boy behind him on his horse, and was conveying him to his paternal abode. On the way the boy began to remonstrate with his grandfather on the subject, by saying, "When grandpa was at our house one time, he said the next time he came he would carry me home—and grandpa did not."—"Why," says the old gentleman, "you don't think your grandpa would lie, do you?" "I don't know," says the boy, "What does grandpa call it?" This confounded the old gentleman, and he knew no what reply to make. This anecdote has convinced me more than almost any thing I ever heard, of the importance of regarding strictly and conscientiously what we say to children. Especially it has shown me the evil of trifling with children, and making them unmeaning promises or declaration which have attached to them no truth or significance. And it is my deliberate and fixed opinion that oftentimes parents, by disregarding, forgetting and neglecting to fulfil what they declare unto children in promises or threatenings, are chargeable with the pernicious evil of teaching their children to lie; and then perhaps inflicting punishment upon them for the crime. This is hard,—this is cruel,—this is an evil of a monstrous size, prevalent and triumphant to an alarming degree, and which ought speedily and effectually to be corrected. Watch then, and remember to make good what you say to children. Do not threaten them with what you have no business to execute,—such as cutting off ears, taking off skin, &c. In this way you weaken your own hands; render the truth doubtful, and train up your child for falsehood and crime. Whatever else you neglect, yet by no means neglect to teach them by precept and example, an inviolable regard to the truth.—*Youth's Journal.*

"Milk is so dear," exclaimed a young widow to her milkman, "I wish I could afford to keep a cow of my own." "Wouldn't it be cheaper, ma," replied her little daughter archly, "to keep a *mil* man of our own."

It is stated by the Mayor of Boston that one-fifth of the taxation of the city goes to the public schools.

FIRST AGRICULTURAL MEETING.

I gave in our last number a portion of Mr. Webster's speech at the first agricultural meeting, the evening previous to our paper's going to press, on the subject of English Husbandry in common with that of Massachusetts. We are not at all perfect with reporting speeches. We practise a more imperfect short hand. Our notes are few; we mainly rely upon our recollection to give the leading sentiments uttered in cases where we were not present. We are happy in believing that our readers will in this case deem even our imperfect reports better than none; though they fall very far short of doing justice to the speakers.

The hurry of writing off the speech from our memory, and some errors occurred, which it is desirable to correct. The southern parts of England are not as there stated, but a thin light loam resting on a chalk. Beans and peas are not green crops, but white and exhausting crops, but they are allowed to perfect their seed. That one bushel of oats was raised ten bushels of corn could be produced, should have been stated in the form of a supposition and not as an ascertained fact. The case of the person alluded to as employed through the winter in digging turnips should have included also his slicing them and giving them to the sheep; and this is the winter of hundreds in England.

I give these corrections in justice to Mr. Webster, and have also the pleasure to say that Mr. Webster's request, has engaged, as soon as his leisure permit, after he reaches Washington, to read out and enlarge his speech on this occasion, and then propose to issue it in a pamphlet form; I hope at the same time to be able to add a corrected report of the instructive remarks of Messrs. Silliman on the same occasion, of which I give an imperfect abstract. We know it will be received with great interest and pleasure by the agricultural public.

H. C.

WEBSTER proceeded in his remarks to state a subject which now most strongly attracted the public attention was that of the drainage of lands. The draining to which he alluded was what is called tile draining, of England, as he had stated, was based upon a retentive subsoil. Wetness is prejudicial and destructive to the crop. Marginal drains on the outside of the fields, do not always give the desired results. These tile drains have the most important improvements. The tiles are made of clay, baked like bricks; about one length, four inches in width, three fourths of an inch in thickness, and stands from six to eight inches in height, being hemispherical, or like the cylinder with its sides elongated. It resembles the Dutch tiles sometimes seen on the roofs of old houses in Albany and New York. A tile sunk eighteen to twenty inches in depth,

and these drains are multiplied over a field at a distance of seven yards apart, and vast estates have been drained in this way. The ditch being sunk and the bottom made smooth, these tiles are laid down with the hollow side on the bottom, the ends placed near each other, and some straw put over the joints to prevent the admission of dirt. These are not so expensive a mode of draining as might be supposed; but so important and useful are they considered, that even a large expense is soon met by the immediate benefits resulting from them. It has added every where at least twenty per cent. to the amount of the wheat crop. A beautiful example came under his own observation not long before he left England. On a part of a field, which had been thus drained, the wheat presented a most luxuriant growth; while on a part of the same field, which had not undergone this operation, the wheat, sowed at the same time, was feeble and just showing itself in straggling parcels above ground. It seems a singular fact that the advantages of this thorough draining are as perceptible in dry as in wet weather. A great evil in clay soils is that they become in dry weather hard and baked, and impermeable to the roots of the plants. The water, by this thorough system of draining being removed quickly from such soils, they are less subject to become hardened by the sun; and remain porous and friable.

There was another improvement which he witnessed, and which he considered as the most remarkable and beautiful agricultural improvement which had ever come under his observation. This was an instance of irrigation. Irrigation is much practiced in Wiltshire in the south of England. He had repeatedly heard of water-meadows; but he had not been able to form a very satisfactory notion of what was intended by that designation. At the Duke of Portland's estate he had an opportunity of witnessing this extraordinary agricultural improvement in a remarkable form. This was in the north of England at a place called Sherwood forest. By a forest in this case you are to understand an extent of country with a thin arid soil, covered with heath and ling, resembling brakes, with here and there a few oaks scattered upon it. Ten years since this land was not valued at a rent of one shilling per acre. It produced nothing. A brook ran near it. This brook passed through a village and gathered some of the refuse matter from the houses. It was conducted by a carrier or canal, similar to the water-way of a factory or the feeder of a canal, along the edge of this tract of land proposed to be irrigated, and suffered to ooze or pass out in small quantities over the land. Successive embankments or barriers were erected to receive and convey the water, and in this way the whole field was irrigated. The water was never permitted to flood the land but was let out in small quantities, and the field was watered in March, May, July and October. No manure was ever put upon this land; and when Mr. Webster was there in November, they were then taking off the third crop of hay cut that season; and which certainly was not less than two tons to the acre. After this crop was

gathered, sheep were to be turned in upon it, which were expected to lamb at Christmas, so that the lambs might be ready for the market in March, when they would command a high price. There can be no doubt that the sediment deposited by the waters, which they had collected in their transit through the village, contributed much to the extraordinary fertility and productiveness of the land; but there can be as little doubt that pure water itself is an element of immense value in agriculture, and that it contains essentially and abundantly the food of plants.

With respect to implements of husbandry, Mr. Webster was of opinion that the English had no advantage over us. Their wagons and carts were not better; their ploughs he considered inferior; their threshing machines inferior to those in use among us. The drill cultivation was a remarkable feature in English husbandry, and executed with great neatness and precision. The young wheat fields appeared like rows of onions. Some of the drill machines were constructed so as to drop small portions of compost manure with the seed at the time of sowing. In this matter he remarked upon our deficiency. Their ground is finely prepared. He saw a field in turnips, where the seed which was carefully soaked and prepared, was sowed on Friday, and the rows of plants were distinctly seen on Monday all over the field. This rapid germination, where it can be effected, has great advantages.

There were various other matters in English agriculture upon which he would gladly remark, though at the risk of taxing too severely the indulgence of the meeting. There were crops cultivated among them of which we had none. The English bean, a small brown bean, was much liked, and produced about forty bushels to the acre. It constituted an excellent feed for their horses.*—

*THE BEAN (*Vicia Faba*.)—“The bean is a valuable field plant, as affording food for live stock and in part for man. The varieties of the bean are two, garden and field beans, the white and the grey beans. The best soils for beans are clay and strong loams. On such soils they generally succeed wheat or oats, but sometimes also clover leys. Turnip soils or sands are by no means proper for them. The climate most favorable to the bean is one neither very dry nor very moist; the first brings on the fly; and the last prevents the setting of the blossoms. The flour of beans is more nutritive than that of oats, as it appears in the fattening of swine.” Dr. Darwin thinks them a cheaper provender for horses than that of oats; but being of an oily nature, more difficult of digestion than oats, and he would therefore hesitate in giving them the preference for this object.”

The bean is considered as an exhausting crop; but on account of the clean cultivation which is given to it, it often favorably precedes wheat. Our own experiments in the cultivation of the English field bean, which we tried two or three years, resulted in disappointment, as they were in every instance destroyed by a little black fly. This is the great enemy with which they have to contend abroad. Forty bushels to the acre must be regarded as a large yield. From twenty to thirty-five is more common.

The cultivation of the white beans among us is pursued to a very small extent and in a very slovenly and negligent manner. Land that is under a curse and considered fit for nothing else, is usually selected for a crop of white beans; and a farmer would as soon think of dressing his children in peacocks' feathers, as of giving

Vetches or tares, likewise, a sort of pea, was very much cultivated: it was customarily sowed in the fall for sheep, and was eaten by them in the fall and winter.*

The sheep husbandry in England is an immense interest. They will this year cut from sixty to seventy millions of fleeces; and sheep under one year old are not shorn. The average yield may be six to seven pounds to a fleece. There are two principal classes of sheep in England, the long and the short woolled sheep—the Leicestershire and the South-Down. The long-wooled, or Leicester sheep give a fleece of about eight pounds; the short-wooled or South-Down, a fleece of from three to four pounds. Wool is of great importance to them,

any manure to his white beans. The result is exactly what, under such circumstances, is to be expected. We have no doubt that under proper cultivation, beans may be made a highly productive and valuable crop. For feeding sheep, especially fattening wethers, we have tried and know their value. Intermixed and ground or alternated with Indian corn, they are exceedingly favorable to the thrift of sheep, and may be to a degree profitably used, notwithstanding the customary difference in price. We can hardly expect, however, that they should take the place of Indian corn; a crop which cannot be grown in England, which is not more exhausting than any other grain crop allowed to perfect its seeds, which when consumed on the farm under good management, returns a large amount to the land; and the rough fodder of which, when well cured, is almost an equivalent for the cost of cultivation.—H. C.

*THE TARE OR VETCH (*vicia sativa*.) is a plant which we have sometimes seen growing, but rarely cultivated among us. There is no hindrance in our climate to its cultivation; and perhaps the great reason why the cultivation of the tare or the field bean has been neglected or not introduced, has arisen from our capacity to produce Indian corn; and our high estimation, which can hardly be extravagant, of its value as food for the brute and the human animal. As green feed especially, and for the purposes of soiling, undoubtedly the tares might be introduced to great advantage.

"The Tare," says Low,* "is one of the most esteemed of the leguminous plants of this country, (England.) When used as green forage, they are cut after the pods are formed, but long before the seeds are ripe. Being in the class of crops not allowed to mature their seeds, they are not exhausting to the soil. They are considered as restorative crops, from the quantity of manure which the consumption of them affords. They are exceedingly nutritious, and supply a larger quantity of food for a limited period, than almost any other forage crop. All the animals of the farm are fond of this legume, and all thrive upon it in an eminent degree. Hogs may be fattened entirely upon it. It causes milk cows to give more butter than any other species of food, and it is employed extensively in the feeding of horses. All the English agriculturists are impressed with a high opinion of the value of tares."

Young observes, "tare crops are of such use and importance that not one-tenth of the stock could be sustained without them; horses, cows, sheep and hogs are all fattened upon them; hogs are soiled upon them without any other food. This plant maintains more stock than any other plant whatever. Upon one acre Davis maintained four horses in much better condition than upon five acres of grass. Upon eight acres he has kept twelve horses and five cows for three months without any other food. No artificial food whatever is equal to this excellent plant."

"Tares cut green," Professor Thayer observes, "draw no nourishment from the soil whatever; while made into hay they afford a fodder preferred by cattle to pea straw, and more nutritious than hay or any other herbage."

"These high encomiums on this plant will, we hope, induce the attention of our farmers strongly to the subject, that experiments may be made among ourselves of their adaptation to our climate and soil; and of the expediency of introducing them among a rotation of crops in our system of husbandry, if we are so fortunate presently as to have a system."

We shall hereafter resume this subject, and give the best information we can obtain in relation to the whole matter.—H. C.

and mutton in their markets commands high prices. Sheep are to be considered at the head of their agricultural products. The great importance of providing for them, therefore, must be obvious.

Our climate, as has been observed, differs from theirs; but the great inquiry applicable in equal force to both countries is, how can we manage our land in order to produce the largest crops, while at the same time we keep up the condition of the land, and place it if possible in a course of gradual improvement? The success of farming must depend in a considerable degree upon the animals produced and supported on the farm. The farmer may calculate in respect to animals upon two grounds of profit, the natural growth of the animal, and the weight obtained by fattening. The skilful farmer, therefore, expects where he gains one pound in the fattening of his animal to gain an equal amount in the growth. The early maturity of stock is consequently a point of much importance.

Oxen are rarely reared in England for the yoke. In Devonshire and Cornwall, ox teams are employed; but in travelling one thousand miles in England, Mr Webster saw only one ox team, and here they were driven one before the other, and in harnesses similar to the harnesses of horses. Bullocks are raised for the market. It is highly desirable, therefore, both in respect to neat cattle and sheep, that their growth should be rapid and their fattening properties favorable, that they may be early disposed of, and consequently the expense of production lessened.

Is it practicable on the soil and in the climate of Massachusetts to pursue a succession of crops? He cannot question it; and he had entire confidence in the improvements to our husbandry and the great advantages which would accrue from a judicious rotation of products. The capacities of the soil of Massachusetts were undoubted. One hundred bushels of corn to an acre had been repeatedly produced, and other crops in like abundance. But this would not effect the proper ends of a judicious and profitable agriculture, unless we could so manage our husbandry that by a judicious and proper succession of crops, the land would not only be restored after an exhausting crop, but gradually enriched by the cultivation. It is of the highest importance that our farmers should increase their power of sustaining live stock, that they may therefore obtain the means of improving their farms.

He had already remarked that in some things, we had the advantage of them, particularly in agricultural implements. He had seen often the plough with wheels, but he deemed it an awkward and cumbersome instrument.

The live stock of England was in a high state of improvement. He had seen the fine herds of Lord Spencer, Mr Bates and others, with high satisfaction. The specimens of the improved Short Horns brought to this country have been a capital stock; but the character of the stock raised among us should have reference to the nature of our climate. Our present breed of oxen are beyond doubt best suited to the plough. He was inclined to believe that no stock for the dairy among us and upon our short pastures, could be found superior to the Ayrshire breed of cows. Every effort should be made to improve our own breeds. The Devonshire stock brought here at an early period and now generally diffused over New England, would probably prove the best stock upon the whole for us. It undoubtedly admitted of great improvement.

He urged attention strongly to the seeds of

grains which we sowed. Great improvements had been made in these matters by a careful selection and culture. He considered that the introduction of the Leicester and South Down sheep among us would prove an eminent advantage. The Leicester require extraordinary feeding, and must always be kept fat. The South-Down were an exceedingly profitable animal both for wool and mutton; and would subsist well in short pastures and an exposed climate. It is not advisable to cross the Leicester with the Merino, or indeed the long-wooled with the short-wooled rases.

It was easy to see the immense importance of a successful agriculture to England; and that even a small amount of one per cent. added to their agricultural products would materially affect the subsistence and comfort of millions.

It was often said that England was a garden. This was a strong metaphor. There was much poor land and some poor cultivation in England. But he had looked at their improvements with the highest pleasure and admiration. In association for the improvement of agriculture, in agricultural societies, we had gone before them. He would not say that they were following our example, but that they were now doing what we had done. He had taken pleasure in attending the first meeting of the British National Agricultural Association; and gentlemen of the highest distinction in rank, talents and wealth, were apprized of the great importance of this vast national interest, and were lending their hearty co-operation in the cause. They had made in England immense advances in agriculture, and nearer approaches to the perfection of the art than in any other country.

He concluded by adding that he had on the whole seen some few individuals of the Leicester and South Down breeds of sheep, which, not as the finest, but as fair examples of these valuable breeds, he would be happy to exhibit to the farmers of Massachusetts. They would on their arrival remain in Boston some time for this purpose. He had likewise brought over a few bushels of the best kinds of wheat grown in England for seed, which would be left at the Agricultural Warehouse of Messrs Breck and Co. that the farmers, if they chose, might avail themselves of it.

After Mr Webster closed his remarks, the Commissioner announced to the Chair, that the meeting was honored, as he was most happy to see, by the presence of a distinguished gentleman from a neighboring State, familiar with researches into natural science; and as allusion had been made to the application of science to agriculture, he hoped the gentleman would favor the meeting with his views on this subject. Professor SILLIMAN, being then called upon by the President of the meeting, kindly responded to the call. We can give only very imperfect recollections of a short speech, which highly interested and gratified the assembly.

He began by remarking that he was taken wholly by surprise, nothing having been farther from his thoughts than to say any thing on this occasion. Indeed, after the remarks from the honorable gentleman who has just spoken, to which he had had common with others the pleasure of listening, he was little that need be said by any one. On occasion so gratifying as the present, and offering objects of inquiry and discussion so highly important and interesting, he could not, however, withhold the expression of his own personal interest in the case, and what little aid to the cause might be derived from his concurrence.

in the statement relating to British Husbandry, made by the honorable gentleman who preceded me, and in the impressions which that gentleman gathered from his observation of rural and agricultural life in England, he expressed his entire respect and sympathy. In a visit many years since made by himself to England, he derived from similar, though far less perfect opportunities of observation great pleasure; and he left the country more than thirty years ago, with a strong admiration for extraordinary improvements and advances made in great art, in that active, populous, and intellectual community.

The British nation had long since arrived at the perfection, which experience and further inquiry served only to confirm and strengthen, that came in all its influences might lend a most substantial aid to agriculture. They therefore have fully availed themselves of its aid in the examination of soils and manures, with a view to certain their uses and correctives.

The popular impressions formerly entertained, that little was to be gained in agriculture by the application of science, are, in a great measure, recalled. Nothing could have less foundation in fact. The advantages of the judicious application of knowledge to art, are every where seen. All the arts of life have their foundation in science; and all the improvements of mechanism from a wheelbarrow to a chronometer, are due to science and mechanical philosophy. It will be true in relation to every thing connected with human improvement and comfort, even in the most distant departments of life, the more knowledge we possess.

Inquiries into the nature of soils are of great importance; and in respect to many soils now either unproductive or uncongenial to certain crops, may enable us to apply the necessary alteratives or correctives. Although we cannot fabricate a laboratory the soils of a country, we can analyze their composition and ascertain their deficiencies: the deficient ingredient may be supplied although it should be in small quantity may be done in a form that may be generally applicable, and thus may essentially change the character of a soil.

The honorable gentleman has, without doubt, truly pointed out the causes of the mildness of the climate of western Europe, and especially of Great Britain; and has indicated with equal clearness and truth the causes of the comparative coldness of the Eastern countries of North America. In this connection may be remarked that the western countries of our continent enjoy a climate far milder than that of western Europe.

The climate of these western countries is affected in their position in relation to the vast Pacific ocean which produces an effect similar to that of the Atlantic ocean upon Europe, but in a far greater degree. Thus the climate corresponds to a considerable degree with that of the western shores of Europe. Its mildness is such that the plough may be used nearly or quite through the whole year. The temperature is, perhaps, considerably affected by the geological formation and by the extensive volcanoes, which stretch along its shores, many of which are still breathing forth their insatiable heat. Here every thing is on a vast scale; and agricultural products will at no distant day be abundant and highly important. We need indeed alter the climate of a country; but in some measure accommodate our husbandry to its peculiarities and variations.

The larger portion of the soils of New England, as stated by the honorable gentleman, is undoubtedly derived from granite and other primary rocks; and many of the red sandstone soils, such as those in the neighborhood of New Haven, are, in fact, composed of the principles found in granite rocks. Argillaceous soils or those which are derived chiefly from the decomposition of argillaceous or clay slate, abound likewise in many parts of New England and of Massachusetts, and being retentive of water, are found highly productive in grass and grains.

A considerable part of the nutriment of plants is undoubtedly derived from the air, and water or its elements constitutes a large portion of their food. The composition of water is now well understood, and we may with safety, in the presence of this intelligent assembly, speak in technical terms of the constituent parts of water, hydrogen and oxygen, which enter largely into all vegetables. Carbon, which forms also a large part of all plants, though it exists in comparatively small proportions in the form of carbonic acid gas in the air, is yet derived from innumerable sources and supplied to the growing vegetables in abundance. The effects of light upon the green leaves of plants is to decompose the carbonic acid, and the carbon is absorbed to nourish the plant, and the oxygen is evolved into the air; thus it separates from the atmosphere an important element of nutrition, supplying it in the form of food for the plants.

Mr Silliman farther alluded to the curious fact in the constitution of nature, that notwithstanding the superior density or specific gravity of carbonic acid gas, it being much greater than that of the other elements of which the atmosphere is composed, it is nevertheless found in abundance in the elevated regions of the earth, and even on high and barren mountains contributes in an important degree to the support of plants and of trees. If the air and water afford the most important elements of plants, it may be asked, what then is the use of the soil? Its first use is to furnish a point of support in which the plant can fix itself; but it doubtless contains many things which water serves to dissolve, and hold in solution, that they may be taken up by the plants. He expressed his belief that in most of the soils in New England and in Massachusetts, the principal element wanting is lime. This abounds in the western districts of New York, and renders those lands, as in Genesee for example, on the magnificent farm of Mr Wadsworth, extraordinarily productive in wheat.

The addition of lime to our own soils, he considered of great importance. Our sea-shores abound in shells, whose base is lime, and which are capable, by being burnt, of being converted into the best of lime. New Haven, the town of his own residence, abounds in oysters, both natives and those that in great numbers are cotized there from Virginia. The shells are burnt for manure and applied to the land. The soil of New Haven and its vicinity is derived from a species of red sandstone; but this was composed of the elements of granite quartz, mica and feldspar, the ruins of granitic and other primary rocks.

An interest in agriculture is now awakened in Connecticut which promises the most valuable results; and improvements in cultivation are rapidly advancing. He agreed in the estimation of the Commissioner, of the great value of Indian corn.—One hundred bushels had been repeatedly produced in New Haven upon an acre. A cattle show and

agricultural and horticultural fair have been held in New Haven annually for several years—the last autumn in particular, with a spirit which evinced the lively interest taken in the subject; and he had the pleasure on that occasion of seeing one hundred yoke of very fine oxen from East Haven, attached to a plough, and the plough holden by a venerable man of ninety-six years of age, who laid a furrow along the public square.

In his own opinion, there was no occasion, in an agricultural point of view, to despair of Massachusetts or any part of New England. There were no evils or disadvantages connected with the climate or soil, which could not be met and overcome. It was a great and lamentable error that so many of our young men deserted the pursuits of agriculture to crowd into the trades of cities.

He reverted again to the value and importance of chemical knowledge to agriculture. The analysis of manures was a subject of great and indispensable importance. The knowledge obtained from geological and agricultural surveys and chemical investigations, could not be too highly estimated; and the State could expend no money to more advantage than in procuring and encouraging them. This patronage should not be withdrawn or withheld; and the withholding of it could arise only from a want of a just appreciation of the value of these branches of science. He alluded with much respect to the late lamented Judge Buel, whose skill in the science and application of manures was a just subject of eulogy, and whose success, in converting a portion of the barren and unpromising soil in the vicinity of Albany into fertile and productive fields, was well known and honored.

He pressed the importance of a Board of Agriculture, and congratulated Massachusetts upon the spirit and liberality with which she had regarded the improvement of her husbandry. The subject could not receive too much of her concern. It stood second to no interest but those of a moral and religious character, and indeed it might be said to be nearly allied to them also, since habits of rural industry are the most favorable to good morals.—The value of science in this case could not be too highly estimated. Here science might be regarded as the eye, and practical skill the hand, by which this great art was to be carried forward to perfection.

IMPROVED STOCK.—We stopped a short time one day last week, to examine the stock on the farm of the Messrs Lathrop, at South Hadley Falls. They have about a dozen high bred Durham cows, remarkable for their size and beautiful form; and about the same number of young stock, mostly full blood Durham. Among their sheep we noticed a few full blood South Downs. They are the only pure blood sheep of this breed we have noticed in this vicinity. The Berkshire pigs on this farm have all the marks of the genuine. The proprietors of this farm are entitled to much credit for the exertions they have made, and the expense they have incurred, to procure so large a collection of fine stock. There is no danger of "over-issuing" stock of this kind.—*Northampton Rep.*

A farmer in Pemberton, N. J., recently slaughtered a lot of twenty-five pigs, whose aggregate weight, after they were dressed, was eleven thousand eight hundred and twenty-five pounds. The average weight was four hundred and seventy-three pounds.

From the Journal of the English Agricultural Society.

PRESENT STATE OF THE SCIENCE OF AGRICULTURE IN ENGLAND.

[Continued.]

There is no department of agriculture in which minute inquiry is more needed than this: first, to examine accurately the various diseases of plants, and to note the habits of the animals which prey on them; then to ascertain, if possible, the remedies that may be applied; and the followers of kindred sciences may be fairly invited to aid us in the formation of this branch of knowledge, which may be called agricultural pathology. But even when the crop is ready for harvest, it must not be supposed that there is no doubt remaining, no room for further improvement. With regard to corn, much injury arises to it from its being exposed to wet after it has been cut, when it may be discolored at least, and often begins to grow in the sward or the sheaf. If left too long, on the other hand, in the hope of dry weather, it becomes overripe, and a portion of the grain is lost by being shed on the ground. It is no new remark, however, that as soon as any portion of the straw has turned yellow, the ascent of sap from the root is cut off, and that though the ear be partly green, it will ripen henceforth as well when severed from the ground as it will if it be left standing. If this supposition be correct, it might enable the business of harvest to be commenced earlier, when a clear sky invites the reaper into the wheat field; and would be so far beneficial, though not in a very material degree. The late ripening of the corn in the northern parts of this island, where from the moisture of the summers following cold springs, crops are sometimes not secured for two months after our southern harvest is ended, requires a more effectual remedy if such can be found; and it has been suggested, that as seed grown in southern climates retains for some time its habits of early ripeness, though grown under the more chilly sun of the north, seed might be advantageously borrowed by our northern farmers from the warmer parts of the country. The suggestion, however, can be regarded as yet merely as speculative. But the power of improvement does not cease when the corn is placed in the rickyard; and here we have not to inquire or to guess, but simply to look at the practice of the practical farmer in the Lothians and in Northumberland. There, instead of the thrasher and his flail, may be seen the machine, not driven however by horses, for then the advantage might be more doubtful, seeing that the labor is distressing to the animals, and withdraws them, moreover, from the work of the fields, but impelled by wind or water, or steam, and that on almost every farm. In France, too, it appears that not only travelling threshing machines are employed, as is the case here, but that it is proposed to work these by steam engines carried with them. It may be objected, indeed, by the farmer, that if he gave up his hand-threshing, he would be at a loss to find employment for his men in the winter. The objection, however, shows a want of confidence in the power of permanent improvement judiciously applied on the soil to bring back its cost with interest, nor can this objection be allowed any weight as long as a single acre of the farm is stagnant with water, or dry because the soil is shallow, while there is a possibility of its being deepened. Indeed, if you once establish a moving power on your farm, whether steam, water, or wind, it is not the

labor only of threshing that may be saved to men or horses, but the winnowing, the dressing, the chaff-cutting; even the turnip-slicing machine, when the turnip is consumed at home, may be grafted on to the principal wheels, and thus borrow their motion. The more labor is thus set free from mere work of routine, the more will be applied to the further improvement of the parent of all agricultural labor, the soil. Having mentioned the turnip slicer, we cannot but say that, while we would willingly rest the necessity for increased intercourse among the agricultural body, upon the varying practices which prevail in different parts of England with regard to the turnip alone, a strong argument may be drawn for it from the limited use even of this implement only. It consists in some simple machinery of knives, turned by a handle, enclosed within a box, above which is a trough into which the whole turnips are placed, and below which the slices fall into another receptacle: the whole may be placed on a wheel and two legs, and moved about the field like a wheelbarrow. The advantage is two-fold, saving the teeth of the old ewes, for which the Swedish turnips, especially, are too hard; saving the waste of this valuable root, which, when partially scooped out by the sheep, is rotted and trampled about with great waste. The economy effected by this simple machine, which costs but 6 or 7*l.*, has been stated to us by an authority which would at once be admitted as very high, to be no less than one-third of the whole produce. If it be taken, however, only at a fourth or a fifth, why, it may be asked, has not every farm in the country been long since furnished with this cheap apparatus? If a contrivance were discovered in Manchester which should save one-fifth of the cotton consumed in a manufacture, (were such a saving possible,) not a year would pass before most of the old machinery would be replaced by the new, and such changes are constantly taking place there, at the expense of many thousand pounds; but the turnip is the raw material of the farmer's stock, and the farmer is of the same enterprising race with the manufacturer: why, then, but on account of the separate and secluded scene of his industry, is the spread of agricultural inventions so slow—the extension of those which concern manufactures, so rapid? and what but a central connection of the cultivators of the soil can diminish the distance and remove the obstruction?

The mention of this last instrument has brought us to a most essential element of farming, that we have hitherto passed by,—the animals, which, while they embellish and enliven rural scenery, are indispensable to the fruitfulness of the soil. It is a subject which the English agriculturist may enter upon with satisfaction. There seems indeed to be in the people of this country a peculiar disposition and talent for encouraging the finest animal forms, and producing, by careful attention to the selection of the parents, new families, in which are perpetuated, by descent, useful and symmetrical excellence. It is not only the English race-horse, improved from the Arab and Barb, that is eagerly purchased and exported to every civilized country, but the Durham bull (like him too supposed to be descended from a foreign ancestor, derived in this case from Holland,) the new Leicester sheep, and even the Berkshire hog, are the acknowledged sources from which other nations seek to enrich and refine the blood of their several live stock. National gratitude requires that, whenever the new Leicester sheep is mentioned, the name of Mr Bake-

well, of Dishley, by whom it was produced about century since, from unknown parents, should not be forgotten; nor that of Mr Colling, in connection with our beautiful short horns. This indeed has been the popular branch of English farming, among its zealous patrons may be named the late and present Dukes of Bedford, the Duke of Richmond, the Marquis of Exeter, Lord Leicester, and Lord Spencer. Such indeed is the pleasure of seeing the form of the sire reproduced or excelled the offspring, (and the coins of the Sicilian Greek show how fine is the form of the bull,) that there some danger lest the end pursued should be forgotten in the means of attaining it. Not that it is necessary in an agricultural journal to vindicate our annual shows of fat cattle, since although the cattle may be more fat than the ordinary market requires, the power of reaching that excessive size is the only test by which the capacity for acquiring useful marketable condition at the cheapest expense of food and at the earliest age, can be tried; and the encouragement of public emulation and competition. That object has been also practically attained to a high degree. The saving effected the cost of production, through the early maturity the new Leicester sheep, or of the cross between the new Leicester and Cotswold, has been calculated, by a practical farmer in Gloucestershire, nearly twenty per cent.; that is to say, it would have cost about one-quarter of the outlay more to supply the present quantity of mutton consumed in this country under the old system than by the new. This may be taken as a moderate estimate, so as the new Leicester blood and its propensity early fatness has hitherto extended. It may be worth the inquiry how far the South-Down race has been improved in this respect, or how far it may be capable of such improvement, and of thus combining rapid maturity with its own superior hardihood. There can be no doubt, however, that in many of our agricultural districts the pure improved blood, whether of sheep or cattle, is little known; and the extension of the advantages secured by the state of perfection to which these animals have already been carried into such districts will arise, it may be hoped, from the Society's cattle shows.

(Concluded next week.)

From Youatt's Treatise on Cattle.

THE LONDON DAIRIES.

The dairies of the metropolis are objects of much interest to the stranger and to the agriculturist. In the pursuit of the object of this work, we travelled over the greater part of the United Kingdom; and although we often had no other recommendation than the simple statement of the purport of our journey, we met with very few cases of incivility or of unwillingness to give us the fullest information; and when we returned to our usual residence, and when we expected most facility in the attainment of our object, we will not say that the refusal to admit was accompanied by rudeness, but the gate of the dairy remained closed. This was the case with the overgrown milk establishments. It was a species of illiberality on which we had not calculated; but it mattered little, for we had seen many of the smaller ones, and we could guess with tolerable accuracy at the difference of treatment in some points indeed they had been already whispered to us, as we had besides a minute and accurate account of them in the Magazine of our friend Mr Berry.

The number of cows kept for the purpose of supplying the inhabitants of the metropolis and its environs with milk is about 12,000. They are, with very few exceptions, of the short-horn breed—the oldness or Yorkshire cow, and almost invariably with a cross of the improved Durham blood.—The universal preference given to this breed by such a body of men, differing materially on many ranches of the treatment of cattle, is perfectly satisfactory as to their value, and that on three distinct points.

First, as to the quantity of milk. This we need not press, for the enemies of the short horns have never contested this point. There is no cow which yields so well for what she consumes in the quantity of milk that she returns.

This, however, is not all, though it may be the principal thing which enters into the calculation of a metropolitan dairyman.

The name of the new milk has something very pleasant about it, but it is an article which rarely makes its appearance at the breakfast or tea table of the citizen. That which is got from the cow at night is put by until the morning, and the cream is skimmed off, and then a little water being added, it is sold to the public as the morning's milk. The morning's milk is also put by and skimmed, and, if warmed a little, is sold as the evening's milk. This is the practice of most or all of the little dairymen who keep their half a dozen cows; and if they were all, and with these people it is nearly all, the public must not complain: the milk may be heated by the warm water, but the lowering system is not carried to any great extent, for there is no pride among them that their milk shall be better than that of the merchants on a yet smaller scale, nor do they purchase the article from the great dairies; and it is generally so. The milk goes from the yard of the great dairy into the possession of the immediate dealers perfectly pure; what is done with it afterwards, and to what degree it is lowered and acidulated, is known only to these retail merchants.

The proprietor of the large dairy is also a dealer in cream to a considerable extent among these people; he is also a great manufacturer of butter, for he must have milk enough to answer every demand, and that demand is exceedingly fluctuating; then it is necessary that the quality of the milk should be good, in order that he may turn the overplus to a profitable account in the form of cream or butter. The employment of the short-horn cow, in all the dairies, is a convincing proof that her milk is not inferior as some have described it to be.

It is the practice in most of the dairies to fatten cows as soon as her milk becomes less than four quarts a day. They are rarely suffered to breed in the dairyman's possession. The fact of their being so often changed is a proof that while cows give a remunerating quantity of milk for a certain time, she is rapidly and cheaply fattened by the butcher as soon as her milk is dry. Were the time or money employed in preparing her for the market, this system would not answer, and it could not be so universally adopted. Fattening on milking properties can, therefore, combine in some animal, and they do so here.

Mr Laycock, however, does not adopt this as a general rule. The cows that are more than usual good milkers are suffered to take the bull in season. He always keeps some good short-horn bulls for this purpose. It sometimes happens that the cow will continue to give milk

until within a few weeks of calving; and he judges, and perhaps rightly, that this is a more profitable course than to fatten and get rid of her, with the probability that he might replace her by a cow that would give a less quantity of milk.

The present market price of a good dairy cow is about 20*l.*, but the owners of the small dairies have no little trouble to get a good cow. The jobbers know that they will have a ready market for a considerable portion of their lot in the yards of the great cow-proprietors, and will probably get a larger price than the poorer man would give; and therefore Messrs Rhodes, or Laycock, or one or two others, have always the first selection. Mr Laycock has peculiar advantages for obtaining good cattle. In addition to his dairy, he has sheds that will contain five or six thousand beasts. A great proportion of them halt on his premises for a day or two before they are brought into the market. In addition to the shilling a night which he charges for their standing, he claims the milk of the cows as his perquisite. The cows are milked by his people; he therefore knows beforehand the quantity of milk which each will yield, and he is thus enabled to cull the very best of the herd. The dairymen do not like a cow until she has had her third or fourth calf, and is five or six years old; she then yields the greatest quantity of milk, and of the best quality. Two gallons of milk per day is the quantity which each cow is expected to yield in order to be retained in the dairy. Taking one cow with another, the average quantity obtained is rather more than nine quarts.

When she begins to fail in her milk, she is fattened on oil cake, grains, and cut clover hay, and disposed of. The dairyman calculates on getting something more for her than when he first bought her, but sometimes he meets with an animal that seems to verify the old prejudice against cows in good condition. He bought her for known milking properties, but she continues so poor that he in a manner hides her in some corner of his dairy. She, however, does her duty; she yields him plenty of milk, but that at length dries up; and he is unable, try what he will, to get much flesh upon her bones, and he sells her for less than half of her first price.

The quantity of milk yielded by all these cows, at 9 quarts per day, amounts to 30,420,000 quarts, or 27 quarts of genuine milk for each individual.

The retail dealers usually sell the milk for 4*d.* per quart, after the cream is separated from it, and then obtain 3*s.* per quart for the cream; besides this, a great deal of water is mixed with this skimmed milk; so that we far underrate the price when we calculate that the genuine milk sells at 6*d.* per quart, which makes the money expended in milk in the British metropolis amount to 985,500*l.* or nearly a million pounds per annum.

If we again divide the 985,500*l.* by 12,000 (the number of cows), we shall have the strange and almost incredible sum of more than 82*l.* as the money produced by the milk of each cow. This is divided among a variety of persons, and after all affords but a scanty subsistence to many of them; but it unequivocally proves the rascality that pervades some of the departments of the concern.

We acquit the wholesale dealers of any share in the rognery, nor do we believe that their profits are exorbitant. They sell the milk to the retail dealers at a price that, according to Dr Middleton, would enable them to clear 64 per cent., without adulterating the article—we believe that 50 per cent. would be nearer the truth.) When we con-

sider the nature of the business, the distance the milk girls have to travel, and the time wasted in selling their little quantities from door to door, this profit is not too great; but when they abstract the cream and add the water, and (unless they are much belied) some extraneous and abominable articles, the actual profits will far exceed cent. per cent. In the spring of the year, when London is full, the consumption and the deterioration are greatest. In the latter part of the year the cream is converted into butter, and the buttermilk given to the hogs.

(To be continued.)

PROFITABLE FARMING.—Mr James Hill, of West Cambridge, has taken in ninety successive days, five thousand dollars in cash, in Boston market, for articles raised on his farm.

Mr Isaac Locke, of the same town, has raised the present year, 30 barrels of quinces, which sold on the ground for seven dollars a barrel; he has also sold in the same way, the present autumn, several hundred barrels of Baldwin Apples at \$3 per barrel.

The value of the Strawberries raised in West Cambridge and sold in the Boston market, is more than was taken thirty years ago for all the agricultural products of the town put together.

The apple orchards of this town are extensive. Two hundred, three hundred, five hundred, and sometimes a thousand barrels of carefully picked apples are produced in a single year by one farmer.

Mr George Pierce, of the same town, cultivates only seven acres and yet he has taken in the market for produce, the present season, as by memorandum kept, nearly or quite four thousand dollars.

This season, very early, among his articles for market, was about one third of an acre of the dandelion, which grows spontaneously in many mowing fields; these he with some difficulty obtains from the seed; but the crop turns out very profitable. He had about an acre of strawberries, from which upwards of two thousand boxes of that fruit were picked last summer; these, at 37 1-2 to 50 cents a box, for which they readily sold in the market, produced not a small profit on a single acre.

Mr Pierce also cultivated the raspberry, which thrives with great luxuriance. He thinks he could make of the blackberry, which grows in the hedges and amongst piles of decayed wood or rocks in neglected fields, a profitable article.—*Monthly Visitor.*

A LARGE HOG.—We notice in several of our exchange papers an account of a very extraordinary hog raised in Wallinford, Vt. and sold for two hundred dollars to a gentleman who designs to transport him over the country as a show. He weighs, it is said, sixteen hundred pounds and is three or four years old! He is a monster indeed. We several years since saw a hog that weighed 1350 lbs., and was thought to exceed every thing in the hog line. There are, at this time in this town, several very large hogs, one owned by Mr Timothy Rix, which is estimated to weigh eight or nine hundred pounds, and is not yet, we believe, eighteen months old. Should the creature be kept until he reaches the age of "three or four years," we doubt very much whether the Wallingford hog would have much to brag of when compared with the hog of Mr R.—*Haverhill (N. H.) Republican.*

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JANUARY 22, 1840.

We publish the subjoined letter for its contents, which will be found instructive; and for another good reason, to which we invite the special attention of our friends. We mean in particular, as an answer to the circular, which three months since we addressed to the farmers, soliciting the information which they could give us respecting the application of sundry manures, particularly lime, marl, bone dust, ashes, gypsum, and compost of peat and other materials. We know that many farmers can give us on these subjects much valuable information, and we again request their attention to it.—We beg them to favor us in their way by letter per mail, with the results of their experience, promising them that we will give no names to the public without their consent, and make no use of their communications but such as may meet their approbation. H. C.

MR COLMAN—When I received your circular requesting information on the uses of composts and mineral manures, it was my intention to have taken a tour among our farmers, and collected the result of their experience with regard to these things. But my leisure has, very unexpectedly, been occupied in a different way. I shall therefore not be able to communicate so many facts to you with regard to these things as I should be glad to. Such as I have, however, it is a pleasure to communicate.

We have never tried the composts for field culture to a very great extent, but have repeatedly taken the black earth from swamps and mixed it with lime or house ashes, probably in proportion of one-third of the latter. The two substances should be well incorporated, and lie exposed to the sun a few days in small heaps, say of one load each, previous to being applied. We have found this much more beneficial to all garden crops than animal manure in any state, and almost invariably a preventive of insects. There can be no doubt but it would be found a superior article for field culture, especially for turnips. Two years since, when removing the surface, (which is very dark for eighteen inches in depth,) from the iron mines, we caused the laborers to pile the turf and soil in separate places from the subsoil, that at a convenient season we might remove it to some of the land of a different variety. In some of these heaps we put lime, though in quantities too small to have much effect. We have used this earth and its small quantity of lime (not one bushel of the latter to ten of the former,) for various crops, and have found it very good for ruta bagas, wheat and grass. That without lime we have found valuable for potatoes, if put in the hill. From one quarter of an acre where this was applied, last spring, with a spoonful of plaster thrown upon it, we harvested sixty bushels: a good crop for the season. The soil on which this experiment was tried, was an exhausted loam. We tried that with lime for corn on a loam by the side of hog manure on one side and stable manure on the other. That manured with compost was about three-fourths as heavy as the former, and ripened well. We cannot recommend it for use to the exclusion of animal manures, but where, as there is every where, a lack of them, we think it well worthy of the farmer's notice. Probably had our experiment been made with pure swamp mud instead of a soil that has been under cultivation for half a century, it would have succeeded much better than it now did.

We find a great benefit in mixing the manures of dif-

ferent animals. Horse manure is too hot and dry for most soils. Hog manure is too strong, and encourages too great a growth for good earing; but when these are mixed with those of cattle and sheep, their objectionable qualities as single manures are imparted to the others, and the qualities of all increased. Earths thrown in with them become a part of them and increase their quantity.

Bone dust.—The first experiment with this article heretoback which has ever come to my knowledge, has been tried on a field of turnips this season. The land was one of our clayey hills. After the turnips were sown, the dust, at the rate of about four bushels to an acre, was sown along the drills of all except two in the centre. These through the season showed that they had been slighted, and at harvest time they showed their resentment by refusing to yield the cultivator a single turnip for his labor. Those on the part dusted were large and as clean as we ever saw. We have no doubt but bone dust will eventually become a very common manure in the country.

Yours, &c.

W. BACON.

Mount Osceola, Dec. 26, 1839.

AGRICULTURAL MEETING.

The Agricultural Society of Westboro' and its vicinity assembled on Thursday, 2d inst. and held a meeting in the Town Hall in the afternoon, where an address was delivered, and adjourned until five o'clock, when they sat down to a sumptuous repast. They met again at a public hall in the evening for an intellectual feast and held a discussion on a subject which had been before assigned for consideration.

The question presented to the meeting was—What is the operation of the alkalies, lime, ashes, and gypsum upon vegetation?

The discussion was opened by Dr Burnet, in a lucid and instructive exposition of his views, coinciding in the main with the views of Dr Dana on this subject, as given in the second report of Prof. Hitchcock, in his re-examination of the Economical Geology of Massachusetts. Dr Burnet was followed by Messrs Brigham, Mr Ford, Mr Chamberlain, Mr Denny, Mr Church, Mr Fay and other gentlemen; and the evening was spent in perfect good humor, and was altogether adapted to promote inquiry, experiment, and agricultural enterprise and improvement.

Dr Burnet gave it as his opinion that the operation of all the alkaline manures is the same; that they are not in themselves the food of plants; and that their principal use is to render the vegetable pabulum, the food of plants, scientifically denominated gine, soluble, and put it in a condition to be taken up by their roots. The question before the meeting was as to what is the nature of the operation of these substances. Several gentlemen went into the statement of facts within their own experience, to illustrate their actual effects, as indeed in the limited range of human inquiries, the best means of arriving at some correct notions of the mode of their operation.

These facts were highly interesting. There was scarcely an exception to the conviction that ashes in their application were almost invariably beneficial and powerful. Mr Church had found no perceptible advantage from them when applied round the corn on the surface at the time of hoeing. Mr Ford had found great benefit from this application. The circumstance of this difference in the results is not easily determined, as all the circumstances of the case were not minutely stated. It would seem in Mr Ford's case that rain fell immediately after the application of the ashes, and their efficacy upon the crop appeared to follow at once. It is easy to

suppose that this rain may have contributed to carry the efficacious ingredients of the ashes at once in a liquid form to the roots of the plants: but we hazard no theory of its operation.

Several gentlemen had applied lime, most of them in some mixed form, either compounded with mud or peat, or as in Mr Fay's case, in a compound of lime one half, ashes one quarter, and gypsum one quarter; but as well as we can remember, there was not a case mentioned where it had been applied separately and in such a form that its efficacy or inefficacy could be fairly tested, that it had proved evidently efficient. The statement of Mr — Brigham seemed conclusive, that in its application to a crop of wheat, although its effects were not seen upon the wheat, yet upon the grasses, which followed the succeeding year, the effects were decisive and highly beneficial.

We do not undertake to give any thing like a report of the discussion on this subject. We can only say that it was conducted with perfect urbanity and mutual gratification and advantage.

This society has made a capital beginning; and if they can but keep up the spirit with which they have begun, the meetings will prove occasions not only of agreeable entertainment as matter of social intercourse, but directly promotive of the agricultural improvement of the vicinity and the State. We are happy in thinking that some men have got hold of the handles of the plough in this case, who will not be disposed to look back. H. C.

ELECTION OF GOVERNOR.

The Legislature of the State assembled on Wednesday, the first day of January, and opened the session.—The division of parties approaching nearly to an equality, the perfection of the organization of the government has proceeded slowly. The matter, however, was completed on Saturday, by the inauguration of Marcus Morton as Governor, and George Hull as Lieut. Governor of Massachusetts for the current year.

It is not for us to enter the political arena, if we had the disposition to do it; but we have not the honor, that we believe that neither Massachusetts nor any other State ever had a more accomplished, punctual, conscientious, faithful magistrate than has just left the chair of State; and we think it would be impossible for the bitterest enemy, if he has any enemies, to point to a single act of omission or commission, marked by intentional error. Mistakes of judgment there may have been; but if any have occurred, they are as few as ever marks the course of any man. He retires under the enviable consciousness, the highest and purest reward which any good man can ask or desire, of having faithfully performed his duty and fulfilled his trust; and of having failed in no respect whatever of meeting the high expectations of those by whose suffrages he was elevated to office.

He has been displaced not for any failure in duty or through any distrust of his eminent qualifications for any place of trust and office, to which his fellow-citizens may see fit to advance him; but in the struggles of parties and the evenly balanced condition in which they stand to each other at the present time in the State, he has failed of his election; and the popular voice has placed another gentleman in power. In our form of social arrangement and government, it becomes the duty of every good citizen in such a case to acquiesce cheerfully in the lawful decision of the majority.

It is a subject of honest pride and of just congratulation, that the State has many excellent and intelligent citizens, in every respect qualified to discharge with honor to themselves and benefit to the community, the duties which it may demand of them. In this case we have reason to congratulate the commonwealth and country on the elevation to the highest office of dignity and authority in the commonwealth of a gentleman, who by his exemplary and irreproachable character, his legal acquirements, his long experience, his eminent talents, and his intelligent and honorable performance of the public duties in which through life he has been engaged, is highly qualified for the trust which has devolved upon him. It becomes every good citizen to regard him with the respect due to his character and the

est wishes for his success; and to merge every private consideration in a sincere concern for the public honor and the general welfare.
H. C.

MR. WEBSTER'S SEEDS NOT YET ARRIVED.

At the Agricultural meeting at the State House on an evening of the 13th, Mr. Webster stated that he had selected some seeds while in England, which he thought could be important to introduce into this country, and that he had ordered them to the Agricultural Depot in this city, Nos. 51 & 52 North Market Street, where those who wished to try them would have the opportunity to procure them. As there has been considerable inquiry about them, we would inform our agricultural friends that they are on the way from New York: as soon they come to hand we shall give notice in the N. E. Farmer, and publish a list of the seeds.

JOSEPH BRECK & CO.

N. E. Farmer Office, Boston, Jan. 21st, 1840.

NOTICE.

The Flower Committee of the Massachusetts Horticultural Society are respectfully requested to meet at the Rooms of the Society, 23 Tremont Row, on Saturday next 23rd inst. at 11 o'clock, A. M., for the purpose of awarding premiums for the past year.

Per order, S. WALKER, Chairman.

BRIGHTON MARKET.—MONDAY, JAN. 20, 1840.

Reported for the New England Farmer.

At Market 320 Beef Cattle, and 800 Sheep. About 300 Sheep were reported last week.

Prices.—Beef Cattle.—The Butchers were largely supplied last week, consequently purchased less, and did not advance as much as was expected from a limited number at Market. We quote First quality, \$5 a \$6 50. Second quality, \$5 75 a \$6 00. Third quality, \$4 75 a \$5 50.

Wooling Cattle.—Mess \$5 50; No. 1 \$5 00.

Hides and Calves.—Very few at market and very low sales effected.

Sheep.—Lots were sold at \$2 50, \$2 75, \$3 00, \$3 50, \$4 50, and \$5 00.

Pigs.—None at market.

THERMOMETRICAL.

Reported for the New England Farmer.

Use of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded early exposure, week ending January 19.

Jan., 1840. | 7 A.M. | 12, M. | 5 P.M. | Wind.

Mode of the Beet and Manufacture of Beet Sugar.

published and for sale at the N. E. Agricultural Warehouse and Seed Store, a treatise on the Culture of the Beet and Manufacture of Beet Sugar, by David Lee Child, 5 cents.
January 22.

A MAN WANTED.

to work on a small place, a few miles from the city, to manage the cultivation of vegetables, &c., and the care of horse, cows, &c. A single man, of 30 years of age, of steady and industrious habits, and of a temperate life. J. B. I.
January 13.

ROHAN POTATOES.

for sale at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at 85 per barrel.
January 16. JOSEPH BRECK & CO.

VEGETABLE CUTTER.

Willis's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and excelling roots for fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public: they are aware that it has been long wanted and they now offer a machine that cannot fail to give satisfaction upon a fair trial. It will cut with ease from one to two bushels per minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at the Agricultural Warehouse, 51 and 52 North Market Street, December 13. JOSEPH BRECK & CO.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO. at the New England Agricultural Warehouse and Seed Store, Nos. 51 and 52 North Market Street, have for sale, Green's Patent Straw, Hay and Stalk Cutter, operating on a mechanical principle not before applied to any implement for this purpose. The most prominent effects of this application, and some of the consequent peculiarities of the machine are:

1. So great a reduction of the quantum of power requisite to use it, that the strength of a half grown boy is sufficient to work it very efficiently.
2. With even this moderate power, it easily cuts two bushels a minute, which is full twice as fast as has been claimed by any other machine even when worked by horse or steam power.
3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.
4. The machine is simple in its construction, made and put together very strongly. It is therefore not so liable as the complicated machines in general use to get out of order.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure. He keeps constantly on hand a supply of Ground Bone, and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and no charge for casks or carting. Also, ground Oyster Shells. Orders left at the Bone Mill, near Tremont row, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

NAHUM WARD.

AMERICAN SWINE BREEDER.

Just published and for sale by JOSEPH BRECK & CO. the American Swine Breeder; a Practical Treatise on the Selection, Rearing, and Fattening of Swine, by Henry W. Ellsworth: price 75 cents.
January 15.

MISCELLANEOUS.

THE COTTAGE DOOR.

BY T. E. HERVEY, ESQ.

How sweet the rest that labor yields
The humble and the poor,
Where sits the patriarch of the fields
Before his cottage door!
The lark is singing in the sky,
The swallow in the eaves,
And love is beaming in each eye
Beneath the summer leaves!

The air amid his fragrant bowers
Supplies unpurchased health,
And hearts are bounding 'mid the flowers
More dear to him than wealth;
Peace, like the blessed sunlight, plays
Around his humble cot,
And happy nights and cheerful days
Divide his lowly lot.

And when the village Sabboth bell
Rings out upon the gale,
The father bows his head to tell
The music of its tale—
A fresher verdure seems to fill
The fair and dewy sod,
And every infant tongue is still,
To hear the voice of God!

Oh! happy hearts!—To Him who stills
The ravens when they cry,
And makes the hily 'neath the hills
So glorious to the eye.
The trusting patriarch prays, to bless
His labor with increase;—
Such "ways are ways of pleasantness,"
And all such "paths are peace!"

RULES FOR HOUSE WIVES.

1. When you rise in the morning, never be particular about pinning your clothes so very nicely; you can do that at any time.

2. Never comb your hair, or take off your night cap till after breakfast. It is your business to take time by the foretop and not let him take you so; therefore keep all right in that quarter till ten o'clock at least.

3. When you begin the business of your toilet, you may do it before the window or in the front entry; but the most proper place is in the kitchen.

4. Never have any particular place for any thing in your house; and then you may rest assured that nothing will ever be out of place; and that is a great comfort in a family.

5. Never sweep your floor, until you know some person is coming in; he will then see how neat you are; and, besides, in such cases, even your enemies cannot shake off the dust of their feet, against you, though they may the dust of their clothes with which you have covered them by your sweeping.

6. When you have done sweeping, leave your broom on the floor, it will then be handy; and being always in sight, and in the way, it will be constantly reminding your husband, when he is in the house, what a smart, nice, pains-taking wife he has.

7. Never follow the barbarous practice of brushing down cobwebs. A man's house is his castle; and so

is a spider's. It is a violation of right, and a shameless disrespect to the fine arts.

8. Keep your parlor and bedroom windows shut as close as possible in dog days; this will keep the hot air out—and you will have excellent fixed air inside.

9. Keep your summer cheeses in your bed chambers;—they enrich the qualities of the atmosphere; and if a stranger should lodge in one of your beds, if he could not sleep, he could eat for his refreshment.

10. Never teach your daughters to mend or make any of their own clothes; it is "taking the bread from the mouth of labor"—besides it will make them crooked and give them sore fingers.

11. But if they should insist on mending their own garments, they should do it while they are on; this will make them fit better; and girls can't leave their work—if they should attempt it, their work would follow them.

12. If your husband's coat is out at one of the elbows, don't mend it until it is out at the other; then the patches will make it appear uniform, and show that you are impartial.

13. Never spoil a joke for a relation's sake; nor suppress the truth for any body's sake. Therefore, if you don't like your husband as you ought, out with it, and convince him you are not a respecter of persons.

14. You should endeavor not to keep your temper; let it off as soon and as fast as you can; and you will then be calm and quiet as a bottle of cider after the cork had been drawn half a day.

15. If, on any particular occasion, you are at a loss as to the course you are to pursue, in the management of yourself or family affairs, take down the paper which contains these rules, and read them over and over till you have satisfied your mind—and then go on.—*Methuen Gazette.*

INGENUITY OF RATS.—The rat, that "hateful and rapacious creature," as Goldsmith honestly designates it, formerly abounded in prodigious numbers in Inverness, and a traveller, about the year 1730, describes his surprise at witnessing the flocks of them which used to sally out into the streets in the morning twilight, after dry weather succeeded by a shower of rain. It is related that about this period, when the rats increased to a great degree in some small villages in the Highlands, and found it difficult to subsist, they used to creep into the manes and tails of the garçons or ponies, (which were then generally matted and tangled, being seldom subjected to the comb) and in this way were transported to other places, to plant new colonies or find fresh quarters. This mode of conveyance was certainly dexterous and ingenious; but did our readers ever see or hear of a party of rats stealing eggs? The process is this. The roost being discovered and the rats mustered, one of the fraternity, generally of goodly port and dimensions, lies down on his back, and holds the egg within his four limbs, embracing it closely and cordially. His brethren then pull him off by the tail, each taking his turn in dragging the live machine, like the populace at the carriage of a "great man," who, it is probable, may be of a kindred species, the rat species, the rat political. A gentleman in

the country informed us the other day, that he was greatly amused at observing one morning the dexterity and perfect fairness with which a small band of these noxious intruders were feasting in his dairy. A pretty capacious dish of milk had been set out to cream, and the rats, finding the prize, immediately commenced superseding the labors of the dairy maid. One of them stood up against the dish, and another mounted his shoulder in due form, like school-boys preparing to plunder an apple tree. He then whisked his tail over the luscious surface of the bowl, and turning round held it out to his expectant companions below, who stripped it of its milky treasure. This was repeated for some time; then another took his place, occasionally shifting the position, and after they had all skimmed the dish and regaled their senses, they scampered off in the morning sunshine to burrow in their holes and corners.—*Inverness Courier.*

SOUND.—Of all kinds, it is ascertained, travels at the rate of 13 miles in a minute: the softest whisper travels as fast as the most tremendous thunder. The knowledge of this fact has been applied to the measurement of distances.

Suppose a ship in distress fires a gun, the light of which is seen on shore, or by another vessel, 20 seconds before the report is heard, it is known to be at the distance of 20 times, 1,142 feet, or little more than four miles and a half.

Again, if I see a vivid flash of lightning, and in 2 seconds hear a tremendous clap of thunder, I know that the thunder cloud is not more than 700 yards distant and should instantly retire from any exposed situation.

THE WIFE.—That woman deserves not a husband's generous love who will not greet him with smiles as he returns from the labors of the day; who will not try to chain him to his home by the sweet enchantment of a cheerful heart. There is not one in a thousand that is so unfeeling as to withstand such an influence, and break away from such a home.

JOY AND SORROW.—As the most luxuriant plants thrive best with an equal mixture of sunshine and shade, showery dry weather, and in a soil composed of sand as well as richer materials, mingled in due proportions together, so the human mind is a plant which thrives best with a just proportion of prosperity and adversity, joy and sorrow.

GLORY.—Pliny gives the following character of true glory—"Doing what deserves to be written, and writing what deserves to be read; and rendering the world happy and better for having lived in it."

The editor of the Northampton Courier tells of a silken thread eighteen hundred feet in length, wound without breaking from a single cocoon.

[No. 30.]

N. E. FARMER.

Roxbury, Mass., Jan. 20, 1840.

THE EDITOR OF THE N. E. FARMER:

DEAR SIR—Below I hand you a communication addressed to *Elias Phinney, Esq.*, of Lexington, Mass. May I ask a place for it in your columns? Believing the agricultural community will be benefited by the reply, I have preferred this course instead of confining the matter to a private correspondence.

I am your ob't serv't, G. P. B.

HAY TEA FOR SWINE.

ELIAS PHINNEY, Esq.:

MY DEAR SIR—I should not thus publicly have addressed upon you for any information which your experience in swine breeding might suggest, for the fact that your liberality is no less prodigious than is your opinion in these matters worth of credit.

Within the last two or three years, I have bred and raised a considerable number of hogs, but, within the last few months, I have been among unbelievers touching "improved breeds" so called, and which are now circulating so much more generally than heretofore in our country. In September last, my attention was arrested by the picture representation of a Berkshire hog, at the end of an advertisement in one of our agricultural publications—the picture of which pleased me so much that I determined forthwith to try them. I purchased at your establishment two sows of your title and well known Berkshire and Mackay—I obtained a pair of Chinese sows out of my old stock—my Berkshires were from the stock of N. Bennett and others—and in the early part of November last, my establishment consisted of fifteen breeding sows of the Berkshire, these, Berkshire and Mackay, and other crosses, together with two Berkshire boars, and one large pair, Berkshire and Mocha boar. As occasion required, I tried various experiments with these sows, and, in most cases, was pleased with the results.

Towards the latter part of December, 1839, a picture entitled the "American Swine Breeder" was published. Amongst the variety of articles recommended therein as food for swine, I noticed that Mr. Saunders, of Stroud, Gloucestershire, England, made use of *hay tea* with much success. This man had fed a stock of four hundred head of swine, and in the course of his experiments used 1500 hogheads of the wash—maintained them upon a very low rate of one penny per day—many of them were fit for the butcher," &c. &c. Economy of food for swine being among the first considerations with me, I forthwith adopted the use of it. The kinds of hay recommended were, clover, sainfoin, and meadow hay. I purchased a large quantity of each, and commenced the experiment. In the outset I used clover alone. I used herdsgrass, but did not use any of the

meadow hay. Instead of using clear water, (as I had been used to do,) I mixed the food with hay tea (made after the directions advised in the work above named,) and fed it out in all respects as I had done previously, indiscriminately to breeders, store hogs, shoats, pigs and all. The tea was made not simply by my direction, or under my supervision, but by my own hands.

"It deserves particular attention," says Mr. Saunders, "that in a week or fortnight after I commenced the experiment, the pigs improved in their coats, which, from looking coarse, assumed a gloss, and became fine and short, a *proof surely*, of the great nutrition of the food, and of its perfectly agreeing with the hogs," &c.

It deserves particular attention (*say I*) that in a week or fortnight after I commenced the experiment, the pigs *did not improve in their coats*, or in any wise whatsoever—"a *proof surely*," at least, that "the great nutrition of the food" exhibited itself rather differently in the case of Mr. Saunders, than it did in mine, as the sequel will show.

From the first week after I commenced using hay tea—breeders, shoats, and pigs—all began to decline. My large sows were all with pig, and some of them considerably advanced in pregnancy. I took the usual precaution, and commenced physicking—still feeding them on food mixed with hay tea, however, (not suspecting evil *then*), but, despite of all my care, two of my Berkshires "popped off." Upon opening them, I found the lower intestines completely clogged, the lungs spotted and inflamed, and upon the liver appeared small bilcs or pustules. Still I did not charge it to the hay tea, and still I fed them as before. My Chinese sow, *Blue Belle*, suddenly looked languid, and, for a meal or two, refused to eat. I changed her food and mixed a dish of meal, well warmed, with a portion of salts and sulphur, which I placed before her. She would not eat. She was in the sixteenth week of her pregnancy, and being very heavy, I did not attempt forcing any thing down her throat, lest I should kill her young, and thereby, probably, lose the mother. I accordingly left her to herself, in a dry, warm pen, for the night, and in the morning found her dead. I opened her, and found her lungs and liver affected, as was the case with the others, but particularly like those mentioned before, with regard to the *intestines*—the latter being, as it were, *tied up into knots*—so badly clogged as they were. Here was also a loss of *twelve pigs*, out of a fine Berkshire boar as can be found in the State. Still, I did not attribute it to *hay tea*.

Heretofore, my hogs had been fed upon squashes, potatoes, and my refuse cabbages, beets, carrots, &c. &c., together with an occasional mixture of ruta бага and house offal, all of which was thoroughly boiled and mixed before being fed to them. These kinds of food having become exhausted, I commenced more lately with ruta бага and sugar beets, (an equal quantity of each,) boiled together, mashed and mixed up with the hay tea—prepared as before. A pair of fine sows, of the Berkshire and Mocha breed, showed symptoms which led me to fear that they were to be the next victims.—

I physicked them thoroughly, but to no purpose; one died, the other I killed, to *save its life*—or rather its pork. The choice Mackay sow I purchased at your establishment last fall, next refused her food. She was exceedingly fat, and I gave her the knife, in season to prevent her dying of her own accord. I will here remark that *all of these* were affected precisely like those which died first, except that in these last cases, the *livers* appeared very much worse than did those of the first, being in two cases *completely covered* with these hard, viscid-looking bilcs, which must necessarily have destroyed them in a day or two longer, had they been left to themselves.

A young boar, out of a fine Grass sow in my possession last summer, promised well, and I purposed raising him, for his stock. At three months and a half old he shared the same fate with the rest, from the same cause, if I could judge from the symptoms exhibited during his sickness. It appeared that, uniformly, the pigs died within forty-eight hours after the first signs of indisposition. In this last case I had the boar placed alone in a new, floored pen, where I could watch the effect of medicine upon him. He would not swallow voluntarily, and I prepared a dose of castor oil and sulphur, which I forced down his throat at night. In the morning I could find no proof that the physic had operated and accordingly I had him tied up and poured about a gill of lamp oil down his throat. After waiting eight hours, and finding it produced no effect, but that he still declined, and had become rather stupid, I bled him in the feet, which for a while revived him. Towards evening, as a last resort, I attempted the use of *mercury*. Having obtained four pills of ordinary size, I washed them and tried to force them into his stomach: it was *no go*, however. We tied him up again, but he appeared in great pain, and died before we could get the last dose into his mouth. Upon examination, I found his intestines knotted as in the previous cases, and not a particle of the medicine administered the day previous, had passed these knots.

"*Blind Nancy*," my oldest and best breeding sow, (originally from your establishment,) of the Berkshire, Mackay and Mocha breed, gave me eleven pigs on the 22d of December last, ten of which I found dead in her pen. Whether they were born alive or not, I am unable to say, but I am inclined to think they were not, as the last one lived only about an hour after its birth. Nine of these pigs had been purchased by different gentlemen in my neighborhood, at \$10 each, "to arrive." This animal being a very superior one, I felt anxious to save, and of course spared no care or attention necessary to effect it. I had the satisfaction to find that she experienced very little apparent inconvenience from the loss of her fine brood, but, on the contrary, did well after her *accouchment*, upon a slight allowance of *dry food*. In ten days afterwards, I commenced feeding her as before, upon vegetables mixed with hay tea. On the 11th of the present month, she left her food in the trough, for the first time since I owned her, (being naturally a very hearty feeder,) and began to act suspi-

ciously. I tried physic again, but to no effect, and fearing to run the risk, after losing so many, I placed her most reluctantly, in the hands of the butcher. Her lungs were uncommonly purple, and her lower intestines were in the same condition as we had found the others.

My Chinese sow "*Plentiful*"—a fine breeder, from stock originally imported into Salem—from the 15th of this month, dropped twelve pigs (out of my Berkshire Boar) every one of which *came* dead; and from present appearances, I fear the mother will soon follow.

Thus you see, sir, I have met with several severe losses, and I cannot conceive but *the* cause of all these misfortunes is the same. The object, therefore, of this communication is *not* to assert that hay tea has killed my hogs (although I have abandoned the use of it, at least, for the present) but simply to state facts, and enquire of you, whose opinion in regard to this subject will be authority, whether or not it is probable that the astringent powers of the article herein named, (hay tea) are such as would produce these disastrous results; and, if not, what the cause can be, judging, as we only can, from the symptoms produced previously to, and the condition we find the body in after death.

Your opinion will greatly oblige one at least, and I doubt not that it will be thankfully received by all the readers of the Farmer.

I have the honor to be,

Your obt^d servant,

GEORGE P. BURNHAM.

For the New England Farmer.

BUILDING STONE WALL.

MR EDITOR—The communication in your last number taken from the Albany Cultivator signed A., informing the public how the New Englanders build their stone wall, will not apply to all parts of New England, however well it may to some portions.

My own practice, and that of others as far as I am acquainted is, after a layer of small and rough stones 8 or 12 inches in height (which by the way are all, if not more, placed below the surface of the ground) to place next a layer extending across the width of the wall, and upon these "a double row on each side of the wall 12 or 15 inches high," or, as would be better understood by one unaccustomed to the business, a single row on each side, forming a double one, and then go on to complete as A. said, by laying stones across so as to bind together the two sides, reserving smaller, but good shaped ones for completing the top of the structure. To place no stones across till it is raised 24 or 30 inches above the surface of the ground, if it is practised, as very probably it may be in places where stones are less abundant than in this region, is not the way to have a wall durable. A wall 3 1-2 or 4 feet high from the surface, should have at least two binders, that there may be no bulging out of the sides.

The writer of the article referred to, advises to plough about three furrows on each side of the wall to form an embankment against it, and thus by keeping out the frost, effect the standing of the wall upon his small stones of two feet in height. I take his word for it, that wall thus built and banked has stood the test of time.

And would he have these banks in his pastures,

mowing and plough-fields? No serious objection in a pasture that I know of: but in a plough field what would they be but waste ground, where bushes and briars would soon take possession, and as neither plough nor hoe would be likely to meddle, lest the wall lose its supporter, they would soon send their long and penetrating roots to the face bed of mould under the wall, and truly refuse a departure unless the building be torn from over their heads. In a mowing field they might not fare as well, for the scythe coming so near, they would probably get clipped unless the mower should be afraid of dulling his implement. No neat farmer would wish to have this balk left unmowed; and to get over it, together with the trench from which it was taken, every one could not do with ease and comfort, especially when in a hurry as haymakers are prone to be.

I would recommend to this gentleman, and others that have not already adopted the course, before commencing the wall, to remove the soil, (which is easily done with a plough) the width they desire to build. If the land be wet, let the earth be removed to the depth of from one to two feet; in this case middling sized stones should be used to fill. If the land be dry, small stones can be put in promiscuously, but upon them large stones the width of the wall should be placed, and a wall built upon these, I can say with A., "will stand the test of time."

There are many advantages in this course aside from the durability of the wall; you will remove from the farm a great incumbrance. On many farms there are vastly more small stones than can be worked into a wall above the surface, and to what better use can they be put than to bury them beneath? I have seen farms, where in the corners of the plough-fields there were heaps of from one to two hundred loads, at the same time all the occupants' walls laid right upon the surface, reeling this way and that.

Another advantage; there is nothing left under the wall for bushes and briars to live upon; of course they will not be troublesome.

But a still greater advantage; the soil thus saved is more in quantity and of greater value than most of my brother farmers who have not tried it would suppose. Allowing it to be taken off but three feet wide, every five and a half rods in length will furnish the surface of one square rod, and 880 rods in length, an acre;—if it be taken but six inches deep there will be 450 loads, in a cart of large dimensions. And to bank the wall as advised by A. double that quantity would be lost and worse than lost. To yearly cover with this soil the yard where cattle are wintered and during the nights of summer are kept, if the yard be rightly constructed, will retain the excrements of the cattle and with the additional labor of ploughing it once in two or three weeks during warm weather will become a fine top-dressing for grass, which no farmer having once tried, will feel that he can do without.

Nor do I agree with the writer in thinking there is no beauty to a stone wall. But if the stones are piled together without any regard to appearance, then no wonder that there is a want of beauty. There are comparatively few stones that cannot be laid to look well, and still be placed in such a manner as to give firmness and strength to the wall.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Jan. 11, 1840.

Mr James Leonard, of Taunton, exhibited specimens of the Burgonmaster Pear, (so called in this vicinity) a great bearer, and one of the most profitable fruits for the market. We take this opportunity again to repeat, that this is not the true European Burgonmaster, and have but little doubt but that it may prove to be the "Monsieur le Cure," of the European Pomological authors, and probably be identical with the Saint Lezin of the new edition of Duhamel, to which we refer.

Mr Manning exhibited the Bellflower Apple (Coxe No. 32); Winter Orange Pear (Coxe No. 37), and Beurre Sutin Pear. The scions of the last were received from Dr. Van Mons. The tree bore for the first time, this season, and promises to be a great bearer, and the fruit high flavoured and excellent.

Mr Warren exhibited beautiful specimens of the following Apples:—Rhode Island Greening, Roxbury Russet, Nonsuch, and two baskets of a new seedling, which has the character of a fine apple late in the season.

Mr D. Saunders, of Rowley, exhibited a basket of the Minister apple from the original tree, on his farm in Rowley. They were not so large as usual and had been kept too long to support their reputation of a first rate fruit, which they undoubtedly deserve. For the Committee,

ROBERT MANNING.

From Hovey's Magazine.

ON THE CULTIVATION OF CELERY.

As good celery is always sure to meet with ready sale in the market, and commands a liberal price when found there, I propose giving a few practical remarks on the necessary treatment required from the first sowing of the seed in the spring to the taking up of the roots, in the autumn for use. In the first place, be it remembered, that the writer of this does not claim any greater knowledge than that possessed by gardeners and others who have had experience in the cultivation of celery; but as this article may meet the eye of those persons who have not acquired the requisite knowledge to grow it to perfection, it is probable that they may glean something from it, that may be of some assistance to them.

There are six or eight varieties of celery cultivated, and all those who cultivate it, have their favorite kinds; nevertheless, I will venture to recommend the white solid, and the rose-colored solid celery, to be grown, either for the market or for private family use. The second week in April, there is a cucumber frame at work, prepare two or three shallow boxes, and fill them with a fine rich soil, and sow the seed on the surface, with a liberal hand; then press it down pretty solid, with a piece of board, and cover it lightly with very fine sifted earth; this done, give the whole a gentle waterin and place the boxes in the frame, close to the front.

When the plants make their appearance, give them air every day, if possible, by propping up the sash, at the front, where the boxes are placed. As soon as it is perceived that the plants have the least tendency to grow weak, they must be removed from the frame, immediately to the open air, choo

T. S.

some well-sheltered spot. On the approach of winter weather, they may be removed to some place sheltered over, and taken out again after the unfavorable weather is over. If no frame, as spoken of at hand, sow the seed on a rich moist piece of ground, the last week in April, in a sheltered situation: the ground must be well enriched for this purpose, and the older the manure is, the better. It over, and rake the surface very fine and even; then sow the seed pretty thick, on the surface, and with a clean spade beat it lightly down, and even, and cover it over, about a quarter of an inch, with fine soil.

As soon as the plants are about two inches high, they should be transplanted into a nursery bed—but previous to this, the ground must be well manured and dug over; then lay a board on the ground, in order to stand upon, and set the plants out in regular order, at least three inches apart, plant from the nursery. Some may think this last process too much labor; but I can assure all who have such a plan, that it is a process indispensably necessary, and the utility of it will be presently seen. When the plants are taken up from the seed bed, before sowing to transplant them, do not neglect to cut off all the side shoots, which it will be seen, by making their appearance around the base of the plants, and cut off the end of the roots, if desired to produce first rate celery.

About the first or second week of July, the plants should be ready for the final planting out—their growth, robust appearance, by this time, I imagine, will give great encouragement to the grower, to go on and end the good work; but, on the contrary, if the plants had not been removed from the seed bed, I have advised, what a miserable appearance they now make! so much so, that the stems are too weak to bear up the tops, now that they are singly, they would lie flat upon the ground. In this is the case, the remedy is, to cut off the top and leave three or four naked stems sticking upright to disgrace to any person who has the least objection to its cultivation. The plants being so small, it will be found necessary to shade them from the sun through the middle of the day, for some time, until nature has made a fresh effort, and the plants start to grow: not so with those that have been transplanted; for, by removing them to a trench on a damp day, they will scarcely be changed. This is the gain—for whilst the plants will require shading and nursing, these will require a rapid growth; and, however well the plants are nursed, it is rare that they ever produce such good heads as those that receive no

the cultivator has a peat meadow, that is at all overgrown with water, he will find it the situation of any, for the growth of celery; but if there are but few, comparatively speaking, who have such facilities, the next best location would be where the soil is deep and moist, with the subsoil deep. One sure guide to go by is, always to choose the deepest moist soil, whatever the sub-soil may be; it matters not however rich the ground is with manure; if there is a deficiency of manure the growth will be stunted.

In preparing the trenches for the final planting, the soil is deep, dig it out to the depth of eight inches by fifteen inches in width; and the trench as far as is thought proper for the number of plants; six inches of the trench must be filled with the best old rotted manure that can be had; as long strawy litter is not suitable, it

should never be used. After the manure has been thrown into the trench, it should be dug over, in order to mix the soil at the bottom of the trench thoroughly with it; this done, cut a little of the soil from each side of the trench, for the purpose of covering it about an inch, and it will then be ready for the plants, which should be set out six or eight inches apart, in a straight line, down the centre.

Keep the celery free from weeds, and earth a little, at different times, till the trench is nearly filled up; then earth it up no more, until it is done for the last time, which should be the first or second week of September, or sooner, if necessary. I have two reasons for following this process. The first is, that the roots of the plants are already covered as much as they ought to be, if we suppose the sun and air has any effect on them, or is of any benefit to them. My second reason is, that the celery will make a stronger growth, and will be very much superior, both in size and quality, to that which is earthed up every week or ten days, as is generally done. Good celery ought to be solid, thoroughly blanched, and of large size, and perfectly clear of any blemish, such as rust or canker.

Yours,
J. W. RUSSELL.
Mount Auburn, Cambridge, Dec., 1830.

MAKING BACON.

Bacon is an article of use in nearly every family in this country, yet very little attention is paid to its preparation by most of our farmers. It is enough for them that the hams are taken out, salted at random, smoked in an imperfect manner, and this is then called Bacon. The western part of Virginia is most famous for its fine bacon, and those at the north who have in substance adopted the mode pursued there, find their bacon greatly improved.

Too heavy hogs are not as good for bacon as those that are smaller, if equally well fattened. One that will weigh two hundred is large enough, as the salt will strike through the pieces more equally, and the smoking be more perfect. It is essential for the first rate bacon, that the pork should be corn fed; at least if any thing is used in fattening, it should be in the first part of the time, and corn be given for five or six weeks previous to slaughtering. The pork of corn fed pigs will be hard and compact, and the kidney-fat instead of being soft and unctious like lard, will be solid like beef suet.

In the best establishments for making bacon, three pecks of salt and one pound of saltpetre are used for every thousand pounds of pork, the salt to be measured and the saltpetre reduced to powder, thoroughly incorporated or mixed with it. None but the best salt should be used in making bacon. At the south, that which is produced at the Kenhawa works, at the first crystallization is preferred; at the north, the coarse salt of the Onondaga works, or that produced by evaporation, is to be chosen as more pure than any other kind.

The prepared salt is to be thoroughly rubbed on the meat, and then liberally sprinkled over the outside. There is little danger of over salting from quantity; it is length of time that produces the result. The meat is to be laid with the skin side down in good casks, the hams and shoulders first, and then the smaller pieces. Salt must be sprinkled over the bottom of the cask before the meat is laid in. At the fourth or fifth day the meat must be taken up and again thoroughly rubbed with salt. At this period of the process, some use a tea spoon-

ful of powdered red pepper to each piece, and the whole is replaced after any bloody or impure brine that may have formed in the cask is removed. In about two weeks, the smaller pieces will be fully salted, and should be taken from the cask, and the remainder repacked, those that were at the top being now placed at the bottom, as pressure will prevent the passage of the brine through the meat, if the position of the pieces is not changed. The shoulders will be struck through in about three weeks, and the hams in four.

Smoking is the next important part of the business, and should be well done, or good bacon cannot be made. Smoke houses are usually too small; the meat hangs too crowded and too near the fire. The pieces should by no means touch the wall or each other, but space for the free circulation of the smoke should in all cases be allowed. The time required for smoking is the same as that for salting—four weeks for hams, three weeks for shoulders, and two weeks for the other pieces or middlings. Damp weather is improper for smoking meat, as the bacon, from the dampness that is apt to settle on the meat, acquires a bitter flavor in some respects like that given by pyroligneous acid. Sound maple chips, or blocks of hickory wood, are chosen for smoking meat, though the celebrated Hamburg hams are smoked with oak wood alone. The smoke-house should be at a moderate temperature, as that will greatly assist in preventing the appearance of dampness on the meat. Two fires a day, if properly made, will finish the smoking in the time specified above. Some throw occasionally powdered red pepper on the fire, as it is said to prevent the attacks of insects on the bacon after smoking, and somewhat improves the flavor.

If the smoke-house can be kept perfectly secure against the entrance of insects, and is dark and cool, the bacon may be left in it till wanted for use. But there are few houses of this description; and on the approach of warm weather it must be taken down and packed away secure till required for the table. Salt, clean hickory ashes, or oats, will secure it from insects or dripping, if placed in a dry and cool position. The best mode of preserving hams is to pack them down in powdered charcoal, which will not only effectually exclude all insects whatever, but by keeping the meat dry, and correcting any tendency to unpleasant flavor, keeps the meat in good order for any length of time.—*Genesee Farmer.*

Improved method of training Raspberries.—Cut out all the weakest shoots, so as to leave only about six on a stool; then twist the point of one shoot from one stool with one shoot from the stool adjoining, so as to form an arch. Do the same with two other shoots of each plant, so as to form a triple arch between plant and plant, in the direction of the rows, all through the plantations; the space between the rows being left open as usual. The plants should be six feet apart every way. The fruit produced by the trained canes will be fully exposed to the direct influence of the sun and to that of the air, and there will be more room for the suckers.—*Floricultural Cabinet.*

It is easier to die without the thought of death, than to think of death without the apprehension of danger.—*Pascal's Thoughts.*

To be great is not in every one's power, but to be good is in the power of all.—*Cato's Letters.*

From the Journal of the English Agricultural Society.

PRESENT STATE OF THE SCIENCE OF AGRICULTURE IN ENGLAND.

(Concluded.)

There is another point connected with cattle, on which the extension of our present knowledge, as practised in the northern districts, and inquiry as to the possibility of further improvement upon those practices, appears extremely desirable: this is the feeding of stock. In our southern counties the arable farm is kept in heart chiefly by the manure of the sheep flocks, such flocks indeed as no arable farms can produce; but in this country. The beasts kept during winter in the yard, sometimes poorly fed, and only not losing condition, trample the straw until it has the appearance, though it often possesses little of the virtues, of dung. On well-managed northern arable farms, on the contrary, the cattle are tied up in the yard to be fattened, and are fed not only on turnips, but on large quantities of oil cake, purchased at the expense often of many hundred pounds by the farmer. Now it is well known that the better the beast is fed, the more valuable is the manure produced, and that by oil cake in particular its fertilising power is almost doubled. Interesting experiments have been made at the instance of the Highland Society, with a view to ascertain the relative value of food in the stall-feeding of cattle; but much remains doubtless to be cleared up by experiments yet to be made.—It may even be worth inquiry whether, on farms where fattening of stock is largely carried on, a somewhat harder course of cropping might not be permitted, without fear of impoverishment to the land. Peas, for example, and on some ground, potatoes, are a scourging crop; but if the peas, instead of being carried to market, are given to the farmer's stock, it may be a question whether the superiority of the manure may not more than compensate to the farm the previous loss of condition which the crop has occasioned. On this subject of feeding, it is impossible to pass over that heavy article of the farmer's expenses—the keep of farm horses. Here, however, it will be sufficient to make a short extract from the printed report of a club of practical farmers, who have for some time met at Harleston, in Suffolk, for the excellent purpose of discussing doubtful points of agricultural science. It will not be useless, however, first to give a list of the subjects which they had selected for the last year's inquiry, since it shows the spirit of improvement which is at work in the agricultural body.

“On the use of saltpetre as a manure.

On the management and cheapest method of keeping farm horses.

On spade husbandry.

On the best method of improving neat cattle in the district.

On shoeing horses.

On stall-feeding.

On the best method of keeping farming accounts. Whether or not it is beneficial to consume by stock any part of the straw the produce of the farm.

On chaff cutting.”

With respect, however, to our immediate subject, the Report of the Harleston farmers, as it stands in the ‘Mark-Lane Express,’ Feb. 11th, runs as follows:—“Your committee, in common with

every member of the club, was astonished to find that, amongst a body of farmers, all residing within four or five miles of the place of meeting, all using a similar breed of cart horses, and cultivating a similar description of land, such an astonishing difference in the expense of maintaining their cart horses should exist, amounting, in authenticated statements, to upwards of 50 per cent, whether estimated at per head for each cart horse, or per acre for the arable land.” That is to say, not only, with an equal number of acres to plough, the horses of one farmer cost twice as much as those of another; in which case the difference might arise partly from the different number of working cattle maintained; upon which a second question would arise—which farmer had too many, or which had too few?—but also the very same number of horses stood in to one farmer at double the expense which they did to the other. “What greater proof,” the Harleston committee very properly ask, “could be required of the necessity for discussion? and if no other subject had ever been brought before your club, we are of opinion that by debating this question alone it would have rendered incalculable benefit to the neighborhood; for what member, who now learned for the first time that his neighbor was cultivating his land at much less cost than himself in one of the heaviest items in a farmer's expenses, but would go home and improve on his farm management?”

It appears then, even from the superficial survey contained in these few pages, that the practice of farmers varies greatly in different parts of this country, on points where there is no question which practice is best. But it appears also that there are innumerable points of farming on which no one ought to give a positive answer, because no certain knowledge exists. How then is such certainty to be obtained on a matter which involves so large a national profit and loss? Surely, as in other sciences, by careful observation and well-considered experiment. But in many sciences this process, however difficult, is at least within the reach of every inquirer. The chemist requires but a room in which to set up his furnace and evolve his gases; not so the agricultural inquirer; he requires a large farm (for a small one would be insufficient), and a large capital, too, practically engaged in its cultivation. Neither would one farm be sufficient, since the results of its treatment would apply to one soil only, and subsoil, one climate and elevation; whereas there are, even in this country, many soils and subsoils, climates and elevations; and it can scarcely be expected that, either by individual or by public means, such farms should ever be provided in such number. Still, we wish, as agriculturists, instead of uncertain local rules of practice, unknown beyond the districts in which they are severally handed down, to attain the knowledge of general certain laws, not less certain because liable to many equally certain local exceptions,—that is to say, if we wish to raise our important art to the rank of a science, this difficulty must be overcome. After all, however, it is not a difficulty with which we alone have to cope. On the contrary, botany, geology, and other sciences which might be named, depend equally upon the collection of numerous minute facts, by individual observers, over a large surface, even that of the whole globe. But it has been found, in these and in many departments of knowledge, that by the formation of permanent societies, having the promotion of the particular science for their special object, great progress has

been attained. Such a society, by bringing together men who are already desirous of a common end, encourages their zeal, and attracts other laborers into the field. It also regulates their endeavors, as their mutual intercourse shows them more clearly the points of doubt which particularly require to be cleared up. Further, such a society, as it spreads forth its branches, provides a scattered but disciplined host of observers and pioneers. Lastly, the facts thus obtained are recorded, and gradually accumulate, until, by careful comparison of the points in which they agree, some general rule is discovered; and, of those in which they differ, the exceptions are also found, and the causes of those exceptions. It is thus that geology has grown into a science within the present century. It may be said, indeed, that the labor of observation on so minute and extended a scale is great, and the prospect of practical improvement, at best, problematical. It might be asked, in reply to such spiritless objections, why agriculture should be the only science in which patient pursuit of knowledge found no reward?—or whether, while the philosopher, from mere love of science, seeking, for instance, to learn the fixed causes which govern the most changeful and seemingly accidental of all natural things, notes down daily, from year to year, the shiftings of the wind and the rise or fall of the weather-glass, hoping that at last he may be able to arrange these endless vicissitudes under some regular system, and thereby know of a certainty the signs of the sky,—we, the owners and occupiers of the land, on a matter wherein we have a strong interest, in which the whole nation, as consumers, and many millions as laborers, have an interest also, on a matter too in which so much improvement has been long ago made, so much is still making, and so much is in prospect, should alone be so faint-hearted, or so short-sighted, as to doubt that, by our combined exertions, the bounds of our own science may be enlarged; and that, besides this hope, which is sufficient for the followers of other sciences, we may at the same time advance our own interests, give more bread—not to our loss, but with our own gain—to our dependent workmen, and strengthen at the same time the country's resources?

But such arguments are not needed. On the contrary, there are proofs on all sides, whether in the weekly increase of this society's numbers, in the local societies which are springing up in every county, in the farmers' clubs which are being formed, the new machines which are invented, new manures, and new varieties of seed which are announced—above all, and practically, in the improving face of the country; which show that the British farmer is not liable to the charge of being blindly attached to ancient practice, but is ready, with the caution however which befits a man whose livelihood is in agriculture, as well as his pleasure, to adopt improvements in his art, and even to seek for them—that the spirit of inquiry is afloat—that this Society is formed therefore in an auspicious time, and does not represent the wishes of those whose whom it seeks to unite in the road of knowledge, which they are already disposed to pursue, and that its exertions will be engaged, not so much in stimulating as in methodizing the general desire for improvement. How we may best combine and order the separate efforts of our individual members on the details of whose exertions, duly combined, in the various paths of our diversified art, to a common end, and carefully and honestly made known

our body, our slow but steady progress will mainly depend—must form the future subject of our common consideration.

From Youatt's Treatise on Cattle.

THE LONDON DAIRIES.

[Continued.]

Rhodes's dairy has been established more than twenty years, but some of the same family or name lived in that neighborhood nearly a century. Mr Rhodes, farmer, near Islington," is referred to by Dr Brocklesby, in his treatise on the murrain which prevailed among cattle about the middle of the last century. The writer of 'London Dairies,' the British Farmer's Magazine for February, 1811, gives a description of it, of which the following is the substance: The surface on which the buildings are placed, is a gentle slope of two or three acres, facing the east. The sheds run in the direction of the slope, as well for the drainage of the gutters as for the supply of water for milking, which will thus run from trough to trough the whole length of the shed. The sheds are twenty feet wide; the side-walls being about eight feet high, with rising shutters for ventilation, and a row of glass let into iron frames for light. The roof is nearly flat, with a gutter along the centre, a row of stalls, each seven feet and a half wide, and the sides, and adapted for two cows, which are attached by chains to a ring that runs upon an iron rod in the corner of the stalls. A trough of the ordinary size of those used for water is placed at the top of the stall. Four of these sheds are placed parallel and close to each other, and in the party-walls are openings a foot and four feet high, opposite to each cow.—The bottom of these openings is about nine inches higher than the upper surface of the troughs, and contains a one-foot square cast-iron cistern, which serves as the water for drinking; each cistern serves for two cows that are placed opposite to each other, and in different sheds; all these cisterns are supported upon one large tank. These cisterns have a wooden cover, which is put on while the cows are milking their grains, to prevent their drinking at that time, and to prevent the water by dropping any of the rains into it. At the upper end and at one of the corners of this quadruple range of sheds is the measuring room, consisting of three rooms, each about twelve feet square; the outer, or measuring room—the scalding room, with a fire-place and a sink; and the inner, or milk and butter room.

At the lower end of the range is a square yard enclosed by sheds, some for fattening the cows which they have ceased to give milk, and the others for store and breeding pigs. The pigs are kept in the casual stock of skim milk which remains on hand, owing to the fluctuations of the demand. The milk is kept in a well, walled with brick and covered with cement, about six feet in diameter, and four feet deep. The milk soon becomes sour, but is then most nourishing to the hogs.—The fattening swine is thought to be the most profitable of the sucking pigs are sold for roasting. The dung in this yard is a deep pit or pond, into which the dung is emptied. There is a stackyard, and pits for roots, straw, and hay: a place for drying chaff, cart-sheds, stables, and every thing which such an establishment can require. The number of cows varies from four to five hun-

The treatment of the cows is singular in some respects. The cows are never untied while they are retained as milkers. Some of them have stood in the stall more than two years. Mr Laycock, on the contrary, turns his cows out once every day to drink from troughs in the yard, and they remain out from half an hour to three hours, depending on the weather and the season of the year. From the end of June until Michaelmas, they are turned into the fields from six o'clock in the morning until twelve or one, and from two o'clock in the afternoon till about three o'clock on the following morning. Mr Rhodes's cows have always water standing in the cisterns before them.

We can readily conceive that, from the want of exercise, and consequent cutaneous perspiration, Rhodes's cows may give a somewhat greater quantity of milk than Laycock's; but on the other hand, when we think of an animal tied in the corner of a stall for twelve, or eighteen, or twenty-four months together, we cannot help associating the idea of disease, or tendency to disease, at least, with such an unnatural state of things; the feet and the digestive system would particularly suffer, and we should suspect a little vitiation of all the secretions and some deterioration in the quality of the milk. We should like to know the comparative state of health of the animals in the two establishments.—The inclination of our opinion would be strongly in favor of Mr Laycock's plan.

The principal food of the cows in both of these and in all the dairies of the metropolis, is grain; and as the brewing seasons are chiefly in autumn and spring, a stock of grain is generally laid in at those seasons for the rest of the year. The grains are laid up in pits, lined with brick-work set in cement, from ten to twenty feet deep, and of any convenient size. They are firmly trodden down, and covered with a layer of moist earth, eight or nine inches thick, to keep out the rain and frost in winter and the heat in summer. A cow consumes about a bushel of these grains daily, the cost of which is from fourpence to fivepence, exclusive of carriage and preservation. The grains are, if possible, thrown into the pit while warm and in a state of fermentation, and they soon turn sour, but they are not liked the worse by cattle on that account; and the air being perfectly excluded, the fermentation cannot run on to putrefaction. The dairymen say that the slow and slight degree of fermentation which goes on, tends to the greater development of the saccharine and nutritive principle, and they will have as large a stock upon hand as they can afford, and not open the pits until they are compelled. It is not uncommon for two years to pass before a pit of grain is touched; and it is said that some have lain nine years, and been perfectly good at the expiration of that period. The dairyman, however, must know his brewer, and be able to depend on him. The grains from a large ale brewery are the most nourishing. Those from the porter brewery are not so good; and those from the little brewers, who first draw off their ale and afterwards extract every particle of nutriment in the formation of table beer, are scarcely worth having.

Each cow is allowed a portion of salt. In Rhodes's establishment it is given with the grains. Laycock salts his rick when it is first made—a most excellent plan, for the hay is not only effectually secured from becoming mow-burnt or mouldy, but it is rendered more grateful to the animal, and we may venture to say, almost doubly nourishing, from the

development of the saccharine principle. It is to be doubted, however, whether the cows obtain a sufficient quantity of salt in this way. Some should be given with the grains.

The grains are usually given about three o'clock in the morning, and two o'clock in the afternoon, being a little before the usual milking hours.—Between the millings they have green meat, as long as the season will permit. Cut grass is a favorite and excellent food; but where it can be managed, the plan of Mr Laycock to let the cows cut the grass for themselves is a far superior one. Tares come in before the grass, and are afterwards given alternately with it. In winter, turnips, potatoes, and mangel-wurtzel, are given as long as they can be obtained at any reasonable price; and then the dairyman is driven to hay or chaff: the superiority of chaff is now generally allowed.

Both of these gentlemen fatten off their dry cows with grains, oil-cake, and clover chaff, to which Mr Laycock adds boiled linseed. Our readers may recollect the experiments made by the Duke of Bedford on the fattening quality of linseed, boiled and unboiled, and in which the simple unboiled linseed fattened the animals more expeditiously than any cooked preparation of that seed. Mr Laycock boils the linseed in a common boiler, and when reduced to a pulp, conveys it by tubes into large wooden cisterns, where it is mixed with clover chaff roughly cut, and sometimes with grains.

These wholesale dairymen usually agree with the retail dealers, that they (the dealers) shall milk the cows. The dealer knows the quantity of milk that he wants, and the dairyman knowing the usual quantity of milk yielded by each cow, calculates what number of cows will meet the demand, and the retail dealer attends at three o'clock in the morning and two in the afternoon, to milk these cows. He carries it into the measuring room, where its precise quantity is ascertained. If, as cows often vary considerably in their flow of milk in the course of two or three days, he has milked more than his quantity, it is put into a vessel belonging to the dairyman; or if the cows should not have given their usual supply, the deficiency is made up from the dairyman's vessel. The milk which is left on hand is put into shallow vessels, the cream skimmed and made into butter, and the skimmed milk thrown into the pit for the hogs.

The joint-stock dairies, which a few years ago sprung up in such abundance, have either ceased to exist, or the number of cows much diminished, have fallen into private hands. While there were many partners, and the business was controlled by a committee of persons who knew nothing at all about the matter, they all proved to be lamentable failures. Some of them, even in the hands of private individuals, who brought with them little or no experience, were sadly ruinous concerns. The Metropolitan dairy was a striking illustration of this; but now, under the management of those who have been drilled into the business, it is doing better.

When a true genius appears in the world, you may know him by this sign, that the dunces are all in confederacy against him.—*Sieff.*

The happiness of every man depends more upon the state of his own mind than upon any one external circumstance; nay, more than upon all external things put together.—*Sir W. Jones.*

number of varieties. Hence we conclude that all limestones are not the same limestones, but that they possess, in a greater or less degree, qualities foreign to their uses for agricultural purposes, and besides they present different degrees of solubility, which render them, more or less subject to detraction and mixture with soils. As in our country, all mineral wealth is found in the hands of the landholder and cannot be wrested from him without his consent to being overreached by sharpers, who are always ready to practise intrigues to the unwary. As all soils derive their qualities from mineral substances contained in them, and possibility of proportion to these qualities, we urge, and in doing it we would cry aloud and spare not, the necessity of every farmer being a mineralogist, and having a net of specimens, which by a few years of care he could collect from every quarter of the globe. His facilities, such accumulations, are certainly great, living as we are in daily communion with rocks and stones, and as he does, an intercourse with every people and tongue under the whole heavens, through which might obtain the noblest specimens and form an acquaintance with every climate.

Mount Osceola, Jan. 19, 1840.

W. B.

LARGE LEMONS.

They have been favored with the sight of a pair of large lemons grown upon one twig, which weigh 2 1/4 lbs.—one of them measures 14 inches round one way and 2 inches the other way. They were raised in the house of Mr Timothy Bigelow, of Medford. The one on which they grew is said to be fifty years old and is buried in the ground. They are the largest and finest lemons we have ever laid eyes upon.

J. B.

BRIGHTON MARKET.—MONDAY, JAN. 27, 1840.

Reported for the New England Farmer.

Market 344 Beef Cattle, and 1085 Sheep.

Prices.—*Beef Cattle*.—Prices obtained last week of quality were fully sustained. A few better cattle at market and higher prices were obtained. First quality, \$6 50 a \$6 75. Second quality, \$6 00 a \$6 50. Third quality, \$5 00 a \$5 75.

Wooling Cattle.—Mess \$5 50; No. 1 \$5 00.

Horses and Calves.—We notice a few sales—\$25, \$23, and \$35.

Wool.—We notice lots taken at \$2 75, \$3 00, \$3 50, and a lot of fine wethers at \$5 00.

Swine.—None at market except a few from the neighborhood.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded dry exposure, week ending January 26.

NOTICE.

Fruit Committee of the Massachusetts Horticultural Society, are requested to meet at the rooms of said Society, Tremont Row, on Saturday next, February 1st, at half past twelve, A. M. E. M. RICHARDS, Chairman.

January 29, 1840.

FOR SALE.

Excellent Farm, pleasantly situated about 20 miles from the city, containing about 100 acres. For full description, see inquiry at this office.

A situation wanted by a man with a small family to live on a farm.

January 30. 4W

VEGETABLE CUTTER.

Willis's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and succulent roots for fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public: they are aware that it has been long wanted and they now offer a machine that cannot fail to give satisfaction upon a fair trial. It will cut with ease from one to two bushels per minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at the Agricultural Warehouse, 51 and 52 North Market Street, December 18.

JOSEPH BRECK & CO.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO. at the New England Agricultural Warehouse and Seed Store, Nos. 51 and 52 North Market Street, have for sale, Green's Patent Straw, Hay and Stalk Cutter, operating on a mechanical principle not before applied to any implement for this purpose. The most prominent effects of this application, and some of the consequent peculiarities of the machine are—

1. So great a reduction of the quantum of power requisite to use it, that the strength of a half grown boy is sufficient to work it very efficiently.
2. With even this moderate power, it easily cuts two bushels a minute, which is full twice as fast as has been claimed by any other machine even when worked by horse or steam power.
3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.
4. The machine is simple in its construction, made and put together very strongly. It is therefore not so liable as the complicated machines in general use to get out of order.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone, and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and no charge for casks or carting.

Also, ground Oyster Shells

Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No 52 North Market Street, or through the Post Office will meet with prompt attention

NAHUM WARD.

SCIONS OF FRUIT TREES FOR SALE.

The collection of fruits cultivated at the Pomological Garden consists of more than 1400 varieties of the Apple, Pear, Plum, Cherry and Peach. Scions of all those which have been proved are offered to nurserymen and others. Gentlemen wishing to send collections of American fruits to their friends in Europe can be furnished with most of those of first rate quality. They are warranted true to their names, and are in all cases cut from fruit bearing trees.

Salem, January 24, 1840. ROBERT MANNING.

AMERICAN SWINE BREEDER.

Just published and for sale by JOSEPH BRECK & CO. the American Swine Breeder; a Practical Treatise on the Selection, Rearing, and Fattening of Swine; by Henry W. Ellsworth, price 75 cents.

January 15.

Culture of the Beet and Manufacture of Beet Sugar.

Just published and for sale at the N. E. Agricultural Warehouse and Seed Store, a treatise on the Culture of the Beet and Manufacture of Beet Sugar, by David Lee Child. Price 75 cents.

January 22.

A MAN WANTED.

To do the work on a small place, a few miles from the city. He must understand the cultivation of vegetables, fruits, &c., and the care of horse, cows, &c. A single man, from 20 to 30 years of age, of steady and industrious habits, may inquire at this office.

January 15. J. B. I.

ROHAN POTATOES,

For sale at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at 85 per barrel.

MISCELLANEOUS.

THE WILD FLOWER.

BY J. F. SMITH.

SWEET wilding tufts that, 'mid the waste,
Your lowly buds expand;
Though by no sheltering walls embraced,
Nor trained by beauty's hand:

The primal flowers, which grace your stems,
Ereidst as the daisy's shine,
Found thus, like unexpected gems,
To lonely hearts like mine.

'Tis a quaint thought, and yet perchance,
Sweet blossoms, ye are sprung
From flowers that over Eden once
Their pristine fragrance flung

That drank the dews of Paradise
Beneath the starlight clear;
Or caught from Eve's dejected eyes,
Her first repentant tear.

ETHAN ALLEN IN ENGLAND.

Col. Ethan Allen was a man destined to strike the world as something uncommon, and in a high degree interesting. He was but partially educated and but obscurely brought up; yet no man was ever more at ease in the polished ranks of life than he. Not that he at all conformed to their artificial rules and title etiquette; but that he observed the dictates of natural good sense and good humor. His bearing was in total defiance of fashion, and he looked and acted as if he thought it would be a condescension thus to trammel himself. It is well known that early in life, in his own country, he acquired an influence over his fellow-men, and led them on to some of the most daring achievements. He seemed to have possessed all the elements of a hero—a devoted patriotism, a resolute and daring mind, and an excellent judgment.

His conduct as a partisan officer is well known in this country, and was of great service to the cause of liberty during our revolutionary struggle. He was taken prisoner and carried to England; where his excellent sense, his shrewdness and wit, introduced him into the court region. A friend of our earlier life, who was well acquainted with this part of the history of this singular man, used to take great delight in telling us some anecdotes of Col. Allen, while a prisoner in London. We have before mentioned the firmness with which he resisted the attempts to bribe him from the cause of his country, and the caustic satire with which he replied to a noblemen, who was commissioned by the ministry to make him formal offers to join the British cause in America. The incident is a striking one, and will bear a repetition.

The commissioner, amongst the tempting largesses, proposed that if he would espouse the cause of the king, he might have a fee simple in half of the State of Vermont. "I am a plain man," said Col. Allen in reply, "and have read but few books, but I have seen in print somewhere, a circumstance that forcibly reminds me of the proposal of your lordship: it is of a certain character that took a certain other character into an exceeding high mountain, and showed him all the kingdoms of the earth and the glory thereof, and told him that if he would fall down and worship him, these would all be his; and the rascal" added he, "did at own a foot of them!"

His interview with the King at Windsor is men-

tioned as highly interesting. His Majesty asked the stout-hearted mountaineer, if they had any newspapers in America. "But very few, and these are but little read," was the answer. "How then," asked the King, "do the common people know of these grievances of which they complain, and of which we have just been speaking?" "As to that," said he, "I can tell your Majesty, that amongst a people who have felt the spirit of liberty, the news of oppression is carried by the birds of the air and the breezes of heaven." "That is too figurative an answer from a matter of fact man, to a plain question," rejoined the King. "Well, to be plain," answered the rebellious subject, "among our people the tale of wrong is carried from man to man, and from neighborhood to neighborhood, with the speed of electricity; my countrymen feel nothing else: 'out of the abundance of the heart the mouth speaketh.' I will add, with great respect to your Majesty, that such a people cannot be put down with the sword."

The King made a long pause, as if strongly impressed with the truth of his remarks. At length, changing the subject, he asked Col. Allen if he knew Dr Franklin; and being answered in the affirmative, inquired concerning his experiments with electricity, and expressed a curiosity to experience an electric shock. The British sovereign seemed to take pleasure in the conversation, which he kept up for more than an hour, and at length made Col. Allen promise to visit him with his countryman, Dr Franklin, at his palace in London. Some weeks after this, he was reminded of his promise by the noblemen above mentioned, and an hour was fixed for the homebred philosopher of America to explain the mysteries of a new discovery in science to the royal family. They attended accordingly, and with an apparatus chiefly of his own invention, Dr Franklin exhibited many of those simple and amusing experiments, for which he was so noted, and at which the royal children, even those of a larger growth, were much delighted.

In this playful way, Dr Franklin took occasion to convey instructions as to the properties of this astonishing fluid. While the royal habitation was thus in a most unkingly uproar, the Premier was announced as in waiting. The King seemed for a moment disturbed. "I forgot my appointment with the minister," said he, "but no matter, I will eschew business for once, and let North see how we are employed." Accordingly the minister was ushered in with little ceremony, and it was soon concluded that he should have a shock. Allen whispered to the Dr. to remember how he had *shocked* us across the waters, and to give him a double charge; whether it was designed on the hint of his friend or not, was not ascertained, but the charge was so powerful on the nerves of his lordship, as to make him give way in the knees, at which all, especially the Princesses, were almost convulsed with mirth.

Some of Col. Allen's happy retorts at the clubs and fashionable parties are still remembered and often repeated. On one occasion he was challenged to a glass of wine, by the beautiful Duchess of Rutland, who seems to have been particularly pleased with his independent manner, "and you must qualify your glass with a toast," observed the lady. The Vermont' very unreflectedly observed that he was not used to that sort of ceremony, and was afraid he might give offence. If, however, the lady would be so good as to suggest a subject, he would endeavor to give a sentiment. "O," said

she, "never mind the subject—any thing will do so that it has no treason in it." "Well," says he "this may do for a truth if not for a toast," and fixing his eyes adoringly on the far-famed court beauty, he proceeded:

"If any thing could make a double traitor out of a good patriot, it would be the witchcraft of such eyes as your ladyship's."

The blunt sincerity with which this was spoken together with its exact fitness to the occasion and the person, caused it to be long hailed in the boudoir, as an excellent good thing; and although it had the effect of heightening for a moment the beauty to which it was offered as a tribute, it is said the fair Duchess often afterwards boasted of this compliment as far before all the empty homage she had received from the glittering comboxery of the city.

A lady once sincerely asked Col. Allen, in a large asseably, at what time fashionable ladies in America preferred taking the air. He perceived her drift, and bluntly answered, "Whenever it was necessary to feed the geese and turkeys." "What," inquired the lady, "do the fine women in your country descend to such menial employments?" Allen was always aroused at any attempt to depreciate the fair ones of his own country, and with a good deal of warmth he replied, "American ladies have the art of turning even amusements to account. Many of these ladies could take up the subject of your Grace's family history, and tell you 't the feats of valor and bursts of eloquence to which your ladyship is probably indebted for your distinguished name, most of which it is likely, would be as new to you as the art of raising poultry." The sarcasm produced a deep blush in the face of the fair scoffer, but it procured for the captive and his countrymen an indemnity against court ridicule for the future.

An English gentleman, who had long been suffering with an imposthume, was declared by his physician to be at the point of death. Having bid farewell to his wife and children, he expressed wish to take leave of his servants. One after another they came in, kissed his hand, listened tearfully to his advice and blessing, and bowing low left the room. Last of all came a favorite monkey. He too bowed respectfully, placed one paw in his master's hand, and with the other covered his eyes. At this ludicrous sight, the dying man burst into such a convulsion of laughter, that the imposthume broke, and he recovered.

Cromwell's Skull.—A person visiting a museum of curiosities, was shown the skull of Oliver Cromwell. "It is extremely small," said the visitor.—"Bless you sir," replied the Cicero, "it was his skull when he was a little boy."

Henry VI. being asked why he went so meanly attired, answered, "It becometh a king to exceed his subjects in virtue, not in vesture."

AGRICULTURAL.

from the Journal of the English Agricultural Society.

THE DEANSTON FREQUENT DRAIN SYSTEM,

Distinguished from and compared with the Furrow Draining and Deep Ploughing of the Midland Counties of England. By the Right Hon. Sir JAMES GRAHAM.

A recent inquiry addressed to me by Lord Ceor, relative to the "Deanston frequent Drain System," induces me to believe that I may render service to agriculture, if I am so fortunate as to direct the attention of your readers to this important subject at this particular time.

The great object of our quarterly publication is, to conceive, the establishment of an authentic repository of practical experiments; and by multiplying and proving of this description agriculture will be treated as a science, and will advance, and the transactions of our Society will become the depository of useful information, verified by the name and address of the several correspondents.

Mr Smith, of Deanston, in the county of Perth, was examined as a witness before the Agricultural Committee in 1836. He gave a detailed account of a system of draining, which very much resembles the furrow-draining of the midland counties of England, except that at Deanston, stone being on hand, the drains are made with stones and with tiles; and at Deanston the cover of the drains is 22 inches below the surface; whereas in the counties of Westmoreland and Northamptonshire the top of the furrow is not so deeply laid. Mr Smith, however, his land is effectually drained, lays it down in a furrow: in the midland counties the furrows are carefully preserved.

Mr Smith, after draining, for the first rotation at least, does not bring to the surface any of the subsoil by a plough of his own invention, which is a common plough turning up the surface, he merely turns the subsoil to the depth of 20 inches, and pulverizes the lower crust without turning it to the top. This subsoil plough, such as Mr Smith has used, is a heavy implement, requiring the draught of four, six or eight horses, according to the tenacity and strength of the subsoil.

Mr Smith contends that the subsoil, by being turned up, becomes pervious both to air and moisture; and the efficacy of the drains is thus perfected and secured; and that the character of the subsoil when relieved from superfluous moisture, and of atmospheric influence, is entirely changed; it becomes mellow and friable; and after one or two crops, or a lapse of five years, that it may be brought to the top, by deep ploughing, with safety and propriety, and be mixed with the surface-soil to advantage.

In the midland counties of England, deep ploughing and furrow-draining has been the constant practice; but the use of six horses in a subsoil plough is a novelty in Scotland. In England a

portion of the subsoil is raised at once to the top: at Deanston the subsoil, though broken, is not so raised; and here the important question arises, When land is effectually underdrained, which is the right treatment of the subsoil? Will you bring a portion of it immediately to the surface by deep ploughing, or will you, with Mr Smith, delay this operation for some years, until the subsoil shall have been mellowed, after having been broken and penetrated by the atmosphere?

The advantages of the wide circulation of agricultural knowledge, of the multiplication of experiments, and of the interchange both of theory and practice between Scotland and England, will here develop themselves in the clearest light. Furrow-draining and deep ploughing have been practised in England for half a century; yet the introduction of an analogous system into Scotland is regarded almost as a discovery. But in Scotland itself the greatest difference of opinion prevails on the question of turning up or only moving the subsoil after draining. Some of the greatest authorities in East Lothian differ from Mr Smith, and lean to the English practice. In the first furrow for green crop after draining, by two ploughs following each other, which is equivalent to trench-ploughing, they go down to the depth of 12 or 14 inches, and bring up a certain quantity of virgin soil.

It is obvious that this difference of practice in the treatment of the subsoil involves a most important question, which can only be solved by accurate and multiplied experiments. The outlay of capital, which is common to both plans, consists in effectual underdraining; and no subsequent management, no fresh application of capital, can be of any avail, unless, on retentive soils or a substratum of clay, the water be quickly carried off. This I take to be an axiom undisputed in agriculture: but after effectual draining, when the outlay has been incurred, the mode of treating the subsoil affects only production, and does not involve expenditure; and greater produce without additional outlay is the grand object of the practical farmer.

We have seen that in draining, Mr Smith uses stones, because he has them on the spot. Tiles are substituted in the midland counties of England because stones cannot be obtained easily, and because in the clay districts tiles are cheaply and easily manufactured.

It has always appeared to me that skill in agriculture does not so much consist in the discovery of principles of universal application, as in the adaptation of acknowledged principles to local circumstances.

The peculiarities of soil and climate, what nature gives or nature withholds in each particular district, must be carefully considered and judiciously investigated, before any given experiment, though locally successful, can be pronounced to be generally useful or universally applicable. The neglect of this consideration has brought agricultural experiments into disrepute, on account of the heavy losses which they have occasioned. If the record now opened in these Transactions be faithfully kept, this evil will be averted; for I hope that each

experiment detailed will be authenticated by the name of the party who makes it, and that every local circumstance of a peculiar character will be carefully particularised.

My attention having been thus directed to the various treatment of subsoils after under-draining, I tried an experiment in the year 1838, on a field of about 8 acres of the poorest and wettest land. The surface-soil is about 5 inches deep, of black earth of a peaty quality: the subsoil is a weeping retentive clay; with sand and rusty gravel intermixed. This clay goes down to the bottom of the drains, which are of tile, laid 30 inches deep, in every furrow. This field is in a farm lately taken into my own hands, and was rented by the out-going tenant at 4s. 6d. an acre. It was in pasture of the coarsest description, overrun with rushes and other aquatic plants.

After draining, on one-half of this field I used Mr Smith's subsoil plough; on the other half I trench-ploughed to the depth of 10 inches by two ploughs following in succession: in the first part not mixing with the surface any of the subsoil; in the last part commingling the surface and the subsoil in nearly equal proportions. The whole field was heavily but equally manured and planted with potatoes; and though the potato crop, even on good land, in this neighborhood, was below an average, yet the crop in this field exceeded an average, and yielded about twelve tons per acre. The field is equally drained in every part. I filled up the tile drains with porous materials, such as stones, moor-turf reversed, and tops of thinnings of young plantations, to the exclusion of the retentive clay which held the water. The crop of potatoes was so equal throughout the field, that I am unable to pronounce positively which part was the best; but I am inclined to give the preference to that portion where Mr Smith's subsoil-plough was used. Since the potatoes were taken up, the land has not been ploughed or ridged up, but remains perfectly flat; and I observe, where Mr Smith's subsoil plough was used, that no water whatever, notwithstanding the wetness of the season, has stood upon the land; where trench-ploughing was adopted, and a portion of the clay brought to the surface, after heavy falls of rain the water has stood for a time in hollow places; and here the land, in consequence, would seem to be rather soured. The field will be sown out this spring with oats and grass-seeds, and I shall watch with anxiety the future effect of the past different treatment.

In the mean time I have relet the farm: the outlay in draining and extra-ploughing cost me £6 18s. 4d. an acre; but the field in question, which was

The size of the tiles used was 6 inches for the main drains, and 3 inches for the common drains. The tile drains were laid 10 yards apart.

	£	s.	d.
170 roods of draining, cutting, laying the tiles and upfilling at 4d per rood,	1	3	4

Do. of turf, &c., for covering the tiles, 70			

valued at 1s. 6d. an acre to the out-going tenant, is rented by the in-coming tenant at 20s. an acre on a lease of 14 years.

On a small field of very retentive clay, of an hungry and bastard kind, intermixed with rusty gravel, I tried six years ago the experiment of trenching with the spade after close and careful draining; I buried the surface soil, which was poor and exhausted, and I brought the subsoil to the top from the depth of 18 inches. I limed this land and sowed it out with rape and grass seeds. It has been very unproductive ever since, and all my expenditure upon it hitherto, has been thrown away; for, though dry, it bears no more grass than before the draining. I think, however, that the surface-soil is now mellowed by exposure to the atmosphere; and I am about to break up this field and to put it through a rotation, in the confident hope of increased production. I have also ordered a field of 20 acres of dry and good land, cropped out by a bad tenant, to be treated with a view to this experiment on subsoils. The field lies in two ridges on the bank of the river Esk; the soil is alluvial deposit: on the lower ridge next to the river the surface is a fine loam of 12 inches deep, incumbent on a subsoil of sandy loam 16 inches deep.—On the upper ridge the loam does not exceed 8 inches, but the subsoil is a good clay 13 inches deep; in the hands of tenants up to the present time, the depth of the furrow ploughed has never exceeded 6 inches. I have ordered the lower flat to be trench-ploughed to the depth of 14 inches, bringing the virgin loam to the top: I have ordered the upper flat to be stirred with Mr Smith's subsoil plough, thus breaking the lower crust without changing the surface. The whole is to be manured equally with bone-dust, and a crop of turnips is to be taken.

I shall be happy, at a future time, to communicate the comparative result of this different treatment; and I trust I may be pardoned for my present intrusion, which arises from my anxiety to fix the attention of the farmer on this question of the treatment of subsoil, which by judicious management, I think, may add to the power of production without cost; especially when the surface by long and repeated cropping has been exhausted and has become comparatively sterile. At the commencement of our publication I could not omit an opportunity of endeavoring to use it for the legitimate purpose of inviting accurate experiment, with the view of circulating and extending agricultural knowledge.

I have the honor to be, sir,

Your faithful servant.

J. R. G. GRAHAM.

Netherby, 26th January, 1839.

EDUCATION.—I have ever thought the prohibition of the means of improving our rational nature, to be the worst species of tyranny that the insolence and perverseness of mankind ever dared to exercise. This goes to all men in all situations, to whom education can be denied.—*Lavater.*

EXPERIMENT WITH POTATOES.

MESSES EDITORS.—Farmers are generally aware that the potato is not produced on the proper roots of the plant, or those devoted to nutrition, but on side shoots from the main stem, above the roots proper, and nearer the surface of the earth. It has been stated that De Candolle, taking the hint from this production of the tubers, and conceiving that the shoots still farther from the roots on the main stem if covered with earth, would furnish tubers instead of leaves, actually succeeded in growing them, for considerable distances on the main stems, by repeated coverings of them with earth.—A writer on vegetable physiology, in the Farmer's Register, basing his opinions, it is presumed, on this peculiar law of the plant, recommended the following method as probably the best for the cultivation of that root:

"Let the ground be prepared in the usual way; lay the potatoes in the bottom of the furrow, and cover them to the depth of three or four inches with coarse manure or leaves, and then with two or three inches of earth. After the stalks are six or eight inches above ground, cover all except their ends in the same manner; and perhaps this process may be advantageously repeated a third time: after which they should be suffered to go to seed. The first covering should, unless the land be very rich, consist in part of manure, in order to furnish nourishment to the plant; the second and third may consist of straw or leaves, as the principal object is to keep the earth loose, and protect the tubers from the action of the sun."

In order to test the correctness or fallacy of these opinions, I determined last spring to partially repeat the experiments of De Candolle, and selected for the purpose two hills on my bed of early potatoes in the garden. The ground was highly manured, having the last year been occupied by a mound of manure, on which cucumbers and melons were grown. This was thoroughly incorporated with the garden mould by ploughing, and in this potatoes of the common early variety were planted in hills at the distance of about three feet. Taking a barrel, I sawed it in two in the middle, and placed one half over each hill of potatoes, sinking the rim some two or three inches in the earth; the heads of the barrel of course were out, and the hills were covered in the usual manner by being slightly rounded.

When the plants came up and had attained a height of about ten inches, I filled the half barrels with the same rich mould, merely leaving the tops of the plants in sight. The growth of the plants was most luxuriant, the length of the stems far exceeding those in the same earth near them, and they continued green and flourishing long after the others had ripened and died. At the time of digging, the half barrels were taken away and the earth carefully removed, without disturbing the stems. Not a trace of a tuber was to be found, except on the shoots below the natural surface of the ground, not differing in this respect, in the least from those around them. The shoots that came out above these, from the main stems, showed no disposition to produce tubers, but reaching the surface, rivalled in vigorous growth the original stems. The yield from the hills was a little more than from those around them, owing perhaps to the longer period of their growth, or the greater supply of nutriment afforded by the additional mould.

Whatever may be the cause, my experiment has not resulted as did De Candolle's, in the formation of tubers above the original or first crop, and would seem to add but little force to the arguments used by some in favor of deep hilling, at the second or latest hoeing. A rich friable earth, in which the roots find sufficient nutriment, and the tubers enlarge at their pleasure, and a covering of sufficient depth at the first, would seem to be about all that is required, with a clean surface, for the production of the potato.

H. M. G.

ROCKY MOUNTAIN FLAX.

We know of no plant which seems to better deserve an effort for its introduction into the class of cultivated vegetation, than the one above named. The common flax plant is an annual; is exposed to the depredations of many insects; to get the full amount of the crop it is necessary it should be pulled, and yet with all these drawbacks, it is a valuable crop, and indispensable for many purposes. If a plant possessing the same valuable qualities as the common flax, yet which would be perennial, and could be cradled or mown at maturity—(thus giving an annual succession of crops from the same root)—could be discovered and brought into use among us, and particularly in the fertile valleys and prairies of the western States, the advantages would certainly be very great. Such a plant is the Flax of the Rocky Mountains; and the individual or the society that shall introduce it into cultivation, should it answer present indications, will be considered as benefiting the agriculture of the country essentially. Of the various notices which we have seen of this plant, we select the following as more particularly describing its appearance, and the extent of its growth in those regions.

Mr Parker, in his excellent narrative of his journey across the Rocky Mountains, from the Mississippi to the Pacific, says, "Flax is a spontaneous production of this country. In every thing, except that it is perennial, it resembles the flax that is cultivated in the United States—the stalk, the bowl, the seed, the blue flower, closed in the day time and open in the evening and morning. The Indians use it in making fishing nets. Fields of this flax might be managed by the husbandman in the same manner as meadows for hay. It would need to be mowed like grass; for the roots are too large and run too deep in the earth, to be pulled as ours is; and an advantage that this would have, is, that there would be a saving of ploughing and sowing." This was on a branch of Lewis or Snake river, of the Columbia.

In a late journal of a passage across these mountains, by Mr Oakley, of Illinois, under date of the 21st of July, 1839, occurs the following: "Encamped to-night in a beautiful valley, called Bayou Seward, 28 miles from the head of the south fork of the Platte. It is a level prairie, thirty miles long and three wide, and was covered with a thick growth of flax, which every year springs up spontaneously."

Whether the Rocky Mountain flax will prove to be as near the common flax as is supposed by Mr Parker, may be doubted; but that it is unlike, and far superior, to the two or three kinds of native wild flax that have before been discovered in the United States, would also seem to be clear. A tract of 90 square miles of flax, such as Mr Oakley described, would be a sight in any country, and would rival the grass covered prairies of Illinois.—*Albany Cultivator.*

MUTUAL IMPROVEMENT—CLUBS.

What, we would ask, is there to forbid farmers' noires, or conversations? or, if such words would be considered too much in the fashionable or boarding school style for the farmer, let the word *club* be substituted, and then we shall have farmers' clubs,—meetings we think both desirable and practicable. Intercourse with each other is the cultivators of the soil need, to enlarge their views, diffuse information, promote inquiry, and create a feeling of unity of interest and concert of action, so necessary in all communities. It is the contact of mind with mind that brightens the faculties, and incites light, as the collision of the flint and steel produces the spark and the flame. Horticultural meetings of any kind have a tendency to these good effects: institutes, societies, clubs, all co-operate to the same end, and with different degrees of effectiveness, contribute to the same result.

In England, where the science of agriculture and the means of improving it, are as well understood, to say the least, as in any part of the world, clubs, or neighborhood meetings of farmers for the discussion of agricultural topics, have been found among the most effectual aids the cause of the farmer could receive. That such would be the case in this country, we see little room to doubt; in fact the influence of our county and town societies, furnishes the most conclusive evidence on this point. It may indeed be said that the greater diffusion of agricultural periodicals in this country, renders such meetings less necessary than in the old country, where such papers or books are rare. This may partly be true, but could not these two means of improvement be brought to act together, and thus exert an influence more favorable and more powerful than both acting singly and detached from each other?

The difficulty in originating and sustaining such clubs, has been found to arise from the want of constant interest in the discussions and the paucity of copies introduced. To do away these objections propose the following method. Let the members of these neighborhood clubs provide themselves with a number of the best agricultural publications in the country, each one, if he chooses, making his selection; let these publications be a common stock for the benefit of the members; let meetings be held once a month, at which these publications are to be returned, exchanges made, the various papers found in them discussed, and the practical views of the members, for or against the several opinions advanced, be made known. We can easily imagine that in such case the meetings would be uninteresting or uninteresting. At the end of the year, the numbers of each volume could be collected and bound, and ere long an agricultural library for the use of the club would be established of the most valuable kind. Few individuals are found who are able to procure all the journals in this class they would like to read, nor can any journal embody all the valuable papers and that are furnished for the information of the club. In this way an individual can command the reading, and avail himself of the information contained in the best farming periodicals of this country, without any extra trouble or expense.

In any neighborhood of cultivators be disposed to adopt our suggestion, we may be permitted to recommend, after our own Cultivator, the *England Farmer*, the *Farmer's Monthly Visitor*, the *Maine Farmer*, the *Farmer's Cabinet*, the

Franklin Farmer, the *Yankee Farmer*, *American Farmer*, and particularly *Ruffin's Farmer's Register*, one of the best publications in this or any other country. Of European works, the *London Farmer's Magazine* is the best.—*Albany Cultivator*.

CULTURE OF INDIAN CORN.

MR JESSE BUEL.—As I have been a constant reader of the *Cultivator*, I often find the inquiry from your different correspondents, respecting the best method of raising a crop of corn. I therefore send you a statement of the soil, management and profit of one acre, planted by me with corn the present season.

The soil, two-thirds of it, was a warm gravel; the other third was low, wet, and covered with rushes and wild grass, with a very tough sod; but I was careful to put two good underdrains through it, which left it a rich black mould. About the 1st of May I drew twentytwo loads of unfermented manure, each load containing thirtyfive bushels, and spread it evenly over the acre. I then ploughed before the manure had time to dry; then dragged lengthways of the furrows; planted the 9th of May with Dutton corn, the hills three feet apart each way, making 1840 hills with six kernels in a hill. It was attacked by the grub as soon as it made its appearance above ground, at which time I spread twelve bushels of unleached ashes upon it, which checked them a little, but they succeeded in destroying 70 hills, leaving only 4770. These were hoed and thinned to four stalks in each hill, June 6th; then I sowed two bushels of plaster upon the hills, and hoed again July 2nd; put no more earth to the hills than was taken away; went through with the cultivator both ways, four times—June 1st and 6th, July 1st and 12th. On the 14th of September I cut up and shocked the corn, and on the 28th finished husking and housing it.

Upon one square rod, of twenty hills and one fourth of a hill, of the best of the low ground, grew seventy pounds of ears, equal to one hundred and fortyeight bushels per acre. The whole product was one hundred and twenty bushels.

Cost of Cultivation.

One day ploughing,	\$2 00
Harrowing half a day.	1 00
22 loads of manure.	11 00
Planting, 2 days.	1 50
Seed corn,	50
Hoe and cultivator, 2 days,	2 00
Hoeing, 4 days,	3 00
12 bushels ashes and 2 bushels plaster,	1 70
Spreading ashes and plaster,	1 00
Cutting and shocking,	1 50
Husking and housing, 7 days,	5 25
Carting stalks,	75
Threshing, 3 days,	2 30
Interest on land,	3 50
Total cost,	\$37 00

Product.

115 bushels of first rate corn,
Five bushels of second rate,
Stalks, four loads.

WILLIAM INGELL.

Volney, Oswego co., N. Y., Dec. 3, 1839.

I hereby certify, that I am personally acquainted

with the above named William Ingell, and believe him to be a person of truth and veracity, and that his statements may be depended on.

R. D. HUBBARD,

Justice of the Peace.

WOOL.

Few are aware of the importance of this article as an item of our productions, or the amount which it already reaches in the sum total of value. Two years since, the number of sheep was estimated at 12,000,000; it is now not less than 15,000,000.—Allowing the estimate of three pounds per head, the clip of 1839 would be fortyfive million pounds of wool. We have been careful observers of the price of wool, and find it has ranged from 40 to 60 cents per pound, some few lots going above as some have fallen below the prices named. To be sure of being within the amount, we will take the average at 45 cents, and at that rate, the last clip of wool would be worth more than twenty millions of dollars. Yet this is but one item in the productive industry of the north.

At the present prices of sheep and wool, the business of growing them is a profitable one, and may we think with safety be calculated upon as a good one for time to come. Wool of good quality could hardly fail to pay as an article of export to England or France, should present prices abroad be maintained, and the supply for home consumption in this country be exceeded.

To prove that growing wool is a good investment of money, we have only to look at the cost, expenses and returns of a flock. A flock of good ewes, with proper management, will hardly fail of doubling their numbers within the year, and if to the sale of the wool the value of the lambs be added, it will be seen after deducting the expenses of keeping, that a handsome profit remains. But to have good sheep, or good wool, more attention must be paid than is usually given. Sheep that get their living by hook or by crook; that are allowed to gather in their fleeces all the burdock and other weeds that line too many of our roads and fences, and fill our woodlands; that are exposed to all the vicissitudes of our severe and variable climate without shelter, or barely making a living through the winter, cannot be expected to raise many lambs or produce good wool. Wool and silk are to be the great sources of our supply of clothing hereafter, and their importance to the country will be proportioned to their general use.

AMBITION.—Do not aspire to things that are beyond your reach, but be satisfied with the present good which you enjoy. If you are actuated by a laudable ambition, let it be to excel in the profession you have chosen, instead of sinking below in some other. It is a common error of mankind, that they will not be persuaded that every calling or business, has its mixture of good and evil. They see the gilding of the object to which they aspire, but not the canker within.

HOPE.—What a miserable wretch is he who must survive his hopes! Nothing remains when that day comes, but to sit down and weep like Alexander, when he wanted other worlds to conquer.—*Congreve.*

Potatoes were selling at Baltimore a short time since at \$1 per bushel, and scarce at that.

GROWTH OF PLANTS, &c.

Effect of the Change of Season upon Vegetation—Position of the Sap at different seasons—Dry Rot—Method of preventing it—Proper season for Trimming Trees.

A periodical cessation of growth appears to be necessary to the healthy action of most plants, and in this particular we cannot but notice an admirable adaptation of the constitution of plants to those changes of season, which, in some form or another are common to all climates. It is true, that within the tropics, vegetation is not affected by the alternate heat and cold experienced in extra-tropical regions; but yet, very much the same effect is produced upon plants by the change from the rainy to the dry season in those climates, as by that from summer to winter in our own. The effect of the dry season in the one case, and of winter in the other, is not however to produce an entire cessation of all growth; as it appears from experiment that vegetation is at all times more or less active: in the winter it is languid, whilst it is energetic in the spring and summer. The fact that the buds of most plants swell, and that all plants form additions of greater or less extent to their roots during the winter, forbid us to entertain the idea that there is a total cessation of vegetation at that season. But although plants appear to have the power of absorbing fluids by their roots during the winter, they can have but little opportunity of parting with any portion of it again by evaporation, and as a necessary consequence, their tissues become distended and turgid with the sap thus accumulated. This turgidity of the tissues is at its maximum just before the season at which plants put forth their leaves, and is eminently favorable to rapid growth when vegetation resumes its activity. It is a well known fact, that after very long winters, or when a plant has been prevented by artificial means from shooting at its usual season, its branches and leaves are developed with extraordinary rapidity—a circumstance to be ascribed entirely to the accumulation of sap in the tissues.

The diurnal changes from light to darkness appear to be equally important to the well being of plants with the annual changes from summer to winter. If plants were kept incessantly growing in light they would be perpetually decomposing carbonic acid, and would in consequence become so stunted that there could be no such thing as a tree, and this is actually the case in polar regions where the day and night are each of six months' continuance. If on the contrary they grow in constant darkness, their tissues become excessively lengthened and weak, no decomposition of carbonic acid takes place, none of the parts acquire solidity and vigor, and finally they perish. But in ordinary circumstances, plants which in the day become exhausted by the decomposition of carbonic acid, and by the emptying of their tissues by evaporation, repair their forces at night by inhaling oxygen copiously, and so forming a new supply of carbonic acid, and by absorbing moisture from the earth and air without the loss of any portion of it. Such being the case, we must conclude that plants grow chiefly by day, and this is conformable to the few observations which have been made on this subject. Meyer found that the stem of a *Belladonna* lily, and plants of wheat and barley, grew about twice as fast by day as by night; and Mulder states that he has arrived at similar conclusions in watching the development of other plants.

When speaking of seeds and underground stems, the fact was mentioned that the nutritive matter which they contain, and which constitutes their value as articles of food, is, in the economy of vegetable life, intended for the sustenance of the young plants to which they give origin, during the early stages of the growth of those plants, and before they have become sufficiently developed to acquire nourishment for themselves. The heart-wood of trees appears to stand in a somewhat similar relation to the young buds of a tree, serving during the winter as a depository for the turgid sap which the plant accumulated, and yielding it up again so soon as the flow of the sap has fully commenced in the spring. The sap which accumulates in the sugar maple (*Acer saccharinis*) during the winter, contains a large portion of sugar in its composition; in the spring, as the watery sap imbibed by the roots ascends the stem, it gradually dissolves this sugar out from the heart-wood, and carries it up for the nourishment of the then swelling buds; of course, the higher the sap ascends the stem, the more of this sugar will it have dissolved; and this is the reason why it is found necessary, in tapping that tree for the purpose of obtaining sugar from its sap, that the openings should be made high up the stem, and not near the root; and further, that they should be made to enter the heart-wood, and not to pass through the bark alone. I know that these facts respecting the sugar maple have been adduced in support of the idea that there is no such thing as a downward flow of the sap, and that its elaboration instead of taking place in the leaves, takes place gradually during its ascent; but the downward flow of the sap is established by so many incontrovertible facts, that even if we could not give any explanation of this matter, we could by no means admit it as establishing the theory just adverted to.

A knowledge of the position of the sap at different seasons of the year, is of great importance to those engaged in cutting timber; and as all farmers are obliged to engage in this business more or less frequently, they will find this a matter well worthy of their attention. It is now, I believe, universally admitted that that disease so fatal to timber, the *dry rot*, arises from the presence of the sap, more especially of the thick turgid sap, which cannot be well removed by seasoning. If then such sap fills the tissues of the heart-wood during the winter, whilst they are free from it in the summer, we will at once see the bad policy of cutting timber in the winter, as is the common practice; and also a reason why the timber of the ancient Romans (who it is believed, usually cut their timber in the summer,) lasted so much longer than our timber at the present day. I do not know that I can place this subject fully before my readers in any better way, than by transcribing a part of a communication which appeared in the 34th vol. of the *American Journal*, written by Phineas Rainey, a ship-builder of Connecticut.

"It was the general custom here, to cut timber for vessels in the winter, notwithstanding they went into decay and wanted repairing in about seven years, or from that to eight, whilst a few only lasted twelve years. I ascribed this variation in their durability to the fact that the cutting of timber was often commenced in October, and then continued through the intermediate months to March. I therefore concluded that the right season was in December, when I supposed that the sap was certainly in the roots, and if cut at this season, I believed that

it would leave the deadly poison in the stump, whilst the body and branches would be entirely free from its influence. I determined to carry this opinion into practice the first opportunity that occurred.

"In 1810 I was concerned in the building of a small freighting ship, of which I was the sole conductor, from her keel until she was completed and ready for sea. According to my previous determination, I commenced the cutting of the timbers for her in the early part of December, and continuing it into the first week in January. By so doing, I expected to produce the very best ship for durability on the Connecticut river, where there were then numerous vessels building. The timber selected was white oak and white chestnut.

The vessel advanced, and in April it was found that three of the quarter top timbers were wanting and as very crooked pieces were required for these I was obliged to go into the woods and have them cut. Sometime in May, it was found that the steel designed for plank-sheers (this was very large and intended to make the whole that was wanted,) would not answer the purpose, except that it was barely sufficient to go around the bows, the other part being badly rent, and of course rejected. I therefore went into the woods a second time, when the leave were full grown and the bark would peel, and had two thrifty white oaks cut for the after pieces.—These timbers were put in immediately, and saved the plank-sheers, without any seasoning what ever, and the room between the timbers above the air-streak, was filled with salt, which was supposed to be a preventive against the dry rot. The workmanship was of the first order.

The vessel was launched and completed in Jul 1811. That autumn she went to sea, and after the declaration of war in 1812, she came to Middletown and was laid up until the peace of 1815. In the spring when she was to be fitted out again, it was found that she must be repaired in her hull; and on opening her, it was perceived that the dry rot had made such destruction among her timbers, that it was necessary to build her anew from her mid-le-wale up. But the three quarter timbers spoken of, which had been cut green, were sound, and appeared new, although their neighbors on each side of them were destroyed by the disease; and is a remarkable fact, that the spikes when pulled out of them, were bright, and appeared new; but those parts of them which come in contact with the outside planks, (which were made from timber cut in December,) were badly oxidated, so much so that they were reduced in size about one quarter. The forward plank-sheers which it will be remembered were cut in December, were destroyed by the disease; but the after pieces were sound as dry, and on the under side appeared like new timber seasoned in the shade; and what is remarkable as to them is, that although some of the timbers on which they rested were so decayed that they might be picked to pieces, yet there was not the least appearance of it on them, which shows that although surrounded by corruption, they were themselves at least up to that period incorruptible. Thus it can be seen, as respects this vessel, that not only the season of the year, which in the popular opinion is the best to cut timber in for the purpose of making it last well, was strictly adhered to but also the precautionary measure of applying salt which is even at this day thought to retard the progress of the disease.

"Although at that time it was not thought nece

ry to repair this ship below the middle-wale, yet have every reason to believe that the poison had begun its work in her timber from light-water mark to her top-side: for, in 1816 or 1817, in a perfect limb, she sank at sea, a poor, miserable decayed hull—a melancholy comment on the folly of cutting timber for vessels in the winter months. By enquiring since, I have always found that of those vessels which last the longest, the timber of which they were constructed was cut the farthest from December. When I have known the period at which certain trees have been cut, and also their quality, I have afterwards year after year examined their stumps, and watched their decay; and have invariably found that in those of them which were cut in the winter, the disease first made its appearance in the heart-wood, and continued its progress until that was destroyed, and up to that period the albumen was comparatively sound; whilst those which were cut in the summer, the disease first made its appearance in the albumen, which a few years entirely disappeared, whilst the heart-wood remained sound.

“There are numerous facts in the most common transactions of life that will sustain me in my position. I believe that the general practice throughout the northern and middle States is, to peel such trees as are to be manufactured into ship-plank; saving the bark, this probably makes the business more profitable than it would otherwise be. It is invariably the case that by the time the plank becomes thoroughly seasoned, the albumen becomes so much injured by the dry rot as to be unfit to be used; and for my own part I never saw a piece of timber of this sort, where the heart-wood was protected at all, unless the tree had evidently contracted the disease before its death. The season of peeling is from the third week in May to the end of June. Farmers cut their rails in the summer, when the bark will peel, and they last from a few months to a hundred years. They account for this in the following way: if they cut them in the winter, the bark will stick fast to the rails, and after a little while the water gets under it and causes them to decay sooner. On the contrary, they cut their rails in the winter; probably this is done for the convenience of cutting holes in them at that season; and although their rails last so long, yet their decay begins to decay in seven or eight years, according to the soil in which they are placed. When a necessity they are obliged to cut a few posts in the summer, (with the expectation, however, that they will soon decay) if they last thirty or forty years (and there are instances of this kind,) they look off as a very remarkable circumstance, but are inquired into the natural cause, nor alter their opinion. There are other instances of the extraordinary longevity of timber: wooden abutments to bridges, pumps, piles, foundations of weirs, cofferdams, &c., a full notice of which would fill a volume—all going to show that there is a season in which if timber be cut, it will last for many years and the average time for which it now lasts; and that there is a season in which if it be cut, it will not last over eight or ten years, notwithstanding any artificial process through which it may be made to pass. In my opinion, June is the best season in which to cut timber, in order to make it last as long as possible, though I do not suppose that it would make any great difference if it were cut in either of the other winter months.

At the period at which I was strenuously advo-

cating the doctrine of cutting timber in the winter, I had a small apple tree which had been engrafted with a choice fruit, and had been growing perhaps seven or eight years. There was one limb on it which I did not like, because it was growing in a wrong direction. I took it off in December, because I believed the sap to be then in the roots, and therefore at this season there would be none of it wasted or taken away with the limb, and of course the branches left would receive a greater portion of nourishment in the spring. Sometime afterward, I examined the tree, and found that the part or stump of the limb which remained within the surface of the body, was affected with the dry rot in its purest type. I removed this with my knife, and found that the disease had made its attack on the body of the tree itself. The tree, after the limb was taken off, became sickly, and its fruit after it began to bear was imper ect.

“I would here observe, that it is the common practice when people cut the timber of a house-frame, to do it in the winter, because, as they think, it will be more durable; but they will not trim their trees at that season, because they have learned from experience that if they do, the trees will contract the dry rot; therefore they do it in the spring. But Dr Ives, of New Haven, goes even further; he trims his trees in June, and thinks they do better at that season of the year, because the wounds heal quicker. This is right, for as the immediate cause of the disease is not contained in the heart-wood at that season, therefore the remaining stump being almost all heart-wood, can never be attacked by the disease, and the wound will heal quicker; but if the trimming be done in December, the cause of the disease is contained in the stumps at that season and as they cannot be removed, the consequence is, that the disease soon attacks and destroys them, and then the wound will never heal. Although trees thus situated may, by their abundant foliage, their extended branches and their smooth bodies, appear to be in perfect health, (which is sometimes the case,) yet they are doomed trees; for the canker having entered into their organization, is preying upon their very vitals, and will sooner or later, prostrate them in the dust.”

In the communication from which the preceding statements have been taken, there are many other facts given, all going to establish the same point, viz., that timber should be cut and trees should be trimmed in the summer, and not in the winter, as is the common practice. I should remark, however, that these statements concern more especially such timber as the oak, chestnut, &c., and not those trees whose heart-wood is filled with resinous matter, such as the different species of pine; in the case of these last mentioned trees, I do not suppose that it will make much difference at what season they be cut. Perhaps it may be objected to cutting timber in the summer, that a farmer is generally so busy at that season, that he cannot spare the time necessary from his other occupations. But let it be recollected that it is not necessary that the timber should be fully prepared for its intended use at that season, but only cut down, or perhaps even girdling would do, if it be made sufficiently deep to kill the tree, and the work may then be left to be finished at a time of greater leisure. Should a farmer be obliged to hire this done, the expense incurred would be far more than repaid him, by the additional durability of the timber.—*Farmers' Register.*

CHOICE OF EMPLOYMENT.

At the present period of general derangement in almost every department of business, it is natural for all inquiring minds to cast their eyes around them in search of some pursuit calculated to yield them a support, or to advance their pecuniary resources. And where, let me ask, does the mind meet a certain resource except from the productions of the soil? and where else can one look for stability as to the safety of his investments, and to an ample return for his labors? What other pursuit can offer to him a sure guarantee of a comfortable support for his family, and permanent provision for his children? In commercial pursuits all is chance and uncertainty, and he who can boast of being on the ascendant to-day can only claim to occupy the reverse position on the morrow. The history of whole streets in our mercantile cities is but a record of the rise and the downfall of their occupants. It is a melancholy reflection, that such are the uncertainties attendant on commerce, and on mercantile affairs generally, that every six or seven years witness a complete revolution in the mercantile class of the community. And yet such has been the folly and absence of proper discrimination among parents generally, that apparently it has been their most anxious desire to devote their sons to mercantile pursuits, and to risk their prosperity on chances as fluctuating and more uncertain than the turn of the die. It is to this gross misdirection of the mind that many branches of agriculture have to this day been totally neglected, although offering the most bountiful returns to those who would engage in them. Providence planted the vine alone in Persia, Syria, and North America. To France and Italy he tendered no such tribute. And yet we see France, whose climate was so uncongenial to the vine at its first introduction, that it could barely survive on its most southern shores, now become enriched beyond every other nation by the immense accumulation of wealth which, for ages, her vintage has poured into her bosom. We see that country becoming affluent and powerful, not from the natural productions of her own soil, but from those which she has borrowed from more favored climes. Look at her olive groves, and the whole race of oleaginous plants from which she derives the immense quantity of her choicest oils, sufficient, almost, for the consumption of the whole earth. Look at her groves of almonds, figs, prunes, and almost every other fruit calculated to give support to her citizens and amplitude to her commerce. And lastly, look at her immense and increasing plantations for the silk culture, rivaling in profit all her other pursuits. Not one of these invaluable productions is the gift of nature, but all exotics, transplanted to her soil. For ourselves we may claim both the vine and the mulberry as pre-eminently our own, and planted on our soil by the God of nature. And thus favored, shall Americans succumb and yield precedence to nations possessing few natural advantages? Shall we shrink from the development of these resources which Providence himself has marked out as peculiarly calculated to enrich our country and extend our sphere of comfort and happiness? We trust not. We trust that we shall not have, for the future, any recreants among us, who doubt the triumph of American skill, enterprise, and industry, where any other nation dare claim success. It is such men who retard the national advancement, and are a clog to its prosperity. They are worse than drones, for they impede the labors of the industrious.—*Silk Journal.*

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, FEBRUARY 5, 1840.

☐ We promised this week a report of Dr C. T. Jackson's remarks at the Second Agricultural Meeting; but for reasons which we trust will be satisfactory to our readers, we must beg for absolution. We have, with as much care as we could exercise, prepared full reports of Dr Jackson's remarks at the second and the third agricultural meetings, and of the remarks of Judge Hayes at the third agricultural meeting. But owing to the indispensable necessity of a portion of the paper going to press before these reports could possibly be prepared in a manner just and satisfactory to the speakers, to the public, and to ourselves, we could not insert either of them this week, without division or mutilation. To this, on various accounts, we are reluctant. They will, however, go on to the first pages of the next week's Farmer, and will, we have no doubt, be read with very great pleasure.

H. C.

THIRD AGRICULTURAL MEETING.

The Third Agricultural Meeting was held at the Representatives' Hall on Thursday, 30th January. In the absence of Mr Dodge, Mr Fowler, representative from Danvers, was appointed secretary of the meeting; Hon. D. P. King in the chair.

It was voted that gentlemen having questions relative to the subject of the evening's discussion, to which they desired an answer, should present them in writing to the secretary at the opening of the meeting. They should then be read, that the speakers might reply to them, if they found it convenient. It was understood, however, that this was by no means to preclude the offering of questions orally, which might grow out of the occasion, so that there should be no restraint upon free conversation and discussion.

It was also resolved that gentlemen from other States, who might happen to be present on the occasion, should be considered as members of the meeting, and invited to take part in the discussion.

The subject of the evening's discussion was Soils and Manures, continued from the last meeting; and the assembly was addressed at large by Dr C. T. Jackson, who recapitulated his former remarks and enlarged upon topics then briefly touched; and by Judge Hayes, of South Berwick, Me., a very intelligent and practical farmer, who happened to be present; and who was kind enough to respond to the call of the chair, and gratified and instructed the meeting by an account of his farming, and the improvements which he had effected. H. C.

A CARD.

We have received from some unknown friend at Halifax, a small parcel of Chevalier wheat, we suppose, grown there. He will please accept our thanks and be kind enough to add to the obligation by letting us know who he is and how we may serve him. We should be very glad likewise to know the history of this wheat. We hardly think we ever saw any product so fine; certainly we have never seen it surpassed. It is a winter wheat, and we shall seek to place it in hands which will give it a fair trial. It has been said that winter wheat frozen in water and so kept until spring, may be planted early in the spring, and will come to maturity the ensuing fall. We have no personal or certain knowledge of this process, but if any friend is disposed to take a portion of this sample and make this kind of experiment with it, it shall be at his service.

We are indebted to Mr Goddard, of Brookline, for a fine specimen of early corn, from seed which we gave him; and to Mr H. C. Merriam, of Tewksbury, for a fair sample of the Brown Corn, for which they will please accept our thanks.

We have likewise received from Dr Deane, of Greenfield, a splendid sample of raw silk, the product of his own industry and skill in raising and reeling. He has been honored by the American Institute for some of the same product with a silver medal. We only wish we had a gold one to give him, for he deserves it.

We are indebted likewise, to the Northampton Silk Company and to Mr Haskell, of Harvard, Mass., for some excellent specimens of sewing silk, which show that this beautiful cultivation and manufacture needs only to be undertaken to go on to perfection.

To David L. Child, Esq., likewise, we are indebted for some fine specimens of beet sugar, manufactured by him at Northampton, in a crude and refined state. They are equal to any sugars of the same description, and entirely free from the earthy, or as some would have it, the beet taste, which has been objected to in this product.

These productions will be exhibited to the farmers and others interested, at the agricultural meetings; and they have only to be seen to be admired.

HENRY COLMAN,
Commissioner of Agricultural Survey.

February 5, 1840.

THE FOURTH AGRICULTURAL MEETING

Will be held at the Representatives' Hall on Thursday evening next at 7 o'clock. The subject proposed for discussion, and for that purpose committed to Mr William Clark, of Northampton and Mr Allen Putnam, of Danvers, both of the House, was Indian Corn; but as it was agreed, in case of the acceptance of the invitation given to Hon. Isaac Hill, of Concord, N. H., to address the meeting on that evening, (an answer to which had not then been received,) the subject for discussion will be the Improvement of the Agriculture of New England—on which subject, we have great pleasure in saying an address may be expected from this gentleman, the editor of that excellent journal, the Farmer's Monthly Visitor, and eminent for his agricultural zeal and intelligence.

We cannot doubt that there will be a full attendance on this occasion, and that those farmers of the Legislature who have failed to attend the two last meetings on account of the wet walking, having, we presume, brought nothing but pumps with them, will at once send home for their well-soled and well-grassed cow-hide boots. We shall speak to the Sergeant-at-Arms to admit them, though having an extraordinary organ of order, he might have some little fears for his carpet.

We beg leave, likewise, to remind some of our friends, certainly, however, none of the Committee, that seven o'clock means precisely one hour after the Old South strikes one, two, three, four, five, six! and not that it is seven until eight; a principle absolutely immoral in itself, and which, if carried out into the various departments of life, completely tangles the web and throws every thing into disorder.

The committing of a subject to a committee, as mentioned above, is by no means intended to prevent or preclude discussion; but merely that the subject proposed might be particularly considered by the gentlemen to whom it was intrusted, so that when the meeting should be opened the discussion might proceed without delay, and with one at the team and one at the handles of the plough, there might be no difficulty in striking out the land, and going the first bout. H. C.

THE SLAYING OF THE DRAGON.

The Legislature have been occupied the last week in attempting to destroy a terrible dragon, called the License Law, which has been roaming over the State the last year, threatening to eat up the liberties of the people. The captain general of our armies, with the courage of a veteran of Waterloo, marched up boldly to the onset, and gave him a fatal blow under his thickest scales. This was followed by a general rush of the bravest of both political parties to be in at the death. By the time the compositors had dropped the types from his fingers he will probably have entered his last expiration. A few centuries hence no doubt, the learned geologists of that period on exhuming his remains, will class him as a Megatherium or a Saurian, found in remote ancient formations; and some new Cuvier will arise to determine his genus and habits; and then there will be learned speculation among the philosophers and the gaping crowds, of how many living beings he must have devoured and how terribly he must have alarmed the poor women and children. As he is the only individual of the race that ever has, or probably ever will exist, there will be extreme difficulty in determining his place, and he will be regarded as constituting an entirely distinct class of the Carnivora. H. C.

CANKER WORM.—The Boston Courier recommends a *bi* fit subject for discussion at the agricultural meetings in Boston, the best mode of destroying the grub or egg of the canker worm in the ground before it ascends the tree and also suggests to the legislature the expediency of offering a liberal premium for the discovery of a remedy against its ravages. It is not probable that in the present state of the treasury, the latter suggestion will be adopted. Its object, however, would be accomplished, if some of the funds of our agricultural societies were devoted to this purpose. No more useful appropriation of a portion of their funds can be made.—Hortester Ægis.

We saw the notice in the Boston Courier referred to above, and were not regardless of the suggestion therein made to the Commissioner of Agricultural Survey. The natural history of the canker worm and its habits were fully investigated by Professor Wm. Dandridge Peck, in 1827, and his Essay, presented to the Massachusetts Agricultural Society at that time received a premium of fifty dollars. It was published in their memoirs, and we design soon to lay this and the Essay by the same gentleman, on the natural history of the slug worm before the readers of the New England Farmer. The Massachusetts Society have almost constantly from that time to this, offered a liberal premium for the discovery of any effectual mode to prevent the ravages of the canker worm; and we will answer for the trustees of that Society who have rendered immense services to the cause of an improved agriculture, that they will be ready at any time to reward with liberality such a discovery, whether it be or be not specified in their list of premiums.

We are yet known of but one effectual remedy against the canker worm, that is the encouragement of the birds. They are the best friends of the farmer and the gardener. In our code of penal justice, killing a small bird should be placed next to killing a child. We were assured the last summer, that at the beautifully cultivated district of Cambridge called 'Flob,' (have the name altered, we pray,) abounding in fruit, they were entirely free from canker worms, while in Old Cambridge the orchards suffered severely. The great security which they found was in the encouragement and preservation of the birds. A gunner in West Cambridge would be in as much danger as an abolitionist in South Carolina. H. C.

Massachusetts Horticultural Society.
EXHIBITION OF FRUITS.

Saturday, Feb. 1, 1840.

By S. Downer, Esq.; Catilae and Iron Pears—good specimens. Fine samples of the old Nonpareil, K. L. Greeneing, Newton Pippin and Royal or Old Pearmain Apples; and very superior specimens of the Golden Russet and Wales apples—the two last very beautiful, and richly deserved attention among cultivators of fine apples.

E. M. Richards, Esq. exhibited fine specimens of Pomme d'Api (Lady Apple) and L. Echassari and Gloux Moreau Pears. For the Committee,
J. L. L. F. WARREN.

BRIGHTON MARKET.—MONDAY, Feb. 3, 1840.
 Reported for the New England Farmer.
Market 245 Beef Cattle, 1190 Sheep, and 70 Pigs.—*Beef Cattle*.—A small advance was effected a yoke or two purchased on Saturday may have had something more than our highest quotations. Quality, \$6 75. Second quality, \$6 00 a \$6 50 quality, \$5 00 a \$5 75.
Feeding Cattle.—Mess \$5 50; No. 1 \$5 00. *Wool and Catres*.—\$23, \$33, \$37 and \$40.
Wool.—The prices obtained last week were hardly reduced. Lots at \$2 25, \$3 00, \$3 25, \$3 75 and \$4 00.

Wool.—A part of those at market were from the neighborhood. About 25 only were peddled from 4 1-2 to 5 1-2.

THERMOMETRICAL.

Reported for the New England Farmer.

Temperature of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded place, during the week ending February 2.

AGRICULTURAL BOOKS.
 J. BRECK & CO. offer for sale a great variety of agricultural books, among which are the following:
 "Encyclopedia of Gardening."
 "of Plants."
 "of Agriculture."
 "Suburban Gardener."
 "s Horticultural Observations."
 "Practical Agriculture, by David Low."
 "Practical Agricultural Chemistry."
 "on the Cultivation of the Carnation and other Flowers."
 "Florist Cultivator."
 "Gardeners' Assistant."
 "Gardener's Assistant."
 "Complete Farmer."
 "Orchardist."
 "Gardener's First Book of Fruits."
 "Fruit Garden Companion."
 "Flower Garden Companion."
 "on Sugar Beet, by David Lee Child."
 "on the Sugar Cane."
 "ography of the Genus Camellia."
 "Silk Manual."
 "do."
 "s Silk Growers Guide."
 "on the Mulberry Tree and Silk Worm."
 "s Horticultural Observations."
 "s Encyclopedia of Botany—The Young Florist."
 "Treatise on Bees."
 "ry 5."

SCIONS OF FRUIT TREES FOR SALE.
 The collection of fruits cultivated at the Pomological Garden consists of more than 1400 varieties of the Apple, Pear, Plum, Cherry and Peach. Scions of all those which have been proved are offered to nurserymen and others. Gentlemen wishing to send collections of American fruits to their friends in Europe can be furnished with most of those of first rate quality. They are warranted true to their names, and are in all cases cut from fruit bearing trees.
 Salem, January 23, 1840. ROBERT MANNING.

AMERICAN SWINE BREEDER.
 Just published and for sale by JOSEPH BRECK & CO. the American Swine Breeder; a Practical Treatise on the Selection, Rearing, and Fattening of Swine, by Henry W. Ellisworth: price 75 cents. For sale at 51 and 52 North Market Street, January 15.

FOR SALE.
 An excellent Farm, pleasantly situated about 20 miles from the city, containing about 100 acres. For full description, particulars, &c. inquire at this office.
 Also, a situation wanted by a man with a small family to carry on a farm.
 January 30. 4w

POSITION WANTED AS GARDENER.
 A man, who has no incumbrance but his wife—practical experience is known to the amateurs of the art. His commands addressed to Joseph Breck & Co. will be promptly attended to.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO. at the New England Agricultural Warehouse and Seed Store, Nos. 51 and 52 North Market Street, have for sale, Green's Patent Straw, Hay and Stalk Cutter, operating on a mechanical principle not before applied to any implement for this purpose. The most prominent effects of this application, and some of the consequent peculiarities of the machine are:

1. So great a reduction of the quantum of power requisite to use it, that the strength of a half grown boy is sufficient to work it very efficiently.
2. With even this moderate power, it easily cuts two bushels a minute, which is full twice as fast as has been claimed by any other machine even when worked by horse or steam power.
3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.
4. The machine is simple in its construction, made and put together very strongly. It is therefore not so liable as the complicated machines in general use to get out of order.

VEGETABLE CUTTER.

Willie's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and esculent roots for fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public; they are aware that it has been long wanted and they now offer a machine that cannot fail to give satisfaction upon a fair trial. It will cut with ease from one to two bushels per minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at the Agricultural Warehouse, 51 and 52 North Market Street, December 15. JOSEPH BRECK & CO.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone, and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and no charge for casks or carting.

Also, ground Oyster Shells
 Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.
 NAHUM WARD.

MISCELLANEOUS.

JUDICIAL ANECDOTE.

The courts of Vermont have been celebrated for many years for the wit and amusing peculiarities of several of their justices. Anecdotes are rife respecting them, from the rough and coarse humor of Harrington, to the more polished scintillations of his successors of modern times. Nothing can be more racy than the following, which we are confident is new to the majority of our readers.

Judge ——— had effected a settlement of accounts with one of his neighbors, a very simoniacous man, and it was found impossible to make correct change within *three cents*, which the judge said he would hand to the other at any subsequent period. Some days after, while the judge was upon the bench, and in the midst of a cause, the avaricious neighbor, whose brains could not rest while the three cents were absent from his pocket, appeared in the court room, and with slight ceremony, beckoned to his debtor to grant him an interview. The judge, who was so unfortunate as to stutter somewhat, appreciated instantly the purpose of the applicant, and arrested the progress of the case, with "st-stop, a f-f-f-moments, unt-until I speak t-t-t to my neighbor P——." He thereupon descended from the bench, and accompanied neighbor P. to a private room, and, as he expected, received a demand for the delinquent three cents. He paid it, obtained a receipt, and returned to the court room, convulsing every one present with laughter, by the following remark: "th-they s-say, th-that at t-t-the m-m-m-moment any one d-d-dies, another is b-b-born, and the s-soul of t-t-th-the one that d-d-dies goes into the b-b-body of t-t-th-the one th-that's born. N-now, w-when neighbor P. w-was b-b-born, a-n-nobody died."—*Ladies' Companion.*

CAPTURE OF A BEAR.

For the last twelve years, there has been residing within forty minutes ride of this city, in the town of Brewer, near the "Big Pond," so called, a mischievous animal called a bear, of the hog species, with a brown proboscis, and short, but strongly sinewed legs; during which time, he has fattened upon the corn, cattle and sheep of the farmers who lived in his vicinity. During the past year alone, he has destroyed upwards of one hundred dollars worth of stock, always taking care to secure his retreat when pursued, till within a few days, when he was accidentally discovered by some men who were employed in logging near the spot where he had taken quarters for the winter. Observing his tracks in the snow, they traced him to the mouth of his den, which was in the cavity of a ledge; when they commenced removing the brush he had carefully drawn into its mouth.

In a moment old Bruin began to snuff and growl, and made an attempt to take leg bail, but was saluted with a blow from an endgel, cut for the purpose, and fell back into his domicile, where he quivered for a few moments, but suddenly regained his strength, and made good his escape for the time being. The next day he was hotly pursued by some half dozen of those on whose stock he had preyed, and the chase was continued for some five or six days, when Mr Blood came to this city and informed some of our sportsmen (we have some old ones too,) who, accompanied by their hounds, immediately joined in the chase. and fif-

teen days from the time the bear was first started from his den by the loggers, (during the whole of which time he was hotly pursued by men and dogs, having been kept on the traup the whole time, only excepting nights) he was captured and brought into this city by Capt. Nye, and Mr Leonard Dow.

On examining him, thirteen balls were found to have pierced him: the last shots, however, were those which gave him his *quittus*—one of which took effect a little above his fore shoulders, and the other near his spine. During the whole fifteen days, Mr Blood, who is a farmer, kept open house, keeping all of those free of expense who were disposed to join in the chase, being determined to have the bear before he gave up. He weighed when killed, three hundred and twenty-four pounds. The old hunters say he must have "run off" one hundred pounds during the chase—but still he is a lusty fellow, and you Bostonians may prepare your mouths for a taste of his flesh, as I understand it is the intention of Mr Dow to ship him at Frankfort for your city. He has been on exhibition in this city for the last two days, at 12 1/2 cents a sight.—*Bangor Democrat, Jan. 12.*

GREAT WALL OF CHINA.

Even when united under one emperor, China trembled at the Tartars of the desert. About two centuries before the birth of Christ, She-hwang-te (the book-burner) constructed the great wall of China, to prevent their incursions. The wall, which has always been considered one of the world's wonders, is 1500 miles in length, of great height and thickness, furnished with fortresses and towers innumerable, and is carried with singular skill over mountains and rivers, as well as across the plains and valleys. Lord Macartney exclaimed on seeing it that it was certainly the most stupendous work of human hands, and he rationally concluded that at the remote period of its building, China must have been a very powerful and civilized empire. Dr Johnson was accustomed to say of it, that it would be an honor to any man to say that his grandfather had seen the great wall of China. Mr Barrow who saw it with Macartney, went into some amusing calculations as to the quantity of the materials it contains. According to his account, all the materials of all the dwelling houses of England and Scotland, supposing them at that period (at the end of the last century) to amount to 1,800,000, and to average 2,000 cubic feet of brick work or masonry, would be barely equivalent to the bulk of the wall, without taking in its fortresses or towers, which he calculated contained as much masonry and brick work as London did at that time. Stupendous as was the work, it failed in its object.

A Swedish peasant spoke contemptuously of the King, saying—"I don't care a fig for Bernadotte." The peasant was arrested, and under an ancient law of the kingdom, condemned to death. The King immediately pardoned the peasant, and ordered the law to be repealed. "But," said the King to the Judge, "I do not like to be insulted, and therefore I cannot let this man pass off without some punishment; you will therefore please to go to his house and say to him in my name—'Since you don't care a fig for Bernadotte, Bernadotte don't care a fig for you.'"

The number of lives lost by shipwreck of American vessels last year is stated at 537.

FAITHFULNESS OF A DOG.

In the unhappy and too memorable winter of 1790, when the corn, the vine, and the olive, were destroyed by severe cold in France, the wolves made dreadful ravages in the fields, and rushed with voracity even upon man. One of these ravenous beasts, after having broken the window, entered a cottage in the forest of Orte, near Angoulême. Two children, one six, the other eight years of age, were reposing on the bed, in the absence of their mother, who had gone in search of wood to kindle a fire. Meeting with no resistance, the wolf leaped upon the bed, and sought to destroy his delicate prey. Seized with a sudden fright, the two little boys crept quickly under the covering, and held it closely without drawing a breath. So near was the flesh which had enticed him, that not being able to attain it instantly, the murderous animal became more furious, and began to destroy the covering with his teeth. Trifling as was this obstacle, it nevertheless preserved the lives of these innocent children. A large and faithful dog, who had followed their mother, returned in time to deliver them; he had scented the track of the wolf at more than a hundred yards from the house, whither the mother was returning slowly, loaded with faggots; he ran with the quickness of the stag—he entered like a lion, and falling upon the animal, who had endeavored to secrete himself in an obscure corner, he seized the base wrangled by the throat, and dragging him to the door, stretched him instantly. The alarm of the mother on her return was indescribable. She beheld the wolf stretched upon the earth, the dog covered with blood, her bed in confusion, her children gone. Observing the distress of his mistress, the dog ran towards her with the most energetic solicitude, then returning to the bed he thrust his head repeatedly under the covering, and by the most expressive signs endeavored to intimate to her that she would find there that which she held most dear. The mother approached, and extending her trembling hand, discovered that her children were there, although deprived of motion; she hastened to restore them—there was yet time; a moment's delay would have rendered the attempt useless. When they had recovered their senses, they plainly recounted the danger to which they had been exposed, the manner in which the wolf had entered, and their wonderful preservation. The faithful animal, pleased in having saved the lives of these little innocents, by his eager caresses gave ample testimony that his joy was equal to that of his mistress.

A MAN WANTED.

To do the work on a small place, a few miles from the city. He must understand the cultivation of vegetables, fruits, &c., and the care of horse, cows, &c. A single man, from 20 to 30 years of age, of steady and industrious habits, may inquire at this office.

BOSTON, WEDNESDAY EVENING, FEBRUARY 12, 1840.

[NO. 33-

N. E. FARMER.

We give below a sketch of the remarks of Dr. C. Jackson, at the Second and Third Agricultural Meetings, on *Soils and Manures*. Our notes, as we have before said, in such cases are very imperfect, our aim is simply to give the ideas and statements of the gentlemen whom we report, not attempting to retain their language. Under such circumstances, it is a matter of no small labor and duty to write them out in full; and we must in the indulgence of our readers for the dress in which these remarks appear, and for which their errors are not responsible. We have deemed it too valuable and interesting to be lost.

It must not be forgotten, however, at the same time, that, if we have not misrepresented them, (as we trust we have not,) they, and not we, are responsible for the statements made and the opinions given. Because we give these opinions it is not therefore to be inferred that we adopt them; but we deem it courteous to interrupt the discourse by interpolation of our queries, distrusts, or objections. From some of the notions of our friend Jackson, we dissent—but that by no means implies that he is in error; and we give them for the benefit of our readers with all the claims to respect and confidence, to which his intelligence, distinguished learning, his indomitable spirit of inquiry, and his persevering industry entitle them. His opinions and evidence are the great objects of all sound philosophy; and all that we want for these are fair and an open field.

H. C.

SPEECH OF DR. C. T. JACKSON,
Medical Surveyor of Maine, New Hampshire and Rhode Island, at the Second and Third Agricultural Meetings.

Dr. Jackson began by expressing the pleasure he felt in these meetings for mutual information and improvement; and he argued the most beneficial results to flow from the active spirit of inquiry which was so generally awakened.

Agriculture is yet to derive immense advantages from scientific cultivation. The first element in agriculture is the soils, which constitute the seat of operations. The soils which the earth presents, and which in different localities are found differently constituted, although the same elements enter, to a certain extent, into the constitution of all of them, are among the most important objects of inquiry and examination to the diligent farmer.

Soils are, properly speaking, only the *debris* or the substance of decomposed rocks, intermixed in various degrees with organic matter in a state of solution and diffusion. The breaking down and comminution of the rocks, so as to form the particles of the earth, have been the progressive results of the influence of air, moisture and exerted through many ages which have passed, still in constant and active operation. That the earths were derived from the disintegration of

rocks, he deemed conclusively established by the fact, that by the chemical and indeed microscopic examination of soils, they are found to consist of the same elements which enter into the formation of the rocks. In soils derived from granite were found quartz, felspar, and mica; and the decomposition of slate rocks produces clay. The presence of limestones and porphyry serves in each case to produce a peculiar soil.

All the various mineral bases have an influence upon the character of a soil. Some of these minerals undergo a decomposition and enter directly into plants: silex, alumine, magnesia, all enter into plants; and silex, as is well known, forms the coat or skeleton of all grainaceous plants, or otherwise of plants belonging to the family of the grasses. These elements have much to do with the fertility of a soil.

The enriching mineral substance found in New Jersey, alluded to in a former discussion, is what is called a green sand, composed of silex, potash, and iron. It yields potash, and thus neutralizes any acid substances which may exist in the soils, to which it is applied.

Every observing traveller in passing through different countries, perceives that the soils of different countries possess properties peculiar to themselves. Thus limestone soils seem most congenial to the production of wheat; and granitic soils to that of grass. Each rock may be traced by its peculiar vegetation. The soils on the trap-rock formation in this State, are distinctly marked.

A great part of the State is of what is called the diluvial formation. In this case there is an evident removal of the earth's surface or soils by some violent convulsion in a sort of wave, from the north to the south. The proofs of this deluge in its advances south may be distinctly traced. Thus in a diluvial formation the soils will be found to be composed of the same elements as the rocks some miles distant to the northward of that place; and may be very different from the soil, which might be said to belong to the place, where they are found. As evidence of this movement south, the rocks in the vicinity of Providence are evidently formed from the disintegration of rocks of the greywacke formation some distance to the northward. The greywacke rocks are those composed of other rocks of various descriptions collected together in a miscellaneous combination, and cemented by a kind of argillaceous paste. In Maine there are abundant proofs that the whole soil of the country has, in many places, been removed southwardly. In Thomaston the soil is evidently of diluvial formation. Portland rests upon a formation of mica and talcose slate; but the soil is granitic and evidently transported from the vicinity of Brunswick.

The diluvial soils were transported by some extraordinary change in the earth's surface, produced, it may be, by a deluge or some similar catastrophe. Alluvial soils are formed from the washing of high places into those which are lower, by rains or freshets, and take place by a gradual deposit of earths or sands from water thus rendered turbid. The di-

luvial soils have a higher antiquity than the alluvial. The fertility of alluvial soils is owing, in a considerable measure to the fine comminution of the particles of which they are composed. This allows the roots of plants to spread themselves freely. There is much vegetable matter mixed up with them, though these soils are not remarkable for its abundance. Upon an examination of the alluvial soils of the Mississippi, the Ganges, and the Nile, they are found nearly to resemble each other, with the vegetable matter contained in them in a finely divided state.

The mixed elements of soils have a powerful action upon each other, and upon the plants which grow in them. Their earthy parts have an electro-motive power, which operates not only by the roots but by the leaves. A fertile soil consists of elements in a positive and a negative electric state, fairly balancing each other. If the soil is acid, it is barren; if alkaline, barren. The acid is in a negative, the alkaline in a positive electric state. Vegetable manures become acid or negative; animal manures positive or alkaline; they must be combined in order to produce the best results. When peats alone are used for manuring soils, the results are not always favorable. Farmers pronounce it a cold substance. In its natural state it abounds in acid properties and produces sorrel. We may render this substance one of the most valuable of manures by suitably preparing it, according to the experience of many farmers. Peat should be combined with some alkaline or basic substance, which will neutralize the acid which prevails in it, and thus supply an abundant nutriment to vegetables. Peat is composed of mosses which grow and then continually decay, giving place constantly to a succession of these sphagnum plants, intermixed with leaves and decayed trees. They abound on the sea-board. Swamp mud resembles peat in proportion to the decayed vegetable matter which it contains; and is adapted to supply the manure we want.

Peat being dug out, another growth of it comes forward, and after a while its place is supplied again. On Block Island, where it abounds, it is used altogether for fuel. In this place the peat contains 98 per cent. of vegetable matter. Our peats contain from 80 to 97 parts of vegetable matter. Swamp mud consists of vegetable matter and earth, making a good manure when its acid properties are neutralized. Several farmers in the neighborhood of Boston have experienced its value. Peat can be substituted by proper management for manure. A distinguished farmer says that farriaging cannot be carried on in his location without peat. Two farmers within his knowledge have mixed three parts of peat with one of stable dung. By mixing it with lime and animal manure, ammoniaical gas is produced, which dissolves the peat and converts it into a powerful manure.

Lime is highly useful in its application to soils. In bone manure it is found in combination with phosphoric acid. The crenic and apocrenic acids unite with it and form manures. All manures before they act, become converted into salts. Soils

are in an acid or neutral state. Large tracts of country, which are now barren, by proper applications might be rendered fertile. A farm within his knowledge, which was a blowing sand, a pine barren, and almost hopeless, on which ten bushels of corn to an acre could scarcely be grown, by the judicious application of ashes, has been made to produce forty to fifty bushels to the acre.

The Dr here illustrated his position by giving the chemical analysis of certain soils in Rhode Island, which it is understood will be presented to the public in his report in a detailed form. Methods should be taken to render the insoluble matter in soils soluble, that it may be taken up by the plants; and it is desirable that this process should proceed gradually. If acidities abound in the soil, correctives must be applied. It is easy to convert one quality of soil into another. The value of geological investigations is not properly estimated.—An analysis of soils is greatly wanted. The statistics of agriculture are greatly wanted. Farmers are not exact in their observation of their crops.—Many valuable agricultural districts are bottomed upon clay. This is desirable in order to preserve the manures which are applied to them. In soils where the manures applied pass through them by infiltration, much loss is sustained; and they are not favorable to agricultural products. This infiltration of manures is doubted by some, but the condition of our wells proves it. The water in a barn yard is never pure. As much as a teaspoonful of vegetable matter to a gallon is often obtained from waters which are considered pure. This may be seen by any one who will evaporate the Boston water to dryness. In the purest water obtained from lakes, 1-2 grain of vegetable matter to the gallon may be obtained. In the water of Boston, 35 grains are found to the gallon. Soils brought from 150 feet depth in this neighborhood, are found charged with vegetable matter.

Land with a foot of top soil on a gravelly substratum may be unproductive. This is the case with the soil on Seekonk plains, which has a foot of soil containing 11 per cent. of vegetable matter; but manures applied pass through it by filtration; and it suffers from drought.

All our waters come from the top soil. Clay is a retainer of water. Bog iron ore is found in soils and is prejudicial to vegetation. There is a ready way for a farmer to test his water. By the application of a solution of lunar caustic to a glass of water, if it contains vegetable matter, it will become red. Distilled water will not exhibit this appearance.

Saline matters abound in soils in the form of carbonates, sulphates and phosphates. Lime is an important amendment to the soil by causing it to furnish nutriment to the plants. It is a chemical reagent and decomposes manures and does not, as has been supposed, form insoluble matters. In the ashes of wheat, lime exists to the amount of 15 per cent. It is found in some proportion in all soils. The carbonate of lime is a valuable amendment to soils and especially to those which contain iron or coppers. Gypsum is a powerful stimulus to vegetation. Lime in the form of a carbonate is easily applied. The management of lime is too generally misunderstood. Fields perfectly barren have been rendered fertile by the use of it. There are few exceptions to this fact in Rhode Island. In some cases its application has been triumphantly successful, and in many cases of failure, the lime has been found to be highly magnesia. There are various

matters connected with these subjects which will furnish excellent texts for discussion hereafter.—The action of manures is particularly important. Science here is of great importance. Certain acids in soils have been discovered by Berzelius. The crenic and apocrenic acids. These are found in the soils of both hemispheres; in the soils of the Mississippi and the Nile. These soils closely resemble each other. The soil of the Nile contains 2.8 per cent. of the carbonate and phosphate of lime. The soil of the Mississippi has less iron and more clay.

The introduction of science into agriculture has been of great benefit. How soils are to be rendered fertile or low corrected, have hitherto been matters of empiricism. We should desire to act understandingly, not ignorantly.

The changes which take place in the progress of the growth of plants, are remarkable. In the germination of the seed, carbonic acid is given out, and oxygen absorbed. After the leaves are formed, they absorb carbonic acid and give out oxygen. When the plant ripens, they give out carbonic acid and absorb oxygen. All manures act on the foliage. If plants are overstrained they fail to produce fruit. It is important to find the proper point or limit of manuring. A distinguished gardener engaged to produce a geranium leaf as large as a cabbage: it was effected, but the plant perished in the effort.

Bleaching powders or chloride of lime, are a powerful manure, and produce astonishing effects on vegetation. The ammoniacal gas or Sal Volatile, operates powerfully upon plants, and this matter is produced by the fermentation of barn manures.

In soils which are porous it is advisable to use manures in a long state. The manures which are obtainable are different in different places. Experiments have been made with bone manure, lime, and ashes, and, as reported, with different results. There are, undoubtedly, differences in soils, which affect their operation. These subjects deserve inquiry and observation. Agricultural observations should be made exact and certain. As the pursuit becomes intelligent it rises in dignity. Why should farmers be ignorant of their great art, when it is the aim and boast of every other profession and pursuit, to study their art thoroughly? Agriculture may be rendered scientific; and science well applied must conduce to render it more profitable.

Facts in these matters are of the highest importance. In Maine ashes were thrown away. The Long Island farmers are willing to send to Massachusetts to obtain them. The intrinsic value or efficiency of the material cannot be affected by the different estimation in which they are held. Peat we see in some places is highly esteemed as a manure. In many places it is utterly neglected; and this can arise only from ignorance of its value or of the proper mode of applying it.

Facts, he repeated, are of the highest importance. Peat in a crude state, is not suited for application to the land. It must be decomposed, and its acidities corrected. A farmer in Rhode Island has made much use of swamp mud compounded with fish, the Menhaden, which are taken in their bays in great abundance. To eight cart loads of swamp mud or peat, he applied one barrel of fish. This compost is denominated fish-pie. The rotting of the fish decomposed the peat and the peat absorbed the ammoniacal gases, which escaped from the decaying fish. The farmer deemed this mixture of

equal value with the best of unmixed barn manure. On a level field, planted with corn at right angles, every row manured with this compost was distinctly observable and was eight times as large as that part dressed with log manure. At the harvest the crop from the rows manured with this compost gave an increase over the other parts of the field of fifty per cent. Any decaying animal substance, on being mixed with it, will produce a decomposition of peat.

The physiology of vegetation is a subject deserving of much attention. The mode in which plants receive their nutriment from the soil is not, as has been supposed, by capillary attraction, but the vegetable food in a liquid form is forced into the minute vessels of the plants by an electric or voltaic agency. This is the discovery of a Frenchman by the name of Detrouchet, and is called by him *endosmosis*. [Dr Jackson here illustrated this matter by a small apparatus.] This operation is at once suspended by the presence of certain substances, such as sulphuretted hydrogen or one drop of fecal matter in the vessel. Acids and alkalis in their combination, act as galvanic batteries and forward the process of vegetation.

The physiology of plants should be studied by the farmer. Innumerable, curious and wonderful operations are continually going on before him. No situation is more favorable than his to intellectual and moral improvement; and no employment more interesting than the contemplation of the phenomena of the natural world.

The green sand spoken of is as difficult of solution as the felspar in granite. In Sweden the carbonate of potash is used to decompose the nitrate of lime, which is formed in their artificial nitre beds, which are similar to compost heaps.—Nitre is produced abundantly in our dung heaps. Many other salts are produced by chemical changes, which are continually going on in the earth and air. The putrefaction of animal and vegetable substances is productive of various changes, and of substances useful in vegetation. The crenic and apocrenic acids are always found in soils, and the degree of their presence when ascertained, will indicate the applications to be made to the land.

The skeletons of all plants and animals have lime for their bases. Silix gets into plants in a manner altogether mysterious. It is found in all plants with hollow stems, such as many of the grasses, in wheat and the cereal grains, in bamboo and flags. The crenic and apocrenic acids operate to dissolve silix. The absorption of plants is not wholly by their roots, but by their leaves, which are the lungs of plants and gather the carbonic acid gas from the air, and its carbon is converted into solid wood. Nature pursues her operations in one eternal round, and all things combine mutually to assist and modify each other. Plants are highly beneficial to life and health, in absorbing and decomposing the elements of the air, and returning that portion which is necessary to respiration and life.

Agriculture is yet to make great advances in this country. The value of peat lands is very imperfectly understood. A farmer in the vicinity of Boston, distinguished for his scientific and practical skill, has obtained one hundred bushels of corn to the acre upon redeemed peat meadows; and obtains from these lands an income of ten to twelve per cent. profit. Land might be cultivated with much more skill and to much higher profit in proportion to the skill applied. Liquid manures among

are almost entirely wasted. Night soil is often thrown away, and yet it is one of the most efficient manures. With all our advantages, we bring Indian corn from Africa, and the country of the Nile furnishes us with pence and beans.

The population of China is immense and supported wholly from the soil. The allowance for a man is indeed small, as three dollars per year will serve to keep soul and body together; but even to earn this, every person does and must work. Among this people agriculture is carried to an extraordinary degree of perfection. With us too large portion of our people are devoted to trade, and the results of rural industry are deserted for the hazards of speculation and commercial life. As we lose our breeds of cattle that we may improve our flock, it would be fortunate if we could so cross our farmers and merchants that the habits of exactness in keeping accounts and the enterprise and spirit of progress which distinguish the mercantile classes, could be in some measure transferred or infused into our farmers.

On the second evening, as on account of the inclemency of the weather on the former evening, my attendance was comparatively thin, Dr Jackson recapitulated parts of his former remarks, and continued and enlarged upon the subject of soils and manures. We shall refer only to those remarks which were not given in the preceding sketch; or which seem necessary to illustrate what was said before.

Great advantages seem to result from the mechanical mixture of soils, as for example, of sand with clay or clay, with sand. This seems to affect their electro-motive power and induces absorption of the plant. Besides the combined acids which exist in soils, there is often much free acid, which requires to be taken up or neutralized. There is much siliceous matter in all soils. The oxides of different minerals abound in soils. These have different electric powers, which require to be understood and regarded. Many soils which have been thought to contain no vegetable matter, have been found upon examination to contain eighty-six tons vegetable matter to an acre. Fields of barren land have been rendered productive by the application of alkaline substances. These soils have been freed, and portions of vegetable matter have been removed by two successive crops. In some soils there is a large amount of vegetable matter in an insoluble state. In this case it must by some operation be rendered soluble, and this can easily be done.

The geological formation of soils is of much importance. A soil with a loose substratum must be much benefited by infiltration. The farmer will find advantages from the chemical analysis of his soils. A gross analysis will not show the differences which exist. It must be conducted with a re-

The Dr here gave another pointed reference to the true state of the well water of Boston, which was felt an electric shock in the abdominal muscles of the representatives from the country; (the Boston gentlemen too far gone in this matter to feel at all), and made me think at once of resigning their seats or removing seat of government. There are salts of lime enough in the water of Boston wells drank every year, to make statues as large as Lot's wife! and as to the other minerals which exist in it, according to the Dr's account, are not to be named. No apothecary's mixture suits it; and we know of nothing for which it is suited for whiskey or brandy punch!

finement of skill and care. The influence of half a bushel of gypsum spread upon an acre of land has been known to render it fertile. It seemed a mere drop in the bucket, yet it produced a surprising difference in the crop. Gypsum has not the same effect on all soils. If the soil abounds in the ingredients which are applied, they are thrown away. If a soil, for example, contains 1.5 per cent of phosphate of lime, it does not require the application of bone manure. So of lime where lime abounds.—The soil of the banks of the Nile, probably the most fertile in the world, contains only 2.8 per cent of lime. The saline manures, such as carbonates, sulphates, phosphates, &c. are absorbed by the plants. They act as stimuli to vegetation; and change the soil so as to render it fertile. Saline manures do not act always in the same way. They act principally on the foliage. They excite action in the plant, and carbonic acid gas is absorbed. The decomposition of vegetable substances gives out carbonic acid gas, which is immediately seized upon by the plants. Large amounts of ammoniacal gas are obtained from the putrefaction of animal substances. This is a valuable manure. The carbonate of ammonia, to obtain it pure from the shops, would be too expensive for a manure. We must make it in our dung heaps.

The nature of manures is just beginning to be understood. The attention paid to it, when science was imperfect, led to few valuable results.—Two new acids were discovered by Berzelius in 1833—the crenic and apocrenic. They were discovered in the Porlar well in Sweden. They are found in all soils. They are among the constituents of peat. They are probably universal. These acids must be neutralized.

The opinions of farmers are often only blind prejudices, though there are bright and honorable exceptions to this remark. Facts which are universally admitted must have a foundation. These acids are found in humus or geine—are found also in our waters—in all soils—sometimes in union with bases—sometimes in a free state. In respect to these scientific investigations, we have as yet only skimmed the surface. More, however, has been effected within the last three years than ever before since the history of man.

Geological and agricultural surveys are creditable to the State. The facts which they collect and embody, may be rendered of the highest service.—A State geologist might be fully occupied in the analysis of soils. Agriculture, thus made the subject of scientific inquiry, would cease to be a drudgery and attain its proper rank among the first employments of man. Agricultural books are many of them full of absurdities, because the nature of the elements of which they treat is so little understood. Many have heard of the experiment of the man who shut up a hen and fed her exclusively upon wheat. It was a matter of insoluble mystery how, under such circumstances, she could obtain lime enough to form the shells of the eggs which she laid, which in truth contained a weight of lime greater than the weight of her body. It was not known that the wheat itself on which she was fed, furnished the lime which she required. Chemistry shows that lime enters into the composition of wheat.

Every farmer has not a taste for science; but some have, and this taste should be cultivated and encouraged. Subjects connected with agriculture are well adapted for country lyceums. Here facts would be obtained from practical and observing

minds. The action of manures should particularly invite attention. Experiments in cultivation should be made on soils whose composition is known; and products should be exactly noted and compared with each other.

De Candolle, a distinguished Swiss philosopher, who has given particular attention to vegetable physiology, has treated of the action of poisons upon plants. There are substances which are poisonous to plants as there are those which are destructive of animal life. *Narcotica* and some other substances poisonous to animals, are poisonous to plants. Substances which taken into the stomach of a man may be serviceable to health, if received into his lungs might be fatal. So substances which if applied to the roots of plants might prove destructive, if imbibed in a gaseous form by the leaves, may stimulate and advance their growth. In simple carbonic acid gas, plants would die; but received in quantities larger than exists in our atmosphere, it proves favorable to them. Carbonic acid gas, which in certain quantities is nutritious to plants, is destructive to animal life.

The quantity of vegetable matter in soils and other different substances, presents a curious inquiry. Silix is the same as rock crystal, obtained after solution. Alumine is the same as clay; but clay is not found pure, and usually contains more than fifty per cent of silix. Oxides of iron, manganese and lime are found. Lime is usually found in the form of a carbonate. Peroxide of iron, iron rust, is found. Silix, alumine, lime and iron, combined in various proportions, constitute soils. Vegetable matter containing the crenic and apocrenic acid is found. Geine is not a simple proximate principle but contains these two acids. [The Dr illustrated this matter by an exhibition of the crenic and apocrenate of copper, obtained from geine.]

The analysis of a clay soil in this vicinity is as follows:

Water,	2.
Vegetable matter,	3.5
Silix and alumine,	74.
Carbonate of lime,	5.
Oxide of iron,	15.
Loss.	.5

100.

Of another is as follows:

Dark clay,	
Water,	8.
Vegetable matter,	14.
Silix and alumine,	72.6
Carbonate of lime,	5.4

100.

To give some idea of the quantity of vegetable matter contained in an acre of ground, we may make the following calculations:

Example of calculation of the weight of a soil and of its manure.

Let the specific gravity of a soil be 1.277—water being 1: then one cubic foot of water weighing 1000 ounces, a cubic foot of the soil would weigh 1277 ounces or 79,187 lbs.

An acre of land contains 43,560 square feet area, and if we estimate the cubic foot of soil as weighing 79,186 lbs. or half a cubic foot at 39 1-2 lbs. nearly, supposing we wish to calculate the weight of an acre of the soil for the depth of six inches, (the usual depth of tillage,) we have the following sum: 43,560×39 1-2=1,719,620 lbs., or 859 tons nearly,

as the weight of an acre of this soil to the depth of half a foot.

If then the soil contain 9 1-2 per cent. of vegetable matter, 2.2 per cent. being soluble and 6.3 insoluble— $530 \times 9 \frac{1}{2} = 100 = 81 \frac{1}{2}$ tons of vegetable matter to one acre within 6 inches depth. Of this 27 1-2 tons is soluble and 54 tons insoluble.

This example is taken from an actual analysis of a soil in the vicinity of Boston. The principles laid down will suffice for the estimation of each and every article found in given soils by chemical researches, and the quantity of manure or of any fertilizer may be easily learned.

Some acres of land upon examination, have been found to contain 91 tons of vegetable matter—some 96 tons—22 of soluble and 72 of insoluble. Excluding stones, we may consider that there are 800 tons of soil to an acre 6 inches deep. In an acre of land, by a calculation of this kind, containing 6.8 of phosphate of lime, bone manure would have no effect.

The peat on the farm of E. Phinney, Esq., used both for fuel and manure, contains 96 per cent. of vegetable matter. The ashes of this peat contains siliceous, alumine, phosphate of lime, oxide of manganese and oxide of iron.

The carbonate of lime, of potash and of soda, acts upon it. The carbonate of ammonia is taken up by it. Lime neutralizes its acid. Peat bogs are composed of sphagnaceous mosses; and on Block Island they are said to renew themselves, after being dug over, in forty years, if the surface paring is returned to the pit when they are dug.

Besides decayed mosses, decayed trees and leaves collect in these swamps and compose a part of the deposit. Peat is of immense value, and not well appreciated by farmers. Experiments of its application in a natural state have proved failures. The farmers on Block Island would not use it. A farmer in Waterford, Me. applied it in a crude state, and his corn was dwarfish and appeared as though struck with the yellow fever. When its acid properties are neutralized, it becomes as valuable as horse dung. Peat bogs must be drained. Covered drains properly constructed, are as effectual as open drains. Peat bogs are remarkable for retaining moisture. Wetness is absorbed by the peat by capillary attraction.

Dr Jackson stated that he had fully described Mr Phinney's method of management, in his third report on the geology of Maine. His meadows are drained. They are then ploughed or the sward inverted; and then dressed with a compost of animal manure, mud and lime prepared in his hog pens, where his hogs earn much of their living by their labor.

On land thus prepared, he has obtained 75 bushels of corn to the acre, and from 4 1-2 to 5 tons of hay per acre. The last season he got a crop of corn of from 80 to 100 bushels per acre. After such land is well drained, he can work upon it with his cattle. He refuses to sell this peat upon this land even at 500 dollars per acre. Being well supplied with peat mud, each hog will make ten loads of manure in the course of the year. This is then thrown out and freely lined. After three weeks' preparation by lime this compost may be applied to the land, at the rate of twenty loads to an acre. About one third of stable manure is deemed the proper proportion to apply to the compost. In the opinion of Mr Phinney and Mr Haggerston, three loads of muck and one load of stable dung are equal to four loads of stable manure.

It is a singular fact that in England peat was

formerly considered as a useless substance. One great use of peat consists in its power of absorbing liquid manures. In barn yards it absorbs the urine. The liquid manure of an animal is considered by many judicious farmers, where it can be well saved and applied, as of equal value as the solid. This subject deserves much attention.

Dr Jackson here closed his address, with some extracts from Young's letters of Agricola, in relation to this subject, the most important parts of which have been given in the Appendix to the Second Report on the Agriculture of Massachusetts, to which we must refer the reader for the present.

The Dr closed with an apology for having detained the meeting so long, and the expression of his thanks for their indulgence. The meeting, he may be assured, were highly gratified and instructed by his remarks, and felt that the obligation was wholly on their side.

We give below an imperfect sketch of the remarks of Judge Hayes, of South Berwick, Me., at the Third Agricultural meeting, and present a similar apology, but can offer no other, for the manner in which they appear, than we gave in reporting the speeches of Dr C. T. Jackson.

REMARKS OF WILLIAM A. HAYES, Esq.

AT THE THIRD AGRICULTURAL MEETING.

Judge Hayes began his remarks by expressing the pleasure he felt in meeting the farmers of Massachusetts; and though he did not anticipate on his coming to town, being called upon in this way, he was happy to encourage an object so valuable as that contemplated by these meetings, agricultural improvement, by giving an account of his own operations and the success which had attended them. Farmers constituted a common fraternity, and as their sole object was the improvement of this important art, whose interests involved the interests and comforts of every class in society, he should make no apology for speaking of plain matters in a plain way. This was the first time he had been called upon to address a meeting of farmers upon the subject of agriculture, and he must therefore claim their indulgence. He had derived so much pleasure from reading heretofore the reports of these agricultural meetings, made by the Commissioner, that he felt it to be his duty when called upon, to contribute his part.

He should first relate his experience in the raising of wheat. He had attempted the cultivation for many years and with very imperfect success. It had been generally destroyed; but whenever he had succeeded, it was always upon high land. In 1838 he purchased of the Shakers, in Canterbury, N. H., one bushel of Black Sea wheat. He sowed it upon an half acre of loamy land, upon which the previous year he had raised a crop of mangel wurtzel; some time previous the land had been manured with muscle bed. The crop appeared very promising but was destroyed by the grain insect, and he obtained a return of only eight bushels. His belief was that the crop was sowed too early. The last year he sowed his wheat much later in the season, and from two bushels sowing on an acre of land, he gathered 41 bushels. His success in this case he considered attributable to his late sowing, owing to which circumstance the wheat did not come into flower until the season for the depredations of the insect had passed. He applied to his wheat land sixty bushels of leached ashes, a matter

which experience has satisfied him is of very great advantage. Like success has attended a similar management in the culture of wheat in other places. He thinks much of the particular kind of wheat sown by him, as he has never known it to be injured by rust or mildew. The kind here spoken of is a red wheat. In the town of Shapleigh, a good ground, the crop on a part of a field sown with common wheat was worthless; while the Black Sea wheat, sown in the same field, gave 52 bushels from one bushel of seed.

On the subject of the evening's discussion, Soil and Manures, he should give his views, founded upon long practice, as he had cultivated a farm under his own personal superintendence, for twenty four years last past. Land in good condition can easily be made better; while lands which are poor and exhausted, are with much difficulty raised up. Various substances may be applied, but the main dependence must be placed upon vegetable matter in and upon the soil. His first object, with a view to enrich his farm, is to collect vegetable matter for litter; leaves and straw and waste substance of every description. He collects leaves even late in the spring, as litter for his styes. These even tend to be small gatherings, but in the course of the season, where this habit of saving exists, the accumulations become very considerable. He is accustomed yearly to mow his pastures and gather at the brakes and ferns and coarse grasses on which cattle will not feed. In this way his pastures are greatly improved. There is a better quality of grass comes in, and the quantity is much increased. He is accustomed, likewise, to mow his stubble grounds. He cuts the weeds and the old stubble close for litter for his stock, and he does not find that his grass is injured by this mowing. He thus collects a large quantity of vegetable waste, and uses in his barn a large basket, which will hold seven or eight bushels, to distribute it as litter to his stock. The great advantages of this management appear in the increase of his manure and the comfort and consequent thrift of his cattle.

He is in the habit of collecting large quantities of swamp mud, which he deposits in his barnyard to be trodden upon by his cattle, and he places large quantities in his hog pens. He suffers this to remain through the summer, deeming it not advisable to turn it over. After keeping this through a winter and summer, he carries it out upon his land. He likewise casts soil into his yard; carries in a large amount of bog mud; the wash of the house, likewise, is conveyed to the same place; and he has always swamp mud on hand to place in the yard that the offensive liquids may be absorbed.— He uses lime, likewise, in his compost heap. For many years he has practiced using from ten to thirty casks per year. He deems it most favorable to health, and as far as the uninterrupted health of a very numerous family may be considered a test in the case, the prudence and benefits of the practice are perfectly established.

A great object with him, and upon which he lays most emphatic stress, is the using of all the vegetable matter which he can collect or apply, for enriching his farm. He never carries his manure out in the fall; and he regrets his want of a manure cellar, as he thinks much would be gained by keeping the manure under cover. He does not deem it necessary that it should undergo a fermentation or decomposition before it is carried into the field. He applies twenty loads to the acre. He begins at

side of his field, and laying eight successive heaps in a row, at the distance of one rod apart, and the rows likewise one rod apart, it will require just twenty times eight heaps to dress an acre. The distance at which the heaps should be placed apart, is ascertained with sufficient accuracy by taking the distance from the hind-end of the cart to the forward feet of the cattle upon the tongue as the measurement of a rod in length. He ploughs his ground about six inches deep, carefully and completely inverting the sod. He seldom ploughs his manure under, excepting where he would raise taprooted vegetables; but having laid his land flat, he spreads his manure and then harrows it and cross arrows it until a fine tilth is produced. His corn is planted three and a half feet apart and is carefully hoed three times without making any hill whatever; and he is careful to suffer no weeds to remain among it. It is suffered to stand in the field until perfectly ripe; and the stalks are not cut until the corn is so far advanced that there can be no advantage from them to the ripening of the ear. His butt stalks also are saved with great care; and when stowed away, his corn fodder being intermixed in alternate layers with wheat straw, the straw itself is rendered more nutritious and salubrious for his cattle. If he plants potatoes, he is careful to plant whole potatoes and of a good size, the sprouts from such are stronger, and the crop is a fortnight earlier. The potatoes are hoed twice and the ground kept clear from weeds.

The second year the ground which has been in corn is not ploughed nor the sod disturbed or re-erected; but it is harrowed in both directions by the cultivator managed by one man with a horse. The wheat is then sowed at the rate of two bushels to an acre, or barley or oats as he may choose, with grass seeds.

He has been in the habit of raising esculent roots for his stock, of the value of which as feed, he has high estimation; mangel wurtzel, carrots, turneps, and ruta бага. He likes the ruta бага very much as a feed for his horses. He planted last year two acres of carrots and ruta бага upon green sward, managed as he has said, and obtained one thousand bushels. Potatoes are sometimes made the second crop in the course. In that case his land has two earings; and so with other esculent vegetable crops.

After haying, and even late in the autumn, he devotes much time and labor to the improvement of his lands. He carries sand on to clay lands, and clay on to sand lands, and finds much benefit from it in intermixture of soil. He deems the principal advantage resulting from this process, to be upon land which he cannot plant, the covering up of all vegetable matter on the soil, by which means becomes rotted and improves the staple of the soil. This he deems a matter deserving particular attention; this covering up of vegetable matter and converting it into manure. He pursues this work even until late in the autumn, when the ground is frozen.

He obtains much swamp mud. He has extensive meadows, which have two and a half feet depth of mud resting upon blue clay. He has attempted the redemption of this land by digging a centre ditch three feet in width and two feet in depth, and cross ditches at right angles with the main ditch, and emptying into it. These cross ditches are two and a half feet wide at top, 18 inches at the bottom and one foot in depth. They occur as often as once in two rods. After the

ditching is completed, gravel or sand is carried on to the meadow at the rate of one hundred loads to the acre and manured. It is then sowed liberally with herds grass and clover. The ditches require to be cleared out once in three years, and the matter collected in them spread upon the land. In this way they may be kept in good condition for an indefinite period of time. His own improvements in this way are of twelve years' duration and without deterioration.

In 1838, he undertook the redemption of four acres of this kind of land. He covered it with gravel, which was spread immediately. The next spring when the ground was thawed to the depth of two or three inches, he harrowed it most thoroughly; he then sowed herds grass and followed it with a bush harrow. The crop of grass which he has since obtained from this land was at least two tons to the acre; and the moss in the land was completely decomposed.

He is accustomed to use alternately his pastures as mowing fields and his mowing fields as pastures. He finds a very great advantage from this course of management. He ploughs his pastures, even though he has no manure to apply to them; and though he cannot fence them against his cattle. He inverts the sod, laying it completely over; and then sows his grass seed. In this way the feed of his pastures is greatly improved both in quality and quantity. He ploughs his pastures, getting a crop of Indian corn and then laying down his land with Indian wheat and grass seeds. The Indian wheat, i. e. the Tartarian buck wheat, is deemed by him a good crop, and the flour much esteemed. When he has no manure to apply to the land, he ploughs it in a shallow manner; but, at any rate, it should be occasionally ploughed and sowed with grass seed.

Judge Hayes has done much in the improvement of his live stock, having obtained an improved Short-Horn bull from Greenland, N. H., where this valuable stock has been some time reared, and from which the beautiful ox Columbus was descended, an ox whose superior is seldom seen.

He closed his remarks much too soon; but he has kindly promised that we shall soon hear from him on these subjects—an engagement which he cannot too soon fulfil. We shall hold him strictly to his word in this case; and being a lawyer, and knowing the consequences of neglecting "to take up one's paper," we mean to sue him if he does not pay the note at maturity.

The account he has given of his farming operations so far, will be read with much interest and instruction. His improvement of his pasture lands deserves particular attention. We have often urged it upon farmers; but he is the only man we have yet known to practice it.

II. C.

HINTS ON THE CARE OF HORSES.

There are a great many farmers who take but poor care of their horses in the winter season. In the short days they have water before dark, and then have to go without until nine or ten o'clock the next morning, or if they have water early in the morning, they will not usually drink, as their time of thirst is past. Horses seldom refuse water after they have eaten their evening meal, though if they do not have it then, they will usually drink but little the next morning until after eating. So if a horse will not drink early in the morning, it is

no indication that he has not been thirsty the previous evening.

We have been particular in our observations on this point. We have turned a horse out to drink at nine or ten o'clock in the evening, and seldom knew him to fail of drinking heartily. Then for experiment, we omitted to give him water in the evening and attended to it in the morning before he was fed, and he would seldom drink. If it be best for animals to have free access to water at all times, as is generally allowed, then they ought surely to have a supply immediately after eating, when they are usually thirsty; though the superficial observer who finds that they will not drink early in the morning, may think that all has been well.

There is not a man probably, who has not at times been very much in want of drink, and yet, without being able to obtain it, his thirst has gradually abated. In this case the juices from other parts of the body are, in a measure, put in requisition, to supply moisture when it is wanted, so, by an equalness, the thirst is abated or done away, but there is a deficiency of moisture in the system—a drought less severe but more extensive, which if experienced daily, will prove unfavorable to health and strength; and in animals it will injure the growth of the young and operate against the fine, healthy condition of every creature. They must have water when they need it, or they will not drink; like men, they do not eat and drink according to fashion and custom.

Some farmers will use their horses till they are warm and sweaty, and then put them up, perhaps, in a cold barn, without covering them with any thing to keep them warm. This is often greatly increased by allowing the horses to drink freely of water while warm, in order to save the trouble of watering them after they have stood till cool: a great many horses suffer in this way, and some are ruined. For a man or beast to be inactive and exposed to cold after exercise and perspiration, is very destructive of health, and will destroy the strongest constitutions. Every man knows the importance of guarding himself against exposure to cold after perspiration, and how a drink of cold water in this state, will send a chill through his whole frame. Though a man is not like a horse, he resembles him in his ability to endure a great deal of labor, with proper management, and in his liability to disease if his tender frame be not guarded with care.

It was observed in the Farmer some months ago, that it was better for a horse to have a place in the winter where he could stand upon the manure, and walk round at ease, than to be confined to a stall and stand upon a hard floor. But in this case, as the horse will generally stand in one place to eat, the manure will accumulate under his hind feet so that he will stand uneasy, unless it be levelled frequently, so that it will be as high or higher under his fore feet.

Currying horses is very much neglected by some farmers. This operation is very important, as it contributes both to the pleasure and health of the animal. In some cases this business is hardly attended to, being performed only a few times in the course of the winter.

Many a farmer's horse that is now stupid and lazy, and of a miserable appearance, would, under the care of a good hostler, without extra keeping, become so changed in his appearance and spirits in a few months, that his owner would hardly know him.

—Maine Farmer.

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, FEBRUARY 12, 1840.

REPORT ON BEET SUGAR PREMIUMS.

The Trustees of the "Massachusetts Society for the Promotion of Agriculture," impressed with the consideration of the important advantages that might be derived as well for the benefit of the agricultural as of the manufacturing interests of the country; and being also aware that the attention of many eminent men in several foreign countries has been zealously devoted to this subject, whereby great improvement in the production of the beet and the manufacture of sugar therefrom was in progression; were thereby induced in their proposals of premiums the last year to offer as follows, viz:

"To the person, persons or corporation who shall raise the greatest quantity of sugar beets by the acre, not less than two acres, which shall be manufactured into sugar in the year 1839, giving a particular account of the soil and the manner of sowing, cultivating and gathering the beets, a premium of *One Hundred Dollars*."

This premium was not claimed, although the principal objects aimed at by the Trustees, viz: the soil best suited, the manner of cultivation and ingathering of the beets, are fully made to appear in the application made for the next proposed premium, having relation to the same subject, which was as follows, viz:

"To the person, persons or corporation who shall manufacture from the sugar beet, (denominated Silesian white beet), sugar in the greatest quantity and of the best quality, in the year 1839, giving a full and particular account of the process of manufacturing it, a premium of *One Hundred Dollars*."

For this premium there was only one claim preferred, which was from the Northampton Beet Sugar Company, by their agent, David Lee Child, Esq., who presented two several samples of common brown sugar of the usual flavor of such low priced commodity. An excellent sample also of loaf sugar, a very bright color, well grained and crystallized, and no wise inferior in appearance to the best loaf sugar manufactured from the cane. The sugar of each quality was carefully examined by the committee. It was also inspected as made use of in different articles of confectionery, by one well conversant in the art (Mr Duroy,) who commended each sample, considering it as fully equal to sugar of the like quality from the cane.

There were also two samples of molasses one of which appeared to be of good flavor and quality, and it was thought well suited for those purposes to which this well known article is applied for domestic use or for the Bakery.

The article of second quality may be used for the distillery, or for various gross purposes as well as in aid of the vinegar cask. Its properties are also thought well of as nutritive for animals.

The whole process of sowing, cultivating, ingathering and preserving the Silesian white beet, considered as the most replete with saccharine matter, and of course most suitable for manufacture, with remarks on the soil best suited for production, and a full and particular account of the whole course of the manufacturing the beet sugar through its several processes, are very minutely set forth in a pamphlet of 150 pages. This work of careful research, the committee are led to expect, will hereafter be so far abridged as to diffuse a more general knowledge than might otherwise be had.

For the several wished-for objects thus brought into notice, the community are indebted to the praiseworthy en-

terprise of the Northampton Beet Sugar Company, and the assiduous application and zeal of their agent, Mr Child.

The measures thus taken in this establishment may, it is hoped, lead to a course of experiment and improvement which may, if persevered in, lead to their benefit as well as that of the public.

The Northampton Beet Sugar Company, having produced through their agent, Mr Child, the requisite certificates as to the quantity and quality of beet sugar manufactured by them, and the same having been carefully examined and found to be severally of good quality, as herein represented, and having, also, submitted a full and particular account of the whole process of the manufacture, the committee were induced to report that they are entitled to the premium of one hundred dollars.

It may be considered, perhaps, incumbent on the committee, in closing this report, to state some facts which the treatise furnished, in connexion with this subject, will, if referred to, more fully show.

The cost of the brown sugar as manufactured, appears to be from 5 to 6 cents per pound. In France, where nearly one hundred millions of pounds are said to be annually manufactured, being about three pounds to a person, labor, generally, is much lower, and a great part of it is performed by women and children; it is done, too, at a rate less than half what is paid here. This, as far as labor is included in the calculation, would add essentially to the cost of the sugar. There are, however, circumstances which are reasoned upon in this communication, which go far to counteract these disadvantages, viz: the cheapness of fuel, rent, buildings, &c.

The value of the pulp, too, or residuum of the beet may be of great advantage, if well distributed, in the feeding of cattle, swine, &c.

There is, in conclusion, one important object to be hoped for from the great efforts which are making in Europe as well as in this country, that the research and experiments now in exercise, may conduce to a more simple process, by which the manufacture of beet sugar may be availed of by domestic industry. This is by many confidently anticipated.

It is, however, much to be regretted, that this desired object has, in this respect, thus far, wholly failed.

All of which is submitted in behalf of the Committee.
JOHN WELLES, *Chairman*.

BOSTON, 1839.

THE FOURTH AGRICULTURAL MEETING

Was holden on Thursday evening, 6th inst., Mr King in the Chair.

The meeting proceeded to elect four vice presidents and an additional secretary. The following gentlemen were chosen vice presidents:

- Mr Otis Brigham, of Westboro';
- " B. P. Williams, of Roxbury;
- " C. P. Phelps, of Badley;
- " Jesse Pierce, of Stoughton.

Mr Henry W. Cushman, of Bernardston, was chosen additional secretary.

The Commissioner then proceeded to exhibit to the meeting a butter presser, for the purpose of expressing the buttermilk without applying the hand to the butter. This was invented at Nantucket, and had been sometime used there by the inventor, who greatly approved it. It is a simple machine, somewhat resembling a baker's brake.

A turnip quarterer or slicer, simple and cheap in its construction and effectual in its operation. This he had obtained in the interior of New York, and commended it to the use of the farmers.

Next a sample of superior winter wheat, sent him from Halifax, under the name of Chevalier wheat, or Brown's prolific. It is a soft-skinned winter wheat, and eminently beautiful.

Next, samples of raw silk from Dr. Deane, at Great field, reeled upon a simple machine of his own construction; on his part a first attempt at raising silk; in this case a perfectly successful attempt.

Next, specimens of raw silk, of a beautiful quality from Northampton, Mass., and Burlington, N. J., made from the leaves of trees planted the last April. Next beautiful specimens of sewing silk, manufactured at Northampton and at Harvard, Mass.; and next, a superior specimen of black silk velvet, and seven different specimens of elegantly wrought wide ribbons; the silk grown on the articles manufactured by Miss Grotzsch, Rapp, & Economy, Penn.; a lady who receives this year for her products more than four hundred dollars, in bounty from the State.

Lastly, a box of butter, recently made, and without any artificial coloring whatever, sent to him from the farm of Mr C. Denny, of Westboro', and manufactured by Mrs Blake. It is of a fine color and flavor, as if manufactured in June, and done up with the greatest neatness and care. The Commissioner has often urged upon farmers in the vicinity of Boston, to keep winter dairies as the trouble would not be greater than in summer, as new butter of the best quality would at that season command the most liberal price. He has been constantly met with the objection that butter of a good consistent color could not be made at this season of the year. He was happy to show this butter, as demonstrating the error of this prejudice; and the admiration which it excites, will not, it is hoped, be lost upon the farmer. Almost as many penknives were drawn out to taste it; Burke says, swords would have flown from their scabbards in behalf of the beautiful French queen. The swords would have been for defence: the penknives were for attack; and the Commissioner thought himself fortunate that he was able to maintain the citadel unharmed.

The meeting was then addressed, at the invitation of the committee of arrangements, by the Hon. Isaac Hix, ex-governor of New Hampshire. The subject of his address was the Improvement of the Agriculture of New England. He went largely into a view of the improvements and present condition of husbandry in Great Britain, and showed in what respect their modes of husbandry were applicable to our country. The address was received with much gratification by a crowded assembly. It was interesting, instructive, and useful. At this time as will be seen from the state of our columns, we have no room even for an abstract of it. This will be given hereafter.

The Fifth Agricultural Meeting will be held at the Representatives' Hall on Thursday evening next, at 6 o'clock. The subject of discussion—Indian Corn.—H.C.

A CARD.

The Commissioner of Agricultural Survey respectfully acknowledges the receipt from Messrs Ellis and Besso of this city, of a sample of Spring Wheat called *Ely's Gigantic Wheat*; deemed highly prolific. It is single early fruit.

From George Randall, Esq. of New Bedford, a sample of Spring Wheat raised on his highly improved farm at Rochester, Plymouth County—a very fine grain; a sample of Winter Wheat grown on the same farm, and quite fair a sample of Chevalier Barley, recently imported, and heavy and beautiful article; and a sample of Wheat from Orleans County, New York, very good, with which his own will not suffer by comparison.

From Messrs J. Breck and Co. samples of Winter Wheat denominated *Surry Golden Drop* and *Wingtop* Wheat, both winter grains; and samples of *Hopetown Essex Winter*, Kent Tartary, and Dutch Poland Oats and of tares and beans, from a lot selected by Mr Webster in his recent visit to England; and without doubt among the best which could be found. The wheats are remarkably beautiful, and the oats very fine samples.

These several articles will be exhibited to the farmer at the next agricultural meeting.

HENRY COLMAN,
Commissioner of Agricultural Survey

TO CORRESPONDENTS AND READERS.—The communication from Mr Warren on the Rohan Potato shall appear in our next.

☞ We trust it needs no apology that we have given our readers in our paper of to-day, so much of a good thing. We did not like to divide the speeches, and we know they will be read with instruction and pleasure.

BRIGHTON MARKET.—MONDAY, Feb. 10, 1840.

Reported for the New England Farmer.
 At Market 347 Beef Cattle, 600 Sheep.
Prices.—Beef Cattle.—Our quotations last week first quality should have been \$7 00 instead of \$5 00 as reported. We quote this week First quality, \$6 00. Second quality, \$6 25 a \$6 75. Third quality, \$5 a \$5 75.
Lamb and Calves.—Very few at market and no sales had.
Butter.—Owing to the large number at market last week prices did not much advance. We quote lots at \$1 00, \$3 00, \$3 75 and \$5 00.
Wool.—None at market.

THERMOMETRICAL.

Reported for the New England Farmer.
 Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded and early exposure, week ending February 9.

Feb., 1840.	7 A.M.	12 M.	5 P.M.	Wind.	
Monday,	3	8	23	30	N. W.
Tuesday,	4	1*	4	2	N. W.

- White Tankard do.
- Purple Top Hybrid.
- Red Globe Mangal Wurtzel.
- White do.

have also received some of the Early Hope Cabbage which was tried last year at New York and proved to be superior to any Early Cabbage hitherto known in the State.

have now in New York, which will come to hand in a few days, some of the Chevalier Barley, which we shall be glad to offer to our customers.

It has been understood by some that the seeds were left for gratuitous distribution. We wish to correct this as it is not the case. We were directed to dispose of them at a small advance, sufficient to pay for our trouble, &c.

JOSEPH BRECK & CO.

Feb. 12, 1840.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO. at the New England Agricultural Warehouse and Seed Store, Nos. 51 and 52 North Market Street, have for sale, Green's Patent Straw, Hay and Stalk Cutter, operating on a mechanical principle not before applied to any implement for this purpose. The most pronounced effects of this application, and some of the consequent peculiarities of the machine are:

1. So great a reduction of the quantum of power requisite to use it, that the strength of a half grown boy is sufficient to work it very efficiently.
2. With even this moderate power, it easily cuts two bushels a minute, which is full twice as fast as has been claimed by any other machine even when worked by horse or steam power.
3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.
4. The machine is simple in its construction, made and put together very strongly. It is therefore not so liable as the complicated machines in general use to get out of order.

AGRICULTURAL BOOKS

JOSEPH BRECK & CO. offer for sale a great variety of Agricultural books, among which are the following:

- Loudon's Encyclopedia of Gardening.
- " of Agriculture.
- " Suburban Gardener.
- Forbes Hortus Woburnensis.
- Practical Agriculture, by David Low.
- Chaptal's Agricultural Chemistry.
- Hogg on the Cultivation of the Carnation and other Florists' Flowers.
- The Florist Cultivator.
- Lidgeman's Gardeners' Assistant.
- Fessenden's American Gardener.
- " Complete Farmer.
- Kenrick's Orchardist.
- Manning's First Book of Fruits.
- Sagers' Fruit Garden Companion.
- " Flower Garden Companion.
- Treatise on Sugar Beet, by David Lee Child.
- American Swine Breeder.
- Mowbray on Poultry.
- Monography of the Genus Camellia.
- Dennis' Silk Manual.
- Cobb's do.
- Kenrick's Silk Growers Guide.
- Whitmarsh on the Mulberry Tree and Silk Worm.
- American Farmer.
- Parley's Cyclopaedia of Botany—The Young Florist.
- Weeks' Treatise on Bees.

ELEMENTS OF PRACTICAL AGRICULTURE.

Just received, a supply of the Elements of Practical Agriculture, comprehending the cultivation of plants, the husbandry of domestic animals, and the economy of the farm. By David Low, Esq. F. R. S. E., Professor of Agriculture in the University of Edinburgh. Second edition, with numerous engravings: 71s. pp. London published. For sale by JOSEPH BRECK & CO., No. 51 and 52 North Market Street. February 5.

FLOWER SEEDS—CHOICE VARIETIES.

JOSEPH BRECK & CO. have received a choice assortment of Flower Seeds from England and France, which, in addition to what have been raised under their own inspection, embrace the finest collection to be found in the country, including all the new Annuals, Biennials, and Perennials worthy of cultivation; neatly done up in papers at 6 1-4, 12 1-2, and 25 cents each. For sale at 51 and 52 North Market Street. February 5.

FOR SALE.

An excellent Farm, pleasantly situated about 20 miles from the city, containing about 100 acres. For full description, particulars, &c. inquire at this office.

Also, a situation wanted by a man with a small family to carry on a farm.

MISCELLANEOUS.

THE MOLE.

The strong, short legs of the mole, the palmated feet, armed with sharp nails, the pig-like nose, the teeth, the velvet coat, the small external ear, the sagacious smell, the sunk, protected eye, all conduce to the utilities or to the safety of its underground life. It is a special purpose, specially consulted throughout.

The form of the feet fixes the character of the animal. They are so many shovels: they determine its action to that of rooting in the ground; and every thing about its body agrees with this destination. The cylindrical figure of the mole, as well as the compactness of its form, arising from the terseness of its limbs, proportionally lessens its labor; because, according to its bulk, it thereby requires the least possible quantity of earth to be removed from its progress.

It has nearly the same structure of the face and jaws as a swine, and the same office for them. The nose is sharp, slender, tendinous, strong; with a pair of nerves going down to the end of it. The plush covering, which, by the smoothness, closeness, and polish of the short piles that compose it, rejects the adhesion of almost every species of earth, defends the animal from cold and wet, and from the impediment which it would experience by the mould sticking to its body. From soils of all kinds the little pioneer comes forth bright and clean. Inhabiting dirt, it is of all animals the neatest.

But what I have always most admired in the mole, is its eyes. This animal, occasionally visiting the surface, and wanting, for its safety and direction, to be informed when it does so, or when it approaches it, a perception of light was necessary. I do not know that the clearness of the sight depends at all upon the size of the organ. What is gained by the largeness or prominence of the globe of the eye, is width in the field of vision. Such a capacity would be of no use to an animal which was to seek its food in the dark. The mole did not want to look about it, nor would a large advanced eye, have been easily defended from the annoyance, to which the life of the animal must constantly expose it. How, indeed, was the mole, working its way under ground, to guard its eyes at all? In order to meet this difficulty, the eyes are made scarcely larger than the head of a corking-pin; and these minute globules are sunk so deeply in the scull, and lie so sheltered within the velvet of its covering, as that any contraction of what may be called the eye-brows, not only closes up the apertures which lead to the eyes, but presents a cushion, as it were, to any sharp or protruding substance which might push against them. This aperture, even in its ordinary state, is like a pin-hole in a piece of velvet, scarcely pervious to loose particles of earth. Observe, then, in this structure, that which we call relation. There is no natural connexion between a small, sunk eye, and a shovel, palmated foot. Palmated feet might have been joined with goggle eyes; or small eyes might have been joined with feet of any other form. What was it, therefore, that brought them together in the mole? That which brought together the barrel, the chain, and the fusee in a watch, design; and design, in both cases, interfered from the relation which the parts bear to one another in the prosecution of a common purpose.

COCOA NUT TREE.

The tree attains a considerable height in those places which are best suited for its growth; and it grows on those sandy soils which are not so well adapted for the culture of other useful vegetables. Like the rest of the palm family, the cocoa-nut tree is without branches; but the trunk consists of a tissue of remarkably tough fibres, that intersect each other like net work, and thus the tree can bear those violent storms and hurricanes which are so frequent on the Indian shore. The middle rib of the leaves is often ten, twelve, or fourteen feet long, and is very firm and strong. The leaflets are very numerous, of considerable strength and very durable. These leaflets are not only used for the manufacture of baskets, but are an important article in Hindoo architecture, being plated together to form the roofs and walls of houses, of which the trunks, when split, compose the beams and rafters. The flowers come out at the roots of the leaves, in long sheaths, of which there is a considerable number upon a vigorous tree. When the flowers have nearly attained maturity the sheaths upon the male flowers drop off, the germs begin to expand into nuts, and after they have attained a considerable size, the sheath also shrinks up. The fruit, when it approaches maturity, is very large, far larger than the nut which is imported into this country. It consists externally of a hard brown rind, which is very thin and tender; within that, there is a great quantity of brown fibres. This fibrous matter, which is known by the name of *coire*, is of great use to the natives. When short, it is used for the same purpose as basked hair in this country, and cushions stuffed with it are very elastic. It is also spun into cordage of a very superior quality, and there have been many instances of vessels riding out storms securely by coire cable, when the best heupen ones, of European manufacture, have failed. The use of the cocoa-nut shell, as a vessel, is well known in this country. It is one of the most firm and durable of vegetable substances, and requires very little preparation to make it fit for use. The pulp of the nut, though rather indigestible when used alone, is a favorite ingredient in many Indian dishes. It also yields a great quantity of oil, which is used in India for the lamp, and for many other purposes.—*Picture of India.*

PRINCE OF WALES AND MAJOR NORTH.—North was an aid-de-camp to the Baron Steuben, Inspector-General of the Revolutionary Army. After the peace, he made a trip to England, where, being a sensible, witty young man, he was introduced into good company. At a party, where the Prince of Wales was present, (the King then laboring under his first malady) Major North was called on for a toast. Forgetful, for a moment, of that property which had distinguished him, he unguardedly proposed, "A speedy coronation to the Prince of Wales." The Prince immediately discharged his glass of wine in the Major's face; who, with great self-possession and ready humor, threw his own in the face of the next guest, exclaiming, "Pass it round—'tis the Prince's sentiment." This was a serious beginning turned into a jocular end.

"I was charmed," said Lord Oxford, "with the answer of a poor man in Bedlam, who was insulted by a boy because he would not tell him why he was confined. The unhappy man at last said:—'Because God Almighty has deprived me of that which you never had!'"

VEGETABLE CUTTER.

Willis's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and esculent roots fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public; they are aware that it has been long wanted and they offer a machine that cannot fail to give satisfaction upon fair trial. It will cut with ease from one to two bushels a minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at Agricultural Warehouse, 51 and 52 North Market Street, December 18. JOSEPH BRECK & CO.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that good bones form the most powerful stimulant that can be applied to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and charge for casks or carting.

Also, ground Oyster Shells.

Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse & Seed Store, No. 52 North Market Street, or through the P. Office will meet with prompt attention.

NAHUM WARD

SCIONS OF FRUIT TREES FOR SALE.

The collection of fruits cultivated at the Pomology Garden consists of more than 1400 varieties of the Apple, Pear, Plum, Cherry and Peach. Scions of all those which have been proved are offered to nurserymen and others. Gentlemen wishing to send collections of American fruits to their friends in Europe can be furnished with most of the first rate quality. They are warranted true to their name and are in all cases cut from fruit bearing trees. Salem, January 28, 1850. ROBERT MANNING.

A MAN WANTED.

To do the work on a small place, a few miles from the city. He must understand the cultivation of vegetable fruits, &c., and the care of horse, cows, &c. A single month 20 to 30 years of age, of steady and industrious habits may inquire at this office. J. B. L. January 15.

AMERICAN SWINE BREEDER.

Just published and for sale by JOSEPH BRECK & CO. the American Swine Breeder; a Practical Treatise on Selection, Rearing, and Fattening of Swine, by Henry V. Ellsworth; price 75 cents. January 15.

ROTHAM POTATOES.

For sale at the New England Agricultural Warehouse & Seed Store, No. 52 North Market Street, at 85 per barrel. October 16. JOSEPH BRECK & CO.

SCIENCE APPLIED TO AGRICULTURE.

Chemistry has been styled "the secret process of the matter, that from which the forms of things emanate." It is a science as universal in its operations as the combination of different simples in forming compound substances. Hence, the air we breathe, the earth we walk upon, the rain that comes down from heaven and watereth the earth, the food we eat and the raiment we put on—in short, every thing, not only those which render our existence comfortable, but those which form its enjoyment, are the result of its operations and subject to its laws. Even ourselves, "fearfully and wonderfully made," a curious compound of undefinable energy, mind, and perishable, incongruous matter, within its sphere, and possess enough of its "mysterious agencies" to invite the research of the most persevering to an occupation for life. In fact, we live in a grand laboratory, where chemical action is continually going on, not in a single set of them, but a stupendous whole, and where it will continue to go forward, until the mass of matter on which it operates shall, by a grand explosion, be hurled back to chaos. Mind truly may exclaim, "The trophe of ruin, and the clayey crucible in which it experienced its remodeling and assimilation; but in all things else the amalgamation must complete.

It is for a moment to be imagined that a science of general operations and such visible effects, is unimportant to a farmer? Take his soils; they are the result of a chemical combination of elements, say the disintegrated parts of rocks and vegetable matter in a decayed or decaying condition. All rocks, as the sciences which claim more molecular kindred with them will determine, are composed of the same material, consequently the particles which collect around them must differ in proportion as the sources from which they originate, and the early productions of vegetation are as the peculiar nature of the earths most nature excites, and these possessed again of different elements in their decay, both of leaves, and the parent stalk has fulfilled its maturing process. Soils of varieties differing from those are the effects of different circumstances. A soil on which the dark hemlock sheds its foliage, differs from that which sends the tow-hipine majestically high: that of the maple from the ash; the oak from the elm, and so

Soils in high regions have usually less depth and are a proportionably greater amount of earthy matter than those of lower territory, from the fact that vegetable matter is easily brought down by the laws of spring and rains of autumn, and deposited in places which nature seems to have provided for its reception. These soils are usually of the most fertile character, yet they must in some degree, vary in proportion with the mountains and

forests whence they originate. Thus we see the valley of one river more fertile than that of another—a circumstance which chemistry can obviate, by determining what the lacking quality is, and how it may be provided, or introducing plants adapted to that peculiar soil. The analysis of soils, sufficient to determine their productive qualities, is a very simple process, and soon passed through. In order to perform it, the farmer need not be at expense for an extensive apparatus, nor restrict his operations to drams and pennyweights. His business is of a *wholesale* nature; his observation can mark the changes of soil, and by analyzing a small portion of a particular one, the character of the whole is sufficiently determined for general purposes.

Soils which in a state of nature, are sometimes of a character which renders them worthless, by a chemical process are rendered fertile. Take our swamps, which are to be found in almost every town, some of which have bottoms as deep as western prairies, and "as rich as mud": yet in a state of nature they are almost as worthless as the desert of Sahara for agricultural purposes. How are they to be made the most profitable of the farmer's domains? They must be cleared and drained, to be sure; but when all this is done there is yet one thing lacking, for they are as barren as an ash-heap. What is "the one thing needful"? We respond, not only to show that *chemistry* has a remedy, but also to assure those who pretend that our State surveys are useless operations, by giving an anecdote.

Somewhere in Massachusetts, (we could tell where,) an old gentleman who had tilled the earth carefully and laboriously, until his "threescore years and ten" had nearly vanished, pointed the Commissioner of the geological survey to a piece of very deep rich muck land, and complained bitterly that with all his industry, he could make it produce nothing but weeds. With his usual tact, the Commissioner assured him the only reason why his labors were not requited, was that his land was *too rich*. "Too rich!" said the veteran farmer, "it can't be: we wish to make our land as rich as possible, and labor incessantly to promote this object." Had he been acquainted with the beautiful operations of chemistry, how it applies itself to every part of the operations of agriculture, he might perhaps have saved himself much labor, and a rich harvest from his land through many years. More, by the same labors he might have increased the value of his surrounding fields, by bartering from them their sterility, and repaying load for load from the rich deposit of his muck bed. This was all that was necessary to scatter fertility all around him—simply to carry off this rich vegetable matter which had been accumulating for ages, and replacing in its stead his sands or loam, or whatever that savored of barrenness.

Lands from mismanagement may acquire a diseased and sickly as well as an exhausted state.—They may become too sour, too bitter, or some other of the evils which bad management induces, may attack them. Then are they like a diseased stomach, totally out of order. Usual applications will

have no effect. They, like the sick man, must be dealt with according to the disease. And here we ask leave to introduce another anecdote, in support of our sentiment that chemistry is an important science for the farmer. One of that ancient and honorable fraternity was one day heard to complain by a son then in college, that such a piece of land produced but "*litle*." "Lime it," said the son. "Lime it!" said the old man, "you, when you have not done a day's work on the farm in three years, come from college, and to repay your father's toil in your behalf, undertake to teach him how to farm it!" "Lime it," said the son—"the soil is too sour: an alkali will neutralize an acid, and your field will be productive." The father at length tried the experiment, and saw a good effect, and so thoroughly was he convinced of the utility of this science in agriculture, that he said his sons might all go to college to learn to be farmers, if they all give assurance of similar acquirements.

Chemistry in agriculture applies itself in a thousand ways and produces a thousand good effects.—Nature is a great workshop, where she is continually carrying forward her operations. Economy is a universal law in all her dominions. She wastes nothing in vain, and where the purposes of its formation are answered, and it moulders back to decay, she does not admit of the least waste in all its parts. She carries out with the nicest precision, the salutary injunction, "gather up the fragments, that nothing may be lost." Hence what is not available in one part of her operations, is applied to another; and so in her grand concerns, each fits a "part of the stupendous whole." To imitate and assist her in carrying this law into effect, is a part of the service of the farmer, and in proportion as he does his duty, will his labors be rewarded. But if he is remiss, if he allows his soils to remain sterile or suffers them to become exhausted—if he allows his manures to waste their richness on the atmosphere, or suffers them to be injudiciously applied to his lands—if he suffers any thing to waste uselessly away, which with due care might benefit his soil, leanness will set a landmark to his possessions which his neighbor will not try to remove; famine will enter his premises, and the horrors most likely seize upon his mind.

W. B.
Mount Osceola, Jan. 27, 1840.

For the New England Farmer.

ROHAN POTATOES.

Brighton, Jan. 28th, 1840.

MR BRECK—Dear Sir—Much has been said and written about the Rohan Potato, and much, I think sir, which has had a tendency to mislead many as to its quality and productiveness.

I have waited till I supposed all the "Great Yield of Rohans" had been giving to the public before I dared give you an account of the experiment I made the last season, and which I had promised to give you some time since.

The object I had in view, sir, in making these experiments, was not to see how many pounds I

could grow from an ounce, or to ascertain how many bushels I could obtain from a pound, using extra soil, manure, labor, &c. &c.

But my object was to find out what kind of soil and manure was best adapted to the Rohan, and what might ordinarily be effected by common care and means.

I now give you as briefly as I can, the promised account.

I purchased of you in May last, five pounds Rohan: on the 7th I selected the lowest ground I had, a very deep soil, rich but very wet: I marked out one row of fifteen hills, about two feet apart: I dug with a spade, holes below the level surface, about one foot deep: into these holes I put two quarts each of Ward's bone manure, and mixed it up with the earth, nearly filling the holes to each hill: I planted two eyes and covered them three inches deep: the ground was so wet while planting as to mire and make it quite muddy.

I next planted fifteen hills more, in a row parallel with the first, (three feet distant.) The second row was planted precisely like the first, excepting the manure. To this row I applied fresh cow manure, and mixed it up with the earth in the holes as the first. To each row of fifteen hills I planted two pounds of Rohan.

You will recollect, sir, that about this time we had heavy rains: after they were planted, the water actually covered the entire surface of the ground for more than two days; it was so very wet, I doubted much if they ever sprouted. On the 15th I planted the other pound; and for this I selected the driest ground I had, a side hill, having a north-easterly exposure: I planted ten hills: manured with old stable manure (horse.)

To all the three rows I gave but the ordinary care, removing the weeds between them twice only, and giving them a very slight hilling up.

Those planted on bone manure came up first and grew best: those planted on the cow manure, only six out of fifteen came up at all: those on the horse manure all came up.

On the 24th September, the day previous to the annual exhibition of the Massachusetts Horticultural Society, I dug them all.

From the fifteen hills planted on bone manure I dug two bushels, very large and superior, weighing 128 lbs.: From the six hills that came up on cow manure, the produce was about a peck, weighing 12 lbs.; inferior in size and appearance: and from the ten hills on the side hill, I dug half a bushel, weighing 30 lbs.; very fair in size and appearance.

I have tried the several kinds on my table, and find those grown in the meadow, on the bone manure, decidedly best; yet I do not think them by any means a good eating potato.

Those grown as above mentioned, on the bone manure, were long and large, many of them weighing over a pound. I selected twelve for the exhibition at the Society's rooms, which weighed 14 lbs.

Those grown on the side hill were smaller, more round, and even surface.

From the experiment I made, I am satisfied that the Rohan will prove a very desirable potato for stock. That wet land suits them best, and to ensure great crops, bone manure is what they crave. These are my reasons:

When I dug them I was struck with the appearance of the long, fibrous roots, which had struck down into the bone manure, and formed, as it were, a perfect net-work around the whole mass, so much so, that in pulling up the tops or vines, the whole

mass in some instances were drawn up with them, and this only with those planted on bone manure. I took particular notice of this fact, for in digging the others I found no such roots at all.

The bones were decomposed in part and formed a glutinous body, and it appeared that it had absorbed and dried up much of the moisture around the hill, and it is to this fact I attribute their preservation during the wet season, their rapid growth and their liberal produce, while the other row near them were nearly or quite destroyed by the moisture.

There is no doubt in my own mind but that the crops would have been much larger had they remained longer in the ground, for when they were dug they were in a thrifty and growing state; but being desirous of ascertaining some facts at that time, was the reason of my digging them.

So well convinced am I, sir, that the above mentioned facts are important, that I shall the coming season, increase the quantity planted to several bushels, and upon bone manure, and should any one be induced to try the experiment, I hope they will give the result to you.

Very respectfully,

Yours, truly,

JAMES L. I. F. WARREN.

Brighton, (Vouantum Vale,) Jan. 28, 1840.

For the N. E. Farmer.

PAUPER FARMS.

MR BRECK—The system of supporting the poor on farms, is one that has added much comfort to the unfortunate, but is opposed by some individuals on the ground of expense. It has appeared to me that such farms should be model farms. Managed judiciously, by men who should be retained in office for a series of years, they could be made such.

The manner of presenting the annual accounts of many pauper establishments, of the kind here referred to, has appeared to me erroneous, and conveys to the inhabitants wrong impressions and results in cheating the farm of its rightful due, in the same way that farms are frequently defrauded by individuals. Below you have a supposed case, presuming that the town has paid for its farm and stock, and that without it, the cost of supporting each pauper would be ninety cents per week, as struck off to the lowest bidder.

April, 1839.	Farm,	Dr.
Cost of farm,		\$3000 00
Stock,		300 00
Tools,		125 00
Produce,		495 00
		<hr/>
Paid cash for oxen,		\$3920 00
“ “ blacksmith,		100 00
“ “ wheelwright,		22 40
“ “ I plough,		10 60
“ “ clothing, groceries, &c.		6 00
“ “ for inmates,		171 80
“ “ superintendent,		300 00
Interest on \$3920,		235 20
Estimated labor of inmates,		78 00
Balance profit,		285 00
		<hr/>
		\$5129 00

	Farm,	C
By cash for butter, &c.		\$3200
“ “ Calves, &c.		20
“ “ Potatoes, &c.		40
“ “ Boarding inmates, average number through the year 19, at 90 cents per week,		885
1840—April.		
Farm,		3000
Stock,		320
Tools,		113
Produce,		5129

By the above it will be seen that the town, posing its farm as good as the previous year, made an advance of \$285, and has paid the interest on investment, \$235, making the sum of \$520 which deducted from \$885, the cost in the old of supporting the poor, leaves the actual cost of the town \$369;—or say \$19 1-2 per year, or 37 cents per week for each person, supposing the number nineteen.

It is confidently believed that the results of favor of the pauper establishments prove more favorable than represented above. Will you or some of your correspondents point out any error that may be in this statement.

CHANGE IN ENGLISH HAY.

MR EDITOR—In the spring of some eight or ten years ago, (I am not certain of the exact time,) the working oxen, which had previously been very good to bear the heat in the spring, could not work usual, without being over-heated. On inquiry I found that other farmers' oxen were in the same situation, and that it was very extensively so. It was a subject of inquiry and discussion, what could be the cause, as the weather was not unusually warm. My oxen had always in the spring, been kept on hay, of what is called natural English mowing, and always before, with the best success. The natural English mowing is meant such upland is too rocky, or too moist to plough, or which is supposed to be more profitable to remain in its natural state; and occasionally giving it a top-dress of fine manure, and in that way to get two crops of hay in a year, and a third, of good feed for cattle. Why it is called English hay, I know not for such grasses are the natural product of the soil.

After much thought on the subject, and from the fact that my cows were affected in the same way when exposed to the sun, I came to the conclusion that it was the hay; and most men now have come to the same conclusion; not all, however, being aware of the fact, that the quality of the hay is altered, and that, from some unknown cause, somewhere the management has been the same for a long succession of years. It has now become very generally known that this kind of hay is not so good as well by animals as formerly: there is not so sweet smell to it that there used to be, and that generally causes the cattle that eat it to heat.—In some instances, the cultivated grasses are not of so good a quality as formerly, and produce the same effect as the natural grasses on working oxen. Now what can be the cause of this alteration in the above mentioned kind of hay? I will hazard the opinion that it is caused by some alteration in the season.

you, Mr Editor, or some other one, tell us if can, the cause of this change?

A FARMER.

Jan. 27, 1840.

ESTING CAPITAL IN AGRICULTURE.

At the present time when there is much derangement in commercial concerns, and when the world is filled to a surfeit, with all kinds of stocks, it may not be improper to pause a moment, look around us and see what sort of investments have been made, the tests which the various circumstances of critical and commercial nature have brought to upon them. Is that portion of capital which is invested in the thousand and one speculations of the day, as safe and as productive as the holders suppose? Do the banks exhibit in their returns, an enormous dividend that makes their stock very lucrative that it is an object to invest in largely? We think not. If we take the amount of bank dividends in this state and compare them upon the amount of capital stock, it will hardly amount to four per cent. Look at various other kinds of fancy or other stock, we have swallowed up so much of the capital of our own citizens—very few of them yield six per cent. Again, look at the active commercial part of the community. Group them all together and run up the profits and the losses, and average among the individuals, and will their profits be great and so splendid that it would be cause for envying the proprietors? So unsettled has become business, and so full of uncertainty and fluctuation, that hundreds and thousands, who have entered the field of commercial enterprise with little capital—the fruits of their own or their fathers' industry—are now in fact deeply insolvent, and truth penniless, however well they may appear in concealing it by the use of other property.

How is it with capital invested in agriculture? How is it with funds invested in the soil? Are improvements of a well managed farm? Are they any more productive, or are they, in fact in the back ground as the votary of constant speculation would fain make the world believe.

We believe that if we take the amount of capital invested in any well conducted farm, and carefully calculate the net proceeds, it will be found that it is more productive than most of the investments of the present day. Let us take for example, any particular crop. The oat crop is as good as any as to calculate upon.

Let us first estimate the amount of capital to be invested in a crop from an acre; and first we will give an estimate of this state may be considered a large price, especially if we were to purchase a whole farm at this price, we will give \$30 for the acre,

we will give the straw for harvesting and thrashing, we have now invested fifty-seven dollars and fifty cents.

we will suppose that you get thirty bushels of straw and that is a crop hardly worth bragging of. Our friend Ford, of Gray, gets 66 bushels of straw, but we will take thirty bushels, only thirty, and sell them for less than we gave in the market for seed. We will sell them for 37 1-2

cents per bushel, which will amount to \$11 25. Now eleven dollars and twenty-five cents is the interest of \$187 50, at 6 per cent, or in other words, is more than nineteen per cent upon the interest of capital invested, including purchase money and all. But as you have the acre still on hand, deduct if you please, the \$50 which you gave, and the expenses will then amount to \$7 25.

This then is the actual floating or circulating capital required to produce your acre of oats, including rent or interest of purchase money, and the net income, \$11 25, is about 155 per cent.

Fiddletick, exclaims neighbor Scrubard—now this is all humbug—real book farming. Any body can get rich on a piece of paper. If money can be made so easy by farming, why ain't I and every one who have been farming all our days as rich as mud? I don't believe nothing on 't.

Well neighbor, put down your goodstick and let us inquire into it. How large a farm have you? One hundred acres.

What did you give for it? \$2000, that is \$20 per acre. The interest of this is \$120. Well then I have to pay about \$20 in taxes, that makes \$140, then I have to hire help, two men six months in a year, and work hard myself the year round.

Well we will give you all twelve dollars per month, that will be \$144 for yourself, and \$144 for your men; equal to \$288, which added to the interest and taxes, \$140, makes \$428 outsets or circulating capital. Then there is the interest on the cost and wear and tear of tools, you have reckoned. Well we will give you \$72 to pay for that, which is the interest of more than a thousand dollars for your tools and implements, but we will give you that sum, which added to the \$428 will swell it up to \$500. Now how in the world do you pay this \$500 but off of your farm?—mind you, this \$500 is what you invest, year after year—it is the interest of your first investment of \$2000 for your farm, payment to yourself and men for labor, &c. &c. Now how much land do you cultivate and how much hay do you cut?

I cultivate twenty-five acres, and mow twenty-five—I have twenty-five in pasture and twenty-five in woodland.

Produce.	
2 acres of Indian corn,	50 bush. worth \$50 00
1 " potatoes (light crop)	1000 " " 200 00
5 " oats	150 " " 56 25
6 " barley	120 " " 80 40
5 " wheat (light crop)	50 " " 50 00
3 " rye	60 " " 60 00
40 tons of hay worth \$6 per ton	240 00
Total	\$736 65

Thus the whole amount of your crops are worth \$736 65, making due allowance for rust in your potatoes, and weevil in your wheat, and not rating the other very high, either in amount per acre or at a high valuation in the market. We have charged you nothing for seed, and although we have allowed you full wages while sowing, cultivating and harvesting, we have said nothing in regard to the value of the straw, husks, &c. You have thus realized \$236 65 more than a return of your circulating capital, which is more than 47 per cent.

Alh, well—this looks mighty well on paper, but it is n't cash. The merchant and the broker have the clean cash, while we poor farmers have to go without the rhino, if our barns and cellars are ever so full.

What then? it is what will purchase cash—it is property, it is substantial wealth. If you were under the necessity of buying this amount of produce in the market's, you would find that it was worth something. Scrubard looked somewhat puzzled.

It is true, said he, it would cost a good deal to buy what even a poor farmer may raise; but after all, where is one that does as well as you have figured out, there are ten who run astern and finally come out of the little end of the horn.

Grant you that, neighbor, and what is the reason of it? They do not invest capital enough in their business, either because they have not got it, or because they are too penurious. They may cultivate a few acres well, which yields them a good profit, while they suffer nine tenths of the rest of their farms to lie idle, and the interest on the cost of these acres eats up the profit of the few that they do cultivate. We have said nothing of the income from your pasture or your woodland.

If the position here taken be true, and we challenge scrutiny, and beg to be put right if we are wrong; how much better would it be if those who are now farmers by profession would, if able, devote more capital to their business instead of diverting it as many do into other channels and engaging too largely in other business.

Any one who rides through the state cannot but notice the thousands of unimproved acres on either hand. How much better would it be if more of our young men would take hold of the business of farming, instead of aspiring to a life of apparent ease in commercial pursuits. It is true that the farmers crops are sometimes cut off; but not oftener than are the hopes of the merchant. Mildew and hail and rain, and hurricanes sometimes destroy the fruits of the earth; but not oftener than do the elements work destruction upon the ships of the importer.

Life is full of vicissitudes, and risks and changes in whatever place or pursuit you can engage, but, taking every view we can of the whole, we are convinced that capital invested in agriculture is most safe and profitable.—Maine Farmer.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Feb. 8, 1840.

E. W. Bull, Esq., of Hartford, Ct., exhibited specimens of a large, handsome, red sweet apple. Mr Bull states that they were the produce of a natural tree, which the past season yielded 30 bushels of apples.—We should judge from its size, beauty and tender and sweet flesh, and its abundant produce, to be one of the most valuable winter fruits. Mr B. has kindly offered to send some cuttings from the tree in the spring, which will be distributed to the members of the society.

Mr Oliver exhibited beautiful specimens of the Eclairerie Pear, (London Hort. Soc. Cat. No. 308.) This fruit although of small size, is very high flavored, not subject to crack or blight, an abundant bearer and deserves to be extensively cultivated.

Mr French exhibited three sorts of Red Winter apples—names or origin unknown.

Mr Manning exhibited specimens of the Easter Beurre Pear. For the Committee,

ROBERT MANNING.

The mechanic who is ashamed of his apron or the farmer who is ashamed of his frock, is himself a shame to his profession.

For the N. E. Farmer.

BENEVOLENCE IN BIRDS—THEIR USEFULNESS, &c.

The communication of H. C. in the Farmer of the 5th inst., relative to the canker-worm, in which he says the only effectual remedy against these insects known to him is "the encouragement of birds," brings fresh to our recollection some reminiscences respecting this persecuted, interesting and useful race, which we think will be pleasing to our readers, particularly to the younger ones. We can hardly say with the writer of the article, that "killing a small bird should be placed in our penal code next to killing a child"; but we do say that it ought to be met with a punishment sufficient to prevent the destruction which annually takes place, in mere wantonness or sport, among the innocent songsters of our groves and orchards. We have been almost disposed in times past to bring the boys before Judge Lynch, and might probably have done it could we have put our hands upon them.

While residing in Lancaster a few years since, we were located near the river which runs through the town, whose banks and intervals are ornamented with numerous fine elms and other trees, which add much to the beauty of this pleasant village: in these trees the birds congregate in great numbers and rear their young. A gigantic elm, the admiration of travellers and the pride of the village, threw out its wide spreading branches over the cottage in which we dwelt, and while it shielded us from the scorching sun, afforded in its ample head, (a forest almost in itself,) a secure retreat for a great variety of birds, whose movements afforded much amusement for the family. Among these birds were a pair of crow black-birds, who had selected the fork of a partly decayed limb very high in the tree, as a place to build their nest and rear their young. Having in my juvenile days some prejudice against this bird, as I was taught, that with the crow it would dig up the newly sprouted corn, and commit sundry other depredations, I therefore viewed them with a suspicious eye as I saw them in company from day to day upon my newly planted grounds, busily engaged in helping themselves to what they liked best. I satisfied myself soon, however, that they had been vilely slandered, and that they were friends and not enemies: it was evident they were clearing my grounds of grubs and worms at a great rate. They soon found that I was no enemy to them, and consequently became quite tame and familiar, following the plough or harrow with nearly as much confidence as the domestic fowls. It appeared that there was a good state of feeling among the numerous tribes that inhabited the tree, consisting as they did of so many families, embracing the robin, blue-bird, sparrow, golden robin, and a variety of others, and things seemed to prosper among them, and go on well, until the night before old fashioned "lection," (a fatal day to the feathered tribe): during that night there was a very high wind: early in the morning I was awakened by an unusual clamor among the birds, and rose to ascertain the cause—I found that the decayed limb on the fork of which was the crow-black-bird's nest, had been broken off by the wind, and the nest and contents (five young ones,) precipitated to the ground, and that four of them were dead or dying. The surviving one was nearly fledged and could fly a little. I picked it up from the grass and placed it in a secure situation, supposing the distressed parents would take care of it. The old ones continued their clamor all the morn-

ing, which with the sympathizing cries of the other birds, formed a melancholy concert.

While the black-birds had perched upon a neighboring tree near the road, still giving vent to their sorrow, a boy passed with his gun, fired, and brought them both to the ground and carried them away in triumph: luckily for the boy, I did not witness the barbarous deed, but it was noted by one of the family and soon reported to me. As I had become somewhat interested in the unfortunate orphan, I proposed to my children that they should feed it with worms until it could take care of itself, and accordingly placed it in a pen under the tree and returned to my work near by. It was not long before I heard from the young bird its peculiar note which it uttered when its parent brought food, and on looking up, saw that it had hopped up on to a joist to which the board fence was fastened, and to my great delight and surprise, beheld a blue-bird in the act of feeding it. That beautiful passage of scripture flashed upon my mind—"Are not five sparrows sold for two farthings? and not one of them is forgotten before God." My curiosity was now raised to see what would be the issue, and I soon found that any further care on my part would be superfluous, for the young chap had fallen into better hands. It was with the deepest interest I watched the movements of this devoted pair of blue-birds to their adopted one, for it appeared that both male and female had taken part in this work of disinterested benevolence and devoted themselves with unremitting attention to its wants, until it was able to take care of itself. For a couple of days it remained near the spot where I first saw the birds feeding it, and being near a window, had a good opportunity to see how things went on between them. It appeared that the young one kept his benefactors pretty busy; for their incessant labors could hardly satisfy the young gormandizer, as upon an estimate after much attention, he received a portion of food every 2-2 minutes during the day, which appeared to consist of worms and grubs. The black-bird probably weighed twice as much as both blue-birds, and when it opened its capacious mouth to receive the food, it seemed as though its kind friends were in imminent danger of being swallowed whole. The blue-birds appeared alternately with the food and lit down a few feet in front of the bird on the fence, and viewed with apparent astonishment, the extended mouth of the young one for a second, then hopping up deposited the food, then as quick back to the first position, regarding for another second with marks of satisfaction, the object of charity, and then away for a new supply.

In a few days the young bird found the use of its wings, and was followed from tree to tree upon the premises by its faithful providers, for nearly a week: it had by that time learned to find its own food; and soon it fell in company with some of its own kind and kin, and I could recognise it no more. Whether it ever returned to express its gratitude to its foster parents, we have never learned.

Many of my neighbors could testify to the above facts, as some of them called daily to see for themselves.

J. B.

CONTENTMENT.—Contentment inclines us to good actions. Innocent pleasures, also have a healthful influence upon the body and mind. As melancholy and grief wear away our strength, so is it proportionally increased by cheerfulness and joy.

From the Boston Courier.

BIRDS—CANKER WORMS.

MR EDITOR—I see it stated in your paper of Friday, that the probable reason why the canker-worm commits small ravages in 'Flob,' is found in the care with which the birds are protected. I was reminded of a remark in Peabody's Life of Wilson: "He enters into a deliberate calculation of the exact value of the services of the red-winged black-bird, which certainly bears no good reputation on the farm; showing that, allowing a single bird fifty insects in a day, which would be short allowance, a single pair would consume 12,000 in four months; and if there are a million of pairs of these birds in the United States, the amount of insects is less by twelve thousand millions, than if the red-wing were exterminated." Let any one during the brooding season of robins or of other birds, rise by break of day and count the number of times old ones return in one hour with worms and insects, or, if he can let him count through the day, and the number will be found to be almost incredible.

The practice of killing birds for mere amusement, is not merely indicative of cruelty and want of feeling, but is exceedingly detrimental to the interests of the community. If the farmers reflected and made calculations upon the subject, they would discourage and oppose it as one of the greatest scourges, and would pay a premium to their boy to let the birds alone rather than furnish them with powder and shot to kill them.

And, now that I am upon the subject of insect and worms, let me add that there is a very unreasonable prejudice against toads. They are exceedingly valuable in gardens and other places, in consequence of the exterminating warfare they are continually waging against the bugs and worms. Any person who has them in his garden has a treasure there; and if he will watch them closely, he will find them accomplishing more in the way of preserving his squash and cucumber vines and other vegetables, than he can do with all his troughs of liquid. I think these subjects will be brought more fully into notice by the gentlemen commissioned by the State to examine its Natural History; indeed know that one of them, at least, has been at great pains for two years, to collect from all parts of the country what information he could upon the subject, which would be likely to secure the farmer from the ravages which his trees, his grain crop, and all the products of his farm suffer from insect and other causes. I would suggest that this subject be brought up at the weekly agricultural meetings, and that persons acquainted with these matters be invited to communicate their information upon them. For, notwithstanding all the outcry about retrenchment and useless offices, it seems to me that no offices are likely in the end to be more valuable to us than those which will bring to light the hidden resources of this State, and collect a the information, both scientific and practical, which will secure to the agricultural population relief from every thing which blights and diminishes their crops.

S. Y.

It is moral excellence alone that renders a free people great and happy. Without it, all is empty splendor and hollow decay. Religion is the source of most of the moral excellence of the race. Influence when pure and liberal, is wholesome and ennobling.

For the New England Farmer.

EDUCATION OF FARMERS.

MR BÆCK—In your notice in the New England Farmer of the highly cultivated and productive arm of that very useful and distinguished gentleman, E. Phinney, Esq., of Lexington, you remark that he assured you that his attention was first called to the subject of agriculture by reading the New England Farmer, and that at his establishment you realized all you had expected to see, where the science of agriculture, guided by the hands of learning and practical skill, was brought to the aid of practical farming.

This recalled to my mind a subject of vast moment, not only to the agricultural interest of the United States, but to every interest and craft into which human society is subdivided: I mean a radical defect in our whole system of education, from the common school upward to the final graduation at our colleges, during the whole of which important period of human life, the attention, the taste, the sympathies of the educated class are systematically diverted and estranged from the subject of agriculture and the pursuit of the great mass of our people, as if an evil spirit rather than a good and merciful God, had first assigned to man the cultivation of the earth as his highest and noblest pursuit—as if to keep up the humbug importance of the learned professions, as if the statesman, the scholar, the lawyer and divine, need know nothing of care nothing about agriculture—the pursuit, perhaps, of sixteen twentieths of our population, and why which all classes “live and move and have their being”; as if national wealth, independence, happiness and morality, had nothing to do with the increased products of the earth.

Now, sir, how comes it to pass in this boasted public, of almost boundless extent, of every variety of climate, soil and production, that the principle of equality is entirely reversed—that which is now takes the precedence of that which is substantial—that he who lives by professional quackery, the honest chieftains of trade or gambling speculation, is admitted by common consent to a higher rank in the public estimation than the farmer? I answer, our system of education lays permanently the foundation of this very state of things. Admit the science and art of agriculture to an equal importance in our institutions of learning with chemistry, architecture, law or theology: let it be considered one of the sister sciences, and let stated lectures be delivered to our young men during the period of their collegiate education, on the science of agriculture as on chemistry, comparative anatomy, or oriental literature, and a new day would dawn on the agriculture of the country and the condition of the husbandman. When these young men go forth through the length and breadth of the land to exert that influence upon society which begets alone to education and intelligence, to direct public sentiment, make laws and rule the land, in the walks of private life, in the halls of legislation, agriculture would find warm and hearty friends and staunch and bold advocates in the learned class, and grants and aid from the States would be as common to agriculture as they have been to learning, law, medicine or theology; and the now unwarped donations for agricultural learning, would come as common, and more honorable and useful in the foundation of professorships of Greek, Latin, oriental or polite literature.

Is not agriculture as much a science as law, medicine, theology, or moral philosophy? Is there not as much in agriculture to form a good, useful, and virtuous character in our young men, as in the discussion and lectures on mere abstract morals or modern literature?

Had our legislators of the present day enjoyed the benefit of agricultural lectures in the course of their education and been made early in life to realize the importance of agriculture as the true source of national wealth and independence, can you believe for a moment that by a partial system of legislation, predicated on the superior claims of commerce, the mechanic arts and manufactures to State and national encouragement, they would have made the country dependent on the monarchies and despotisms of Europe for the supply of their daily bread? Is not our republic, by the annual importation of from 15 to \$20,000,000 of bread stuffs, reduced to the condition of a farmer spending annually more than his income, and in case of foreign war, unbalanced and diverted from its true and natural channel, as the industry of the country now is, must not famine and distress invade many portions of our glorious and now happy country?

It is said by some that the idea of an agricultural professorship is Utopian and visionary. Other countries have found it necessary to enlist learning on the side of agriculture. In despotic Russia, in the colleges at Petersburg and Moscow, are agricultural professors at the expense of government, and in the common schools and colleges in Prussia, agriculture is a part of the regular course of studies: In the German states, in France and Scotland, similar attention is given to agriculture.

Now, we have public spirited men among us with untold thousands, designed at last for some public benefaction, to perpetuate the usefulness and beneficence of its present owners, after they shall have passed from the scenes of this mortal life to the rewards of the just made perfect. Now what object to such men can be presented, with higher claims to their beneficence, than agricultural education? Very respectfully, your ob't serv't,

H. C. MERJAM.

PRESENTATION OF A VASE TO M. P. WILDER, Esq.

MR EDITOR—It will, I have no doubt, be gratifying to your floral friends to learn, that soon after the close of the splendid exhibition of dahlias, by Col. Wilder, Messrs Hovey, Breck, Low and others, at the room of the Massachusetts Horticultural Society, in September, and at the Conservatory at the Botanic Garden in Boston, in October last, it was proposed by a few admirers of this gorgeous flower, to present Col. M. P. Wilder with some token to testify the pleasure they have received (in common with thousands of their fellow-citizens for several years past,) by the brilliant displays which he has so repeatedly made. The subscriber, Chairman of the Committee on Flowers of the Massachusetts Horticultural Society, was requested by the contributors to procure a silver vase, and to present the same in their names, to Col. Wilder: this has been done.—The vase was manufactured by Messrs Jones, Lows & Ball, in their best style, and bears the following inscription. The insertion of these few remarks in your valuable publication, with the letter of Mr Walker and the reply of Col. Wilder, will oblige many of your readers.

Yours,

S. WALKER.

Roxbury, January, 1840.

Inscription on the vase:—“*Consequitur quodcumque petit.* Presented to Col. M. P. Wilder, by a few friends, as a memento of his unrivalled specimens of the dahlia, exhibited at the Conservatory.”

On the reverse side—“*Boston, October, 1839.*”

“To Marshall P. Wilder, Esq.”

MY DEAR SIR—A few friends, admirers and cultivators of the dahlia, anxious to express to you, in some other way than words, how much they have been gratified by your splendid exhibition of the Dahlia, (and more particularly so by your specimens exhibited at the Conservatory, in October last,) have requested me, in their names, to prepare some token, as a memento of the high estimation in which they hold your successful cultivation. That memento is herewith sent you.

No event, sir, could have given me greater pleasure than being permitted by your friends to join with them in this humble tribute of respectful consideration and regards for your success and future personal welfare, and to subscribe myself, in their behalf,

Your ob't, humble serv't,

S. WALKER.

Roxbury, December 7, 1839.

“To Samuel Walker, Esq.”

MY DEAR SIR—Your very polite letter, accompanied with the beautiful silver vase, is received.

I should do great injustice to my feelings, were I not forthwith to express to you, sir, and to your associates, how fully sensible I am of the honor conferred on me by this distinguished testimonial of your approbation.

If I have done any thing to advance the interests of horticulture, the reflection, in itself, would be ample reward for all my exertions; but that I should, in the opinion of gentlemen so well skilled in the science, have attained, in any degree, to such success as to merit the motto you have caused to be inscribed on the vase, or the kind sentiments expressed in your letter, is more than I could have anticipated; and I must attribute this need of praise rather to feelings of friendship than to any deserving of my own.

Be pleased, sir, to receive for yourself, and to communicate to the gentlemen associated with you, my most heartfelt acknowledgements for this token of their esteem; and to assure them, that it will be carefully preserved as a treasure during my life and transmitted to my family as a memento of our mutual love for the productions of Flora.

Wishing you all great success in the delightful pursuits of horticulture, and happiness and prosperity in all your concerns, I subscribe myself, with sentiments of great respect,

Your obliged, but humble servant,

MARSHALL P. WILDER.

Huathorn Grove, Dorchester, Jan. 1, 1840.”

Riches.—It is a strange delusion for men to suppose that happiness consists in riches. Contentment is not to be found in splendor and magnificence; or why is it that princes have sometimes exchanged the grandeur of a palace for the more simple enjoyments of private life? Why is the countenance of the rich man furrowed with thought and anxiety, while the poor go on their way shouting and exulting in the blessings which God has given them? Why does the man who has grown in wealth, look back to the days of his poverty, and ask himself why he cannot now rejoice as heartily over the much as he did over the little?

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, FEBRUARY 19, 1840.

THE FIFTH AGRICULTURAL MEETING

Was held at the Representatives' Hall on Thursday last. The attendance was large, and there was no abatement of interest in the objects of these meetings.

The Commissioner presented to the meeting several specimens of spring and winter wheat, of oats, barley, and tares, which were much admired.

The Chair then announced the subject of the evening's discussion to be Indian Corn.

The Commissioner then proceeded to give some views of the importance of this crop to the State, and the produce per acre which had sometimes been reached. In Pennsylvania, on five acres of land in the same field, one hundred and twenty bushels of corn in an acre had been produced. In New York State, at Whitesboro, near Utica, more than 170 bushels had in three several instances been produced on an acre. In our own State, in Essex county and Middlesex county, more than one hundred and sixteen bushels. In Plymouth county one hundred and thirty six bushels, as measured at harvest on the cob, and one hundred and ten bushels, as measured in the succeeding March, after being shelled. He likewise had the pleasure of giving them an account of a crop grown the present season in Southbridge, by Dr Samuel Hartwell, which yielded, as was certified in the most respectable manner, one hundred and fifty and one-half bushels upon one acre, one rod, and four rods of land; this would exceed one hundred and seventeen bushels per acre. The Commissioner then proceeded to read the statement of Dr Hartwell, giving all the particulars of his cultivation, the nature of the soil, the mode of manuring and plowing; and to exhibit a sample of the corn grown.

After this, Mr Allen Putnam, of Danvers, and Mr Wm. Clark, of Northampton, members of the House, and Mr H. C. Meriam, of Tewksbury, and Mr James G. Carter, of Lancaster, proceeded to address the meeting in a full and instructive manner, in regard to their modes of cultivation and the uses and value of the product.

Mr Putnam considered the value of Indian corn, as food for man and cattle, and pronounced it one of the most profitable crops which could be grown; he referred particularly to his farm in Danvers. The comparative value of different crops will vary of course in different situations. The soil of the farm on which he resides is heavy and gravelly. The depth of the loam is not uniform; in some parts it is black; in others it is heavy but not wet.

Formerly, the practice on the farm was to put ten loads of manure to the acre, and this was placed in the hill. A good crop at that time was forty bushels. Fifty would have been considered very large. The crops now are much more than that, and this increase comes from an increase of manure and improved cultivation. The kind of corn planted and which has not been changed on the farm for years, resembles what is called the Brown corn. It was formerly an early, now a late corn.

The crop obtained on the farm in 1839 was at the rate of 72 bushels per acre; in 1855, 60 bushels per acre; in 1837, 35 bushels of ripened corn and 37 bushels imperfectly matured, but not weighed; in 1836 the crop suffered more than in 1837, but in this year he was absent from home, and he must therefore leave it out of the account. The crop has been cut off three times only in 60 years, viz: in 1766, '36 and '37. In 1835, the yield was 95 bushels per acre; in 1851, 75 bushels per acre. Through the years enumerated then, the crop has averaged 65-25 bushels per acre.

The expenses of cultivating an acre were estimated at 73 dollars; allowing in this case 40 dollars for manure. The value of the corn fodder was estimated as equal to one ton of hay, 15 dollars. It would be right to allow one third of the expense of the manure for improvement, as its advantages would extend beyond the first crop.— Charging interest upon the land at 100 dollars per acre at six dollars, and including every expense, the net profit of the crop would be \$25 63. The same as for a profit can be generally obtained on any cultivation.

His mode of cultivation is to spread ten to twelve loads of manure in the autumn and plough it under. In the spring he would apply the same quantity to land which for any circumstance he could not plough in the fall. He is accustomed to plough from 6 to 8 inches deep. Though

they have made repeated observations, they have not been able to perceive any difference in the crop on land ploughed in the fall or in the spring. In the spring he applies from his compost heap or barn cellar, 25 loads more of manure, which is put into the hill. The land for planting is furrowed both ways at right angles and at a distance of 34 feet apart. The large crop of corn referred to was obtained on land newly broken up, and which had been some time in pasture. His crop the last year was injured by a severe storm, which checked the filling out of the ear, and the crop was 87 bushels 19 qts. per acre. Corn planted in hills at 3 ft. apart, gives 4300 hills to an acre.

When corn is planted on land upon which the manure is spread, it seemed at one time "to come to a stand." When the manure had been placed in the hill, it advanced rapidly. In July, however, the corn on the first named land, came up with that on land on which the corn had been manured in the hill.

His corn is harvested by being cut up and "stocked." Three hills form a bundle; four bundles a stook. In the cob, the corn weighed 83 1-2 lbs.; shelled 60 lbs.

Mr Clark, of Northampton, followed Mr Putnam. His object was not by extraordinary cultivation to obtain the largest crop which could be grown; but to obtain the best return for the time for the labor and capital employed.

His experiments in the cultivation of corn had been made upon light and worn out soils, pine plains; and his great object was to bring these lands into grass. His own experience had taught him that Indian corn was the best crop for this purpose. He should find it difficult to say what he would on this case, because the cultivation of this crop involved many points on which he would gladly enlarge, but the limits of the occasion did not admit of it. The best time and preparation of the land, were matters of great importance.

Farmers should seek instruction. They should endeavor to understand why they obtain a crop, and all the circumstances which must combine for the success of their husbandry. They apply expense—of time, labor and capital. Labor itself is capital. Unless they can understand the reason why labor is effectual, and what mode of applying it is best, they cannot apply it to advantage, and much that is applied will be necessarily thrown away. Labor constitutes the great expense of cultivation. Results are the effects of causes. We must seek to understand the causes, and we can then to a considerable degree, determine or modify the results. From the want of this knowledge, misapplied labor becomes money thrown away.

In proportion to their estimated value and the cost of cultivation, more may be obtained from light lands than from any others. Corn, as he had stated, was the best crop for bringing them into grass. Oats are an exhausting crop. Oats and rye and the small grains, are of the same character as grasses. They exhaust the land of that principle which is congenial or necessary to grass. On this doctrine is founded the necessity for a rotation of crops.

He has obtained corn upon these light lands without any manure at all, by taking advantage of the vegetable matter contained in them. Cold heavy lands require much manure. Light lands are cultivated with much less labor. They are, in his opinion, favorable to grass. These notions are opposed to prevailing opinions. He will not assert positively that moist and heavy lands are not, strictly speaking, more favorable to grass, but light soils, in his opinion, are of grass, and the amount is greater or the return better, than upon heavy lands, when the expense of manure and labor in the two cases are compared.

Ploughing is a most important operation in reference to the productiveness of the land. Differences of opinion in this matter prevail among farmers. Some prefer laying the furrow sward upon each other, or as it is termed, lapping them. He prefers to lay the furrow slice as flat as it can be laid. In this way he would cover up all the vegetable matter which was on the surface, that it may be effectually excluded from the air; and the progress of decomposition go on with as little waste of substance as possible. The proper depth of ploughing is matter of controversy. The first Stimpson, of Galway, in New York, cultivated the most successful farms in the country, ploughs not more than three inches. He does not approve this shallow ploughing. He has tried it and was unsuccessful. He now ploughs from 6 to 8 inches in depth, where the depth of soil admits of it. He goes as deep as the loam, but objects to bringing to the surface the subsoil. He disapproves much of what is called the "cut and cover" system of ploughing. He would have the whole surface completely inverted and well cultivated. This thorough

and careful ploughing gives a better result. Farmers find more often in ploughing than in any other agricultural operation. If it is not done well at first, it is difficult afterwards to correct faults or remedy deficiencies. If patches of sward are left untouched by the plough, he causes them to be turned by the hoe. He straightens his furrows, and is careful to leave every thing smooth. At the time of ploughing, these corrections can be made at a saving of a quarter of the labor which would be required to accomplish it afterwards. After this is done, he is careful to pass over his fields with a roller, and completely settles the furrow so as to cover up all the vegetable matter which was on the land. The difference between this and the usual modes of ploughing, is very striking in the results. The roller he considers very indispensable. If the land is not rolled, the grass will grow up through the furrows, and the sward will not be rotted. His crops sometimes reach thirty to forty bushels per acre. He has sometimes obtained these crops without manure. On these light lands, if he can have but one, he prefers a roller to manure. He considers grass on these light lands as the most valuable crop, and indispensable to their improvement; and without the use of the roller it would be difficult to bring them into grass.

Mr Clark here read some extracts from the address of Mr Allen Putnam, at the Essex Agricultural Show last autumn. We need not soon to give this excellent address to our readers in full, and therefore omit the quotations.

Mr Clark proceeded to say that he thought too much stress was laid upon the benefit to be derived from hoeing corn. When there were no weeds, he preferred passing a harrow among the corn to hoeing, especially on account of the saving of time. He harrows his corn once in four days, alternately each way, if the weather admits of it. The growth of the corn after the hoeing is very rapid.

When the corn is killed, it required two or three days to recover itself from the injury of the hoe or plough. The admission of light and air is most important. Some persons doubt whether light has any agency in respect to the crop. After three or four days of cloudy weather, any one may observe that the tops of the forest trees become yellow. After a bright sun, the appearance will be changed. The effect of excluding light in bleaching the celery plant, every one knows. The stirring the earth around cabbage plants, a fact with which every farmer is familiar, quickens their growth in a remarkable manner; and this from breaking the crust which forms on the surface after rains or dews, and without any reference to the eradication of weeds. The opening, therefore, of the surface of the ground to the access of light and air, is of great importance. The surface becomes impervious to light and air, when it is not stirred, which checks the growth of the plant. This crust must be broken, and this may be done by the harrow more effectually than by the hoe, and at a tenth part of the expense. Weeds must not, of course, be suffered among growing crops, but the loosening of the surface is a matter upon which too much stress cannot be laid. Some persons advise at the first hoeing to take away the earth from the hill and supply fresh earth. He does not know the advantage of this.—

The hilling of corn is not approved by Mr Clark. In the account given of hilling, in Dr Hartwell's crop, he does not perceive any decisive evidence of its advantage. Corn throws out many lateral roots: these are always near the surface: here the roots find their principal nourishment. No advantage can come from burying these roots by hilling. The roots of the corn will cover the whole surface if suffered to extend themselves freely. No advantage can come to the roots, and the plant will suffer, but it will be done by the harrow more effectually than by the hoe, and at a tenth part of the expense. When the surface only is broken, corn advances without interruption. Much labor is expended uselessly in hilling corn. The only object of such labor should be to destroy weeds. The corn suffers much after such an operation, in endeavoring to accommodate itself to its new condition. He deems it a very bad practice to turn weeds under. Corn is in this way sometimes very much injured. A neighbor of his, Mr Henry Shepherd, of Northampton, with a view to determine the utility or evil, if any, of hilling corn, has made a series of experiments for several years, by hilling half an acre moderately in the middle of his field. The rest of the field, manured in the same manner, has been cultivated without hilling. The results show conclusively that the crop is diminished by hilling. The hilling of it corn hastens its ripening, but it is at the expense of the product. Cutting its roots like tapping the stalks, tends to ripen the crop prematurely; and in a proportional manner to diminish its productiveness. In a season of early frosts, the crop has been partially saved by thus forcing its maturity; but in favorable seasons, the ripe crop will be considerably lessened by such a process.

Mr Clark declined adding more at this time, as he would not be thought to desire to monopolize the time of the meeting. There was much more, however, that he would be glad to state. We hope he will not fail to avail himself of an early opportunity to continue his instructive remarks.

TO READERS AND CORRESPONDENTS.

The state of our columns does not admit at this time our giving the interesting remarks of Mr Mennan and Mr Carter, at the fifth agricultural meeting. We shall report them the next week.

We owe an apology, likewise, for failing this week to give at large the remarks of Hon. Isaac Hill. The matter is in reserve, and it is much too good and too well matured to be in danger of being injured by being kept.

We have received the reports of the Massachusetts Society on Grain and Vegetable Crops, which we shall give in the next Farmer. They came too late for this week's insertion.

We have the pleasure of laying before our readers a communication from Mr Meriam, on an important subject, which we know will be read with interest.

We refer to our friend W. B. at Mount Osceola, if he will pardon the vulgarism, "Go ahead!" The agricultural public are largely in his debt. The consciousness of doing good and giving pleasure, is a reward which his good moral development will teach him how to value.

H. C.

The Sixth Agricultural Meeting will be held at the state House on Thursday evening, 29th inst., at 7 o'clock. Subject of discussion—Indian Corn and the Small Grains.

MAGNIFICENT AGRICULTURAL TROPHIES.

The following is a list of the weight of hogs fatted on the farm of Elias Plimney, Esq., in Lexington, and sold at the stall of Mr George Munroe, corner of Fleet and Ann Streets. These are only a portion of those which are to be graduated at this noble Porcellan Seminary. The date of their degree is annexed.

What farmer's sty or what butcher's stall in New England, or in Old England, ever presented a finer exhibition? May the classes at Harvard do like credit to our keeping; or, as was pleasantly said by an Ex-venturer at the Brighton Cattle Show—"May their do them equal justice."

BRIGHTON MARKET.—MONDAY, Feb. 17, 1840.

Reported for the New England Farmer.

At Market 305 Beef Cattle, 10 Cows and Calves 325 Sheep.

Prices.—Beef Cattle—The prices obtained last week a like quality were hardly sustained, and we reduce quotations on the first quality. We quote First city, \$6 75. Second quality, \$6 25 a \$6 50. Third city, \$5 25 a \$5 75.

Cows and Calves—A few sales only were noticed and are of ordinary quality. \$28, \$50, and \$35.

Sheep—We quote lots at \$2 70, \$3 25, \$4 00, \$4 50, \$5 00.

Pigs—None at market.

Cattle—B. We intended to have noticed in our report last week, a yoke of beautiful cattle, fed by Mr Ichabod Stow, Lowell, Mass., weighing, when slaughtered over 3,000.

ROHAN POTATOES.

Five barrels of genuine Rohan Potatoes may be had on application to the subscriber. Price \$5 per barrel.

WILLIAM KENRICK.

Wentworth Hill, Newton, February 19.

FOR SALE.

Four and Saw 15 months old. Also 3 Sows 8 months. Full Blood Berkshire, from the stock of C. N. Beal. The sows are all with pig. Inquire of February 19. JOSEPH BRECK & CO.

THERMOMETRICAL.
Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded Northernly exposure, week ending February 16.

WEBSTER'S SEEDS.
The subscribers beg leave to state that they have received Mr Webster's Seeds; those who wish to experiment upon them and obtain a portion, had better call or send soon. They are as follows:

- Hopeston Winter Oats.
- Essex do.
- Dutch Poland Spring do.
- Keat Tartary do.
- Essex Winter Beans.
- Mumford's Garden, or Horse Beans.
- Yorkshire Prolific Beans.
- Suffolk Harard Tick do.
- Whittington Winter Wheat.
- Surrey Golden Drop do.
- Winter Tares, or Vetches.
- Spring Tares, or Vetches.
- Italian Rye Grass.
- Pacey Rye Grass.
- White Gate Farming Pomeranian do.
- Swedish do.
- Red Tankard do.
- Yellow Scotch do.
- White Tankard do.
- Purple Top Hybrid.
- Red Globe Mangel Wurtzel.
- White do.

We have also received some of the Early Hope Cabbage Seed, which was tried last year at New York and proved to be superior to any Early Cabbage hitherto known in the country.

We have now in New York, which will come to hand in a few days, some of the Chevalier Barley, which we shall be happy to offer to our customers.

It has been understood by some that the seeds were left with us for gratuitous distribution. We wish to correct this mistake as it is not the case. We were directed to dispose of them at a small advance, sufficient to pay for our trouble, storage, &c. JOSEPH BRECK & CO. Boston, Feb. 12, 1840.

SEEDS FOR HOT BEDS.

- Early London Cauliflower
 - Early Dutch do.
 - Early York Cabbage.
 - Early Hope do. (very superior.)
 - Early Broccoli, of sorts.
 - Snoo's Early Frame Cucumber.
 - Giant White Solid Celery.
 - Do Red do.
 - New Dwarf Red Solid do.
 - Do, White do.
 - Superior Double Curled Parsley.
- For sale by JOSEPH BRECK & CO. February 19.

THE FARMER'S COMPANION.

Or Essays on the Principle and Practice of American Husbandry with the Address prepared to be delivered before the Agricultural and Horticultural Societies of New Haven County, Connecticut, and an Appendix containing Tables and other matter useful to the Farmer. Second edition. By the late Hon. Jesse Buel, conductor of the Albany Cultivator. For sale at the New England Farmer Office. February 19. JOSEPH BRECK & CO.

GARDENER WANTED.

Wanted, a Gardener of steady habits, that understands raising vegetables and taking care of fruit trees. An American, with a small family, would be preferred. None need apply without good recommendations. February 19.

GARDEN MATS.

For sale at the New England Farmer, 100 dozen Garden Mats, of extra quality, for covering hot beds, &c. Feb. 12. JOSEPH BRECK & CO.

MISCELLANEOUS.

REWARD OF INDUSTRY.

AN ANECDOTE OF IVAN, OF RUSSIA.

The czar Ivan, who reigned over Russia about the middle of the sixteenth century, frequently went out disguised, in order to discover the opinion which the people entertained of the administration. One day, in a solitary walk, near Moscow, he entered a small village, and pretending to be overcome by fatigue, implored relief from several of the inhabitants. His dress was ragged; his appearance mean; and what ought to have excited the compassion of the villagers, and insured his reception, was productive of refusal. Full of indignation at such treatment, he was just going to leave the place, when he perceived another habitation to which he had not applied for assistance. It was the poorest cottage in the village. The Emperor hastened to this, and knocking at the door, a peasant opened it, and asked him what he wanted. "I am almost dying with fatigue and hunger," answered the czar; "can you give me a lodging for one night?" "Alas!" said the peasant, taking him by the hand, "you will have but poor fare here, you are come at a bad time. My wife is very ill, her cries will not let you sleep; but come in: you will at least be sheltered from the cold; and such as we have you shall be welcome to." The peasant then made the czar enter a little room, full of children. In a cradle were two infants sleeping very soundly; a little girl, three years old, was sleeping on a rug near the cradle; while her two sisters, the one five years old, the other seven, were on their knees, crying and praying to God for their mother, who was in a room adjoining, and whose piteous plaints and groans were distinctly heard. "Stay here," said the peasant to the emperor: "I will go and get you something for your supper." He went out, and soon returned with some black bread, eggs, and honey. "You see all I can give you," said the peasant, "partake of it with my children. I must go and assist my wife." "Your charity, your hospitality," said the czar, "must bring down blessings on your house. I am sure God will reward your goodness." "Pray to God, my good friend," replied the peasant: "pray to God Almighty that she may have a safe delivery from all her sufferings, that is all I wish for." "And is that all you wish for, to make you happy?" "Happy; judge for yourself; I have five children, a dear wife who loves me, a father and mother, both in health, and my labor is sufficient to support them all." "Do your father and mother live with you?" "Certainly; they are in the next room with my wife?" "But your cottage here is so very small."

The peasant then went to his wife, who in an hour after happily presented him with a son. Her husband, in a transport of joy, brought the child to the czar. "Look," said he, "see what a fine, hearty child he is!—may God preserve him as he has done my others!" The czar, sensibly affected by the scene, took the infant in his arms: "I know," said he, "from the physiognomy of this child, that he will arrive, I am certain, at a great preferment." The peasant smiled at his prediction, and at that instant the two eldest girls came with their grandmother, to take him back. The little ones followed her; and the peasant lying down upon his straw, invited the stranger to do the same. In a few moments the peasant was in a sound and peaceful

sleep; but the czar, sitting up, looked around and contemplated everything with an eye of tenderness and emotion—the sleeping children and the sleeping father. An undisturbed silence reigned in the cottage. "What a calm! what a delightful tranquility!" said the emperor; "avarice and ambition, suspicion and remorse, never enter here. How sweet is the sleep of innocence!" In such reflections, and on such a bed, did the mighty emperor of the Russians spend the night! The peasant awoke at the break of day, and his guest taking leave of him said, "I must return to Moscow, my friend—I am acquainted there with a very benevolent man, to whom I shall take care to mention your humane treatment to me. I can prevail on him to stand godfather to your child. Promise me that I may be present at the christening: I will be back in three hours at farthest." The peasant did not think much of this mighty promise, but in good nature of heart, he consented, however, to the stranger's request.

The czar immediately took his leave; the three hours were soon gone, and nobody appeared. The peasant, therefore, followed by his family, was preparing to carry his child to the church; but as he was leaving his cottage, he heard on a sudden the trampling of horses, and the rattling of many coaches. He looked out, and presently saw a multitude of horses, and a train of splendid carriages. He knew the imperial guards, and instantly called his family to see the emperor go by. They all ran out in a hurry, and stood before the door. The horsemen and carriages soon formed a circular line, and at last the state coach halted directly opposite the good peasant's door. Guards kept back the crowd which the hope of seeing their sovereign had collected together. The coach door was opened; the czar alighted, and advancing toward his host, thus addressed him: "I promised you a godfather; I am come to fulfil my promise; give me your child, and follow me to the church." The poor peasant stood like a statue; now looking at the emperor with the mingled emotions of astonishment and joy, now observing his magnificent robes, and the costly jewels with which they were adorned, and now turning to the crowd of nobles that surrounded him. In this profusion of pomp he could not discover the poor stranger who had lain all night with him on the straw. The emperor for some moments silently enjoyed his perplexity, and then addressed him thus: "Yesterday you performed the duties of humanity; today I have come to discharge the most delightful duty of a sovereign, recompensing virtue. I shall not remove you from a situation to which you do so much honor, and the innocence and tranquility which I envy, but I will bestow upon you such things as may be useful to you. You shall have numerous flocks, rich pastures, and a house to enable you to exercise the duties of hospitality with pleasure. Your new-born son shall be my ward, for you may remember," continued the emperor, smiling, "that I promised he would be fortunate." The good peasant could not speak, but with tears of grateful sensibility in his eyes, he ran instantly to fetch his child, brought him to the emperor, and laid him respectfully at his feet. This excellent sovereign was quite affected; he took the child in his arms, and carried him to church, and after the ceremony was over, unwilling to deprive him of his mother's nourishment, he took him to the cottage and ordered that he should be sent to him as soon as he should be weaned. The czar faithfully observed his engagement, caused the boy

to be educated in his palace; provided amply for his future settlement in life, and continued ever after to heap favors upon the virtuous peasant and his family.—*P. C. Journal.*

VEGETABLE CUTTER.

Willis's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and esculent roots fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public; they are aware that it has been long wanted and they offer a machine that cannot fail to give satisfaction upon a fair trial. It will cut with ease from one to two bushels in a minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at Agricultural Warehouse, 51 and 52 North Market Street, December 13. JOSEPH BRECK & CO.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that grot bones form the most powerful stimulant that can be applied to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and charge for cartage or carting.

Also, ground Oyster Shells.

Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse & Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

NAHUM WARD

FLOWER SEEDS—CHOICE VARIETIES.

JOSEPH BRECK & CO. have received a choice assortment of Flower Seeds from England and France, which, addition to what have been raised under their own inspection, embrace the finest collection to be found in the country, including all the new Annuals, Biennials, and Perennials worthy of cultivation; neatly done up in papers at 6 1/2, 12 1/2, and 25 cents each. For sale at 51 and 52 North Market Street. February 5.

SCIONS OF FRUIT TREES FOR SALE.

The collection of fruits cultivated at the Pomology Garden consists of more than 1400 varieties of the Apple, Pear, Plum, Cherry and Peach. Scions of all those which have been proved are offered to nurserymen and others. Gentlemen wishing to send collections of American fruits their friends in Europe can be furnished with most of the first rate quality. They are warranted true to their name and are in all cases cut from fruit bearing trees. Salem, January 28, 1840. ROBERT MANNING

A MAN WANTED.

To do the work on a small place, a few miles from city. He must understand the cultivation of vegetable fruits, &c., and the care of horse, cows, &c. A single man from 20 to 30 years of age, of steady and industrious habits may inquire at this office. J. B. I. January 15.

FOR SALE.

An excellent Farm, pleasantly situated about 20 miles from the city, containing about 100 acres. For full description, particulars, &c. inquire at this office.

Also, a situation wanted by a man with a small family carry on a farm. January 20. 4w

RHODE POTATOS.

For sale at the New England Agricultural Warehouse & Seed Store, No. 52 North Market Street, at 85 per barrel. October 16. JOSEPH BRECK & CO.

N. E. FARMER.

For the New England Farmer.

REPORT ON THE BEST CULTIVATED FARMS.

The Committee of the Trustees of the Massachusetts Agricultural Society, for awarding premiums on the best cultivated farms, have attended to that and report as follows:

The number of claimants is but four. The committee withhold an expression of their deep regret, that among the many enterprising and successful farmers of our commonwealth, so few should be disposed to put in their claims for the premiums offered by the Society.

The Society believed that they could in no way promote the interests of agriculture, than by creating a considerable portion of the funds, in former years had been expended at the cattle show at Brighton, in a way that they would operate as a stimulus on farmers to improve the condition and thereby increase the profits of their farms. And here it may be observed, while they have considered it advisable to bestow a large amount in premiums for the best cultivated farms, and for the most successful efforts in the culture of the various crops, they have also to be regarded the encouragement of farms, in the production and propagation of improved breeds of stock. This they have done by distributing a portion of their funds to the county societies, which had, in a great measure, absorbed the intention before their establishment had been that the State show at Brighton, to be appropriated, under the direction of committees of the State society, in premiums for the best

The results, as reported by the committees, and to that service, have fully satisfied the necessities of the expediency of that measure. And their efforts to bring about a competition among farmers for premiums on the best cultivated farms have not been attended with all the success which could wish, they nevertheless hope and believe will eventually tend to elicit much emulation, and to elevate the character of our rural community.

Among the few farms offered for inspection with a view of obtaining a premium, the committee are in finding most of them of a character highly meritorious, and deserving of public notice and commendation.

The system pursued by Robert Colt upon his farm at Pittsfield, with some few exceptions, we regard as highly judicious, and fully entitles him to the appellation of a skillful and enterprising farmer. His time and manner of ploughing, his plans for making compost, and his rotation of crops, are such as we apprehend all judicious farmers must approve.

The committee are aware that many good farmers would consider Mr Colt's plan of applying green manure, as a top-dressing, upon grass, to be bad economy, believing it better to mix

this manure with loam or peat mud during the summer, and to spread the compost upon the grass in the following spring. It is, however, the practice of many very successful farmers, to apply long manure to their grass lands in the manner pursued by Mr Colt. This top dressing of long manure when applied in the spring when the grass is starting, is the only time at which any top-dressing should be applied, is subjected to but trifling loss from evaporation, being soon shaded by the grass, and the nutritive parts which are disengaged, are carried down by rains. It is by the fermentation of long manure when unmix'd with other substances, to imbibe the gases, or what is called ammonia, more than by drying, that the nutritive properties of manure are lost. But when swamp or peat mud or loam can be had to mix with unfermented manure, the committee are of opinion that the farmer will find it more economical to make a compost for his top-dressing. The mud or vegetable mould will imbibe all the ammonia that is thrown off by fermentation, and at the same time add much to the value of the heap. By mixing lime with the mass the compost will be greatly benefited, as it will hasten the disengagement of ammonia, and at the same time aid in correcting the acidity in the peat mud.

Mr Colt turns over his green sward in the spring, which we think preferable to fall ploughing. It is well known that any vegetable or animal substance when buried in the spring or summer, will decompose more rapidly and thoroughly, and of course the soil made lighter, than when buried in the fall or winter. There is another very great advantage derived from spring ploughing. The green herbage which is turned under will furnish an ample supply of food for the worms, which usually abound in green sward, and will therefore seldom seize upon the growing crop. The correctness of this theory has been well established by the experience of some intelligent farmers made known since the publication of the committee's last annual report, in which this time of ploughing and for the same reason, was recommended.

We take the liberty of suggesting for the consideration of Mr Colt, whether it would not be an improvement on his plan of rotation of crops, to plant his sward lands the first season after turning over, with corn, roots, or other hoed crops, rather than sowing with the smaller grains; and instead of corn or roots the second year, to sow the smaller grains and stock with grass seed, without disturbing the inverted sod. The surface the second year, may be made sufficiently smooth with the cultivator and harrow, for the reception of the grain and grass seed, and it is unnecessary to assure any farmer who will take the pains to examine for himself, that the inverted sod which is kept down, is much lighter and in better condition for allowing the roots of the grain or grass to penetrate, than it can be put into by all the ploughing that can be given to it. By this process, the poorer part of the soil which has been turned up, is kept at the surface and enriched by exposure to the action of the atmosphere, and by cultivation, the soil thereby deepened and improved and put in better condition for a second ro-

rotation. Some of the committee have tried Mr Colt's plan of sowing grain upon the inverted sward the first season after turning over, and have found the crop to be materially injured by the grass growing up from between the furrow slices. Where a crop of corn or roots is planted the first season, the grass is kept down by the hoe, and the field left clean and in fine condition for wheat, rye or oats, and laying to grass the second season.

The location of Mr Colt's farm is favorable and the soil naturally good, and withal exhibits strong proofs of judicious and successful cultivation. Mr Colt has also done much by way of introducing and propagating the improved breeds of cattle and swine. The committee are therefore unanimously of opinion that he is entitled to, and they accordingly award him the first premium of \$200.

The farm of Joshua R. Lawton, of Great Barrington, is well managed. The committee do not approve of all his plans, particularly his mode of ploughing green sward, and his habit of stacking and feeding out his hay upon his fields. His rotation of crops we consider judicious, and exactly corresponds with the views of the committee upon that subject. His farming operations generally, are conducted with a good degree of skill and success, and with a very commendable zeal for improvement. The committee award him the third premium of \$150.

The farm of Increase S. Wheeler, of Framingham, appears to be well and profitably managed by Mr Vose, a very faithful agent. He manages liberally, and considering the nature and quality of his soil, he gets large crops.

In heavy manuring, judiciously applied, consists in a great measure, the secret of profitable cultivation, and Mr Wheeler has no doubt satisfied himself of the fact, that one acre of land dressed with forty loads of manure will yield a greater net profit to the owner, than two acres manured with only twenty loads each. This shallow ploughing is decidedly objectionable, and should be denounced by every farmer who calculates to thrive by the plough. This deteriorating practice, so long pursued by our ancestors, has reduced many of our New England farms to hungry knolls or barren wastes. Deep ploughing and liberal manuring are the only sure and expeditious means of restoring them. If we would effect substantial and permanent improvement of our soils, and desire to reap abundant harvests, we must begin by deep ploughing. The reasons for this are too obvious, and the principle too well settled to admit of a doubt.

Mr Wheeler's buildings are well constructed, and his plans for making manure are ample and well contrived, having a cellar under the whole of his barn, well adapted to this purpose. He has been fortunate in the selection of his breed of swine. It would have been gratifying to the committee to have been informed of the age of his hogs, the method and expense of fattening. The average weight of 5 of the 11 hogs slaughtered on his farm, was over 500 lbs.; and the average weight of the whole over 443 lbs.; much beyond the usual average weight of hogs. When the fact is so ap-

parent and so well established that there is a certain profit in fattening some breeds of swine, and as well established that there is a certain loss on others, it is matter of surprise that farmers generally pay so little attention to the selection of their breed.

While upon this subject, the committee are reminded that they can render an important service to farmers, who are desirous of obtaining information on this interesting branch of rural economy, by recommending to their perusal a work entitled the "American Swine Breeder," written by Henry W. Ellsworth, Esq., and recently published in this city by Weeks, Jordan & Co. The book is well written, and is highly creditable to the respectable author, whose industry and research has enabled him to communicate much sound practical information on this important branch of agriculture. It is well entitled to the notice, and should be in the hands of every farmer.

With the exception of shoal ploughing, we think well of Mr Wheeler's skill as a farmer, and accordingly award him the fourth premium of \$75.

The agricultural operations of Mr Jacobs, of West Scituate, appear to be strictly confined to the old system of husbandry. His farm, however, exhibits an appearance of great neatness, and speaks well of the industry and thrift of its owner, who has contrived to support a numerous family, and to accumulate considerable wealth from the proceeds of his farm alone. The committee recommend that a gratuity of fifty dollars be given to Mr Jacobs.

All which is respectfully submitted by your committee.

WM. PRESCOTT,
P. C. BROOKS,
E. PHINNEY,
JNO. C. GRAY,
HENRY CODMAN.

REPORT ON VEGETABLE AND GRAIN CROPS.

The committee of the Trustees of the Massachusetts Agricultural Society "on Grain Crops," report:—That two claims only were presented, which the committee thought deserving of premiums, viz.

1. To Seneca Adams, of Newburyport, for his crop of onions, being 476 1-2 bushels on an acre, \$20.

On the same acre were raised, beside the onions, 65 bushels of potatoes, some corn and beets.

2. To Peleg S. Gardner, of Somerset, Bristol county, for his extraordinary crop of winter rye, being 84 bushels on two acres, weighing 56 lbs. the bushel, lacking six ounces—\$20.

One other claim was made by Tristram and David Little, not verified by the certificate of any disinterested laborer, as required, and exhibiting no product which, in the opinion of the committee, is deserving of a premium. They are sorry thus to decide on a claim from those whose former applications have been so respectable.

The committee recommend, as usual, that the statements of the claimants to whom premiums have been awarded, be published as part of this report.

Per order,

P. C. BROOKS.

February 7, 1840.

To the Committee of the Massachusetts Agricultural Society on Agricultural Products.

The subscriber presents for premium the follow-

ing crop of rye—the product of two acres of land, cultivated by him on his farm in Somerset, Bristol county.

The land in question, is situated near the margin of Lee's river, in the aforesaid town, and is rather a dry, gravelly soil, well adapted to the growth of rye, when judiciously managed. The last year the crop was potatoes, and about eighty barrels of Menhaden fish used as a manure. The crop of potatoes were quite good for the season. The land for sowing the rye was ploughed the latter part of September. The rye was then sown: nearly three bushels of seed was used: no manure was used the present season. The crop of rye promised well, and proved to be good: the harvest was completed in July, and the threshing was done the latter part of August and beginning of September, and the whole product found to be eightyfour bushels, of nearly fiftysix pounds, the loss in getting the crop being more than doubly sufficient to make up for the loss of about six ounces to the bushel in weight short of fiftysix pounds.

The value of the crop is estimated as follows:

84 bushels rye at \$1,	\$84 00
3 tons straw at \$5,	15 00
	\$99 00

The expenses of the crop are thus estimated:

For ploughing land and getting in rye,	\$5 00
3 bushels rye for seed,	3 00
Reaping, binding and stacking,	8 00
Threshing, cleaning, &c.	10 00
	\$26 00

Somerset, Nov. 21, 1839.

P. S.—The land before named is the same lot presented for the Society's notice in 1837, but being too late, obtained only a gratuity of ten dollars.

P. S. G.

I certify that I assisted in the cultivation of the crop of rye as set forth in the foregoing statement, and that said statement is true, according to my best knowledge and belief.

ISAAC J. SIMMONS.

I certify that I have surveyed the lot of land referred to in the foregoing statement, and that said lot contains two acres and no more.

DAVID GRAY.

COMMONWEALTH OF MASSACHUSETTS.

Bristol, ss. Nov. 21, 1839. Then Peleg S. Gardner, Isaac S. Simmons and David Gray, made oath severally to the truth of the foregoing statements by them subscribed—before me,

JOHN MASON, Justice Peace.

To the Trustees of the Massachusetts Agricultural Society:

GENTLEMEN—The following is a statement of a crop of onions raised by the subscriber the past season, which is offered for your premium.

In the summer of 1838, the land was planted with potatoes and onions, and manured with three cords of stable dung. The crop was not large, as near as I can recollect. About the first of May, 1839, drawn on 3 1-4 cords of manure, which was ploughed in: the ground was harrowed smooth: three

pounds of seed was sowed with a machine in row ten days' labor in weeding the same: four do. harvesting; and there were four hundred and sixty and a half bushels of onions and sixty do. of potatoes, eight do. of corn, and nine barrels of beets.

The expense of cultivation was as follows:

3 1-4 cords of manure,	\$13
Ploughing and harrowing,	2
Seed,	4
Sowing,	1
Weeding,	1
Harvesting,	4
	\$35

Respectfully, yours,

SENECA ADAMS

Newbury, Nov. 25, 1839.

I the subscriber, hereby certify that Daniel Plumer, of Newbury, personally appeared before me, and was sworn to survey the above described land according to the best of his abilities.

SAM'L NEWMAN,
Justice of the Peace

Newbury, Nov. 23, 1839.

I hereby certify that I surveyed the above which contains one acre.

Nov. 23d, 1839. DANIEL PLUMER

This may certify that I assisted in harvesting the above crop, and the within statement is correct.

SAMUEL PLUMER

We with pleasure give place to the subject of communication, which was read at the Fifth Annual meeting. The sample of corn sent you the same time, is remarkable for its size; should any of our friends wish for some of the seed, Dr Hartwell would be happy to supply them. I wish the Dr would be kind enough when a convenient opportunity presents, to send us a trace half a dozen ears, as we are desirous of seeing corn on the cob.

H. C.

For the New England Farmer.

GROWING INDIAN CORN.

As this is one of the principal staple products of the agriculturalist of New England, I believe the result of my crop of corn, together with the method adopted for its production, will interest many of your readers.

The piece of land upon which my corn was raised, has been accurately surveyed by Mr L. Anderson, and was found to contain one acre, one rod and four rods. (See certificate.) It may be proper to state that this survey includes only the land which the growth of corn occupied, and was measured from wall to wall, but the lines were upon the outside rows of corn.

The corn in the ear which grew upon this has been accurately measured in the presence of the Hon. Linus Child and Moses Plimpton, Esq. whose certificates are subjoined. The quantity thus measured amounted to two hundred and eighty eight bushels. I have since caused one and a half bushel of these ears of corn to be shelled, agree to the above measure, and find that a bushel and half of ears yields seven half pecks of corn, which

ld make in the whole 150 1-2 bushels of shelled corn. But a deduction should be made for the loss of the corn, it not being yet sufficiently to be called marketable, how much it will be estimated. I am not sufficiently experienced to form a correct estimate.

The soil which I cultivate is what geologists call *loam*; it contains a small trace of clay, and a small amount of iron; no lime can be detected; it has more than the usual attraction for moisture, and in natural state, was called by farmers cold moist—the produce of which ten years ago, was not worth twenty cents to the acre: it was subdued by being brought into mowing by myself, about eight years ago, in which condition it has remained—a fine loam, without manure or cultivation, until a year ago, when it was simply ploughed.—At the first week in May it was harrowed, and heavy loads of long or green horse manure were spread over it: it was then ploughed as deep as it could be conveniently done; then harrowed again with a horse harrow, and seventeen loads to the acre of fine fermented manure which had lain in a pile during the winter, spread over it and ploughed lightly with a horse. The land was then furrowed the usual way only, with a space of three feet and six inches between the furrows: seven loads of manure to the acre was put in the hill, at about the distance of two and a half feet. The corn was sown upon this small quantity of manure to the depth of an inch on the tenth of May—five or six kernels to the

hill. The corn was hoed (ploughed but one way) three times in the old fashioned way, by hilling up, on the tenth and twentieth of June and first week in

July. Its extraordinary production is to be accounted for by the manner of cultivation and partly by the kind of corn that was planted. In the first place it is necessary from the shortness of our season to select a kind of corn the most prolific and which will ripen in the shortest space of time.—The soil, the land and manure should be adapted to the immediate wants of this tender plant from its early germination. It is well known to agriculturalists, that the best and only proper nutriment for growing plants is *geine*, or decomposed organic matter. Now it will be seen that this method of growing manure (above mentioned,) is well calculated for these purposes. The small quantity of manure that was put in the hill, contained the corn in a soluble state—ready elaborated for the wants of the tender infant plant. The second kind of decomposed manure was calculated to be in a similar manner, after the corn roots had expanded to their farthest extent and exhausted the soluble *geine* in the hill: the green or long manure, which was first deeply ploughed in, would be decomposed, and the *geine* rendered soluble and fit for assimilation by the corn at the time arising and filling out.

At the time of hoeing, I prefer the plough to the harrow, for this reason—that it elevates the hill: I observed that a hill of corn on my acre that had been raised above the general average height, yields the best crop; while one below the average, yields small corn.

At the third hoeing the plough sinks into the soil and brings the *geine* within reach of the roots of the corn—while at the same time the subsoil completely covers the soil surface, preventing the same from evaporating during the hot weeks in July and Au-

gust. Or should a superabundance of rain fall, the gutters are cut one way only by the plough to carry off the water.

The kind of corn which I planted I consider to be the best adapted to our northern latitude, of any that can be found. It contains eight rows of kernels, is of a beautiful golden yellow color, producing occasionally three, and very frequently two ears on a stalk: the cob is comparatively small, as will be seen by the average of shelled corn to the bushel of ears: the kernel is deep and large—quite heavy—fifty of the largest weighing an ounce. I have no particular name for this corn.

SAMUEL HARTWELL.

I hereby certify that I surveyed the ground for Dr Hartwell above referred to, and found it to contain one acre, one fourth and four rods.

LUCIUS H. AMMIDOWN,

Surrey.

We hereby certify, that we were present at the measuring of Dr S. Hartwell's corn, above referred to, and found it to be two hundred and fiftyeight bushels of ears.

LINUS CHILD,
MOSES PLIMPTON.

Southbridge, Oct. 17, 1839.

For the N. E. Farmer.

A KNOWLEDGE OF BOTANY IMPORTANT TO THE FARMER.

Botany, or the science of plants, is one of very great importance to the world, inasmuch as from its subjects we derive many of the most important remedies for our sicknesses, as well as the essential and luxurious articles of our diet in time of health. So greatly important are its subjects in supplying the physical wants of man, that if they were extinguished from the earth, then indeed it would become a desert, unfit for the abode of rational beings, whose existence here must also cease with death of vegetable nature.

The importance of a knowledge of this science to a farmer, is so clear that it might seem an idle waste of words to employ them in attesting the sobriety of the fact. He lives surrounded by the vegetable kingdom. The employment of *his life* is to cause the herb and the tender plant to shoot forth with more luxuriance, and to improve in quality under his nursing care. All nature contributes of its energies to aid him in his grand designs. The storm and the sunshine, day and night, times and seasons, are powerful auxiliaries in accomplishing his will. Nor are the results of his labors, his failures or successes, fraught with consequences to him alone. "The king himself is served of the fruit of the field." This wondering eyes and fainting stomachs of every other class in community, from the king on his throne to the culprit in his cell, demand of him the life-continuing necessities and comforts of their existence. To them, then, he is responsible for the care with which he sows and the attention whereby he reaps.

It is not our object in this short communication, to call the attention of young farmers to the analysis of flowers and by that to a classification of plants. This, however important it may be in the economy of farming, would be deemed an act of ultraism quite unparadonable. Still, however, its advantages must be evident, as the anecdote of the immortal

Linnaeus will fully demonstrate. It will be recollected by many, that in one of his botanical excursions he visited a country where the cattle were all dying off as by a pestilence, greatly to the dismay and pecuniary damage of the inhabitants. By his research, he discovered growing in their fields a plant, which from its peculiar features, he pronounced the cause of the sad calamity. His discovery was communicated to the inhabitants, the weed destroyed, and the evils which it had occasioned were stayed. How far such applications of this science might produce salutary effects in this, and indeed all countries, we know not. There are probably many plants that we scarcely notice, which in their present localities, are exercising more pernicious effects than we usually imagine; and were their qualities fully known, we should probably be wondrous to ourselves that we allowed their existence, while their extirpation might destroy causes which are actually impeding our progress.

The connexion between vegetable physiology and practical agriculture is obvious, from the fact that all plants are living things, having periods of germination, growth, maturity and decay, and that to carry them through such an existence, they are provided with organs adapted to the various purposes which their existence requires—such as nutrition, exhalation, &c.; that their growth like that of animals, consists of an extension of their parts, which in different individuals varies in proportion with the circumstances attending it, and with the species and variety to which they belong.

Plants, unlike animals, are destitute of the powers of locomotion—consequently, the materials which continue their existence and enter into their composition and growth, must all be found in and around the little territory they occupy. Consequently, a knowledge of their nature and habits is of the greatest consequence to the cultivator, for without it he cannot adapt them to localities favorable to their perfect development; while by an acquaintance with these, he may, as has been done with many of our most valuable vegetables, cultivate them in a perfection far beyond what the workings of nature ever accomplished, even under the most favorable circumstances. Thus science aids him continually, if he will invoke her aid, in bringing new and undreamed of qualities to light. But if ignorance of the subjects of his care and solicitude, spreads its black cloud over his operations—his chances of success are small—not one, against ten of failure. Plants have the power of extracting from the atmosphere and the earth, such qualities as are best adapted to their growth; or rather they, after having partaken of the aliment which nature provides them, have organs for throwing off such substances as are foreign to their composition.—Hence we see that they will not often for two generations flourish to advantage on the same soils, and that those which are most tenacious of the parental inheritance, will eventually extract all those qualities, unless they are renewed, which are peculiar to themselves, and become extinct. While the earth is thus exhausting itself in the support of one kind of plant, it may be accumulating materials for the advancement of another; and from this supposition leads us to adopt a system of rotation of crops, a system which we find pervading the operations of nature, from her noblest forests of pines and oaks, to the more humble groves of ferns and lichens.—How, in the common pursuits of agriculture, shall we determine what kind of plants are best calculated to succeed such as have recently matured on

the soil? *Observation* to be sure may determine it, and life may hasten to its wane before we arrive at facts; and then, as *book farming* is denounced as a sort of unholy innovation, we must not record the results for the benefit of our successors. We may by a sort of instinct hit upon the right subject to transfer to the soil, but we are very likely to select something ungenial to its circumstances. But if *science* holds its lamp, whose oil is like that of the widow's cruise, unfailling, and the more we use the more remains, around our path, we can determine at once wherein the secret of our strength lies, and apply accordingly.

Plants, like men and animals, are liable to diseases and premature decay: and in the vegetable as in the animal kingdom, preventives when they may be had, are much better than cures. Disease is the result of various causes. It may result from a plant's being located in a soil ill adapted to supply its emergencies, while another of different family would flourish well:—in such cases the disorder may become hereditary, until at length the article becomes valueless; or it may by timely care be cured. The atmosphere of different localities may essentially affect vegetables, such as being too hot or too cold, too wet or too dry. These are evils which are to be avoided; but how on introducing a new plant or in pushing our experiments with the old, are we to dodge them? Just as the physician tells an individual what climates and exposures he must avoid and what habits he must adhere to, as he values health and life, by a knowledge of its systems, habits and predispositions.

Yours, truly, W. B.

Mount Osceola, Feb. 4, 1840.

For the N. E. Farmer.

NORFOLK ISLAND PINE.

A beautiful plant of this majestic and lofty tree, is in the possession of the Hon. John Lowell, and has been reared by him in his green house at Roxbury. Whoever has visited the annual festival of flowers and fruits of the Massachusetts Horticultural Society, for the two past years, must recollect its elegant contour and vivid foliage. Its age we have reasons to suppose, is towards four years from the seed, and its height something more than three feet. Several seedlings were brought from the island, which gives a specific name to the tree; and if our conjectures are correct, of this lot, (the only one so imported to this neighborhood) is the fine individual above mentioned. Others of the same are growing in Salem and elsewhere, but none so fine as that in possession of Mr Lowell.

The Norfolk Island Pine belongs to a small group of forest trees, remarkable for their great height and peculiar proportions. Growing at a considerable altitude on the mountainous regions of its native habitat, it was reasonable to suppose that it might be gradually acclimated to some portion of our own latitudes. Attempts to cultivate it in the open air in Great Britain have failed. Curious however as it may seem, yet it is a well received fact among English geologists, that a plant very nearly identical with the Norfolk Island Pine, once grew in Britain, as proved by the frequent discovery of petrifications or vegetable remains in the lias of Dorsetshire, answering to this now foreign species.

The appearance of the Norfolk Island Pine, (scientifically called *Arcaucaria excelsa*), in its young

and mature stages of growth, are so distinct as hardly to be recognized as belonging to the same individual species of plant. The present condition of Mr Lowell's specimen renders it an attractive object in the collection of the green house. Its stem is covered with those scale-like leaves which we see in the fir balsam, while its axillary branches are entirely clothed with small, semitar-shaped foliage, scarcely imbricated, and bifarious. Sometimes this bifarious or parallel-rows character is inconstant, as we once saw in another specimen, where from some accident, a single row was present on the branch. As the tree advances in height, for this abundance of foliage is substituted long, pendent branches, towards the extremities of which only, clusters of leaves are to be seen. Rising to the elevated growth of 22½ feet, as in some instances, and being even 30 feet in circumference, it would be presumable that its timber must be of value. Its heaviness, however, renders it unfit for spars, and from a liability to unsoundness, is only used in in-door carpentry work.

Another and more curious species we have seen in this vicinity under cultivation—the *Arcaucaria imbricata*, which grows spontaneously on the mountains of South America, between 36° and 39° S. latitude. Its contour is much less graceful than *A. excelsa*, while its foliage is most singular, being of broad, lance-like, rigid and sharp-pointed dark green leaves, and not a little reminding one of some kind of Ruscus or butcher's broom. We have seen a plant of this kind in the collection of Col. M. P. Wilder.

A third species is *J. Brasiliensis*, growing in the southern provinces of Brazil, and much more impatient of cold. It resembles the last, but its leaves are longer, weaker and less densely and compactly imbricate.

Forest trees of the magnitude and superb proportion of these sorts of pines, are worthy the attention of the curious culturist. The second kind above mentioned, has been reared in the open air near London, and in a country like ours, embracing all temperatures, the intelligence and enterprise of its widely spread population should institute such series of experiments in the branches of arboriculture, as would render eminent service hereafter to the value and fertility of its soils.

BENDROPHILUS.

For the N. E. Farmer.

HINTS ON HANDLING BARS.

Since I commenced farming, I have hired many men, and never one that knew how to take out a pair of bars and put them up again in a proper manner. Farmers' bars are commonly made of split posts and split rails, and it sometimes happens that the posts or some of the rails, are a little winding, or some of the post holes are of a little different size from the others, so that a rail will go well in one place and not at all in another; that is, if they have been properly fitted, so that they will take out and put up well, if always put in the same place, where they were fitted to go, which is always easy, by observing the following method.

When a man takes hold of a bar rail to take it out, he always puts one hand on the under side of it: he should take the upper rail first, and lay it far enough off to make room for all the others; and lay it with the under side next to him, and so of all the others; it being perfectly natural so to lay

them. For putting up, take the rail next to the first, which will be the under one, and put the next to him down, and so of all the others. In this way the rails are always in their place. If hired men, until they are otherwise taught, take the rails out and throw them off, crossed and mixed up; and if it is a rail fence that adjoins a post, perhaps the top rail is broken; or if a stub wall, some of the top stones are thrown off; but no mischief is done, when they come to put them up again, they *no go*—then the post is racked about, and perhaps broken, and if no damage done, there is twice the time spent that would be necessary to do it in a proper manner.

It may be said, this is all a small concern may be so in the opinion of some; but let any man carry on a farm for fifty years and try to keep his bars as well as other things in order, and he will find as much mischief and loss of time as I have, by one small thing, and he will think it is worth tending to. Most hired men and some masters when they are passing with a team from a past where there are cattle, find it quite too much to put the bars up sufficiently to stop cattle, only a single rail, and that higher at one end than at the other, so that if the cattle come, they can get over or under, as suits their convenience, and they certainly will one or the other; and in this way the cattle on a farm will soon be made rogues. No calculating kind of man will say, "sure bind, find," and will have all his bars left so that they are known to be safe. A FARMER.

MANUFACTURE OF SILK.

That silk can be raised with perfect ease in our country—that our climate from north to south admirably adapted to the constitution and health of the worm, far better than that of Europe, and to the growth of the mulberry tree in its different varieties, has been satisfactorily proved by thousand experiments. While in Europe, owing to the mildness of their climate, nearly one half of the worms usually die from disease, and they are obliged to have their cocoons nicely reared in their temperature by the thermometer, here, owing to the dryness and warmth of our atmosphere with proper care, scarce a worm dies from disease and a building of the cheapest construction—out-house, shed or barn—answers perfectly for a cocoonery. That the silk made in this country is of the very best quality, for fineness, lustre and strength, equal to any in the world, has been decided by competent judges. Specimens of silk have been sent to European manufacturers, pronounced by them to be superior. There is no mystery or difficulty in raising the worm than in raising chickens. Persons have succeeded perfectly well, even to the reeling and spinning the silk into beautiful sewing silk, who never raised a silkworm or a cocoon before. If, then, a dance of the raw material, of the best quality be produced without any difficulty, what should hinder us from becoming a silk growing country, from manufacturing it, not only in sewing but into all the variety of silk stuffs used by people; and thus save the millions which are annually drained from us, to pay foreigners for raw and manufacturing our silk? We prophecy that in ten years we shall raise, if not manufacture our silk, and that in fifteen years, raw silk will form an important article for foreign exportation, as now our cotton.—*Albany Cultivator*.

From Low's Practical Agriculture.

THE TARE.

The Tare, *Vicia sativa*, is one of the most esteemed of the leguminous forage plants of this country (England). It is an annual plant, indigenous, and hardy. There are several varieties of it, one of which is distinguished by producing yellow seeds.

The tare, by being sown in autumn or in spring, acquires habits so different, that many have supposed the spring and winter tares, as they are called, to be different species. They are, however, the same species, and do not even constitute botanical varieties; but, from the different habits of ripening which they acquire, they should be always sown at periods to which they are respectively suited; thus, the winter tares should be sown in autumn, the spring tares in spring; for experiments have shown, that the spring tares sown in autumn frequently perish in the first frosts, while the winter tares will continue uninjured. This requires the more attention, as the seeds of the two are so similar that no means of discrimination exist.

When tares are cultivated for green food at a certain season, they are to be sown in spring; and in order to procure a succession of cuttings during the months of summer and autumn, portions of the land should be sown at intervals from the middle of March to the end of May.

When tares are to be sown in autumn, for early use in the ensuing season, the land frequently receives only one ploughing, after which the seeds are sown in the usual manner, and harrowed. A second further tillage, however, would be beneficial, and is thoroughly to prepare the ground.

When tares are sown in spring, the land should receive a ploughing before winter, as in the case of peas and beans. It should be cross-ploughed in spring, and well harrowed, and receive a second ploughing, if possible; for it is always well to prepare the surface carefully for the seeds of the plant. After they are sown, the land should be rolled, to facilitate the subsequent action of the ho. If manure had been required for the crop, it could have been applied in the previous autumn. Tares should always be sown on land which is in good condition and clean. It is a great error to sow tares on land which is not in this state. The same are considered in many places as a kind of crop; hence they are left to struggle with weeds, and made important advantages attending their cultivation are lost. The management of the tare in England is much superior to that pursued in other countries.

The quantity of seeds sown may be from 3 to 4 bushels to the acre. When the crop is sown for green food alone, a smaller quantity will suffice, as 2 bushels to the acre.

It is common to mix a portion of some of the cereals with the tare, the effect of which is to increase the quantity of fodder; the stems of the cereals rising above the foliage of the tares, and growing without interrupting each other. For winter tares rye is best suited, for spring tares oats or barley.

Tares, when used as green forage, are cut after the seeds are formed, but long before the seeds become ripe. Tares, therefore, being in the class of crops not allowed to mature their seeds, are not extending to the soil. On the contrary, with rela-

tion to the farm, they are to be considered as restorative crops, from the quantity of manure which the consumption of them affords. They are exceedingly nutritious, and supply a larger quantity of food for a limited period, than almost any other forage crop.

The usual mode of sowing tares is broadcast, though they are better sown in rows, like the pea and the bean. This, indeed, is by no means so essential to the success of the crop as in the case of the bean and pea, for the produce of the tare is chiefly the stem and leaves, and the pods and seeds are of little comparative importance; the admission of air, therefore, for the swelling of pods and seeds is not necessary. The plants, too, cover the intervals of the rows quickly, and so do not admit of much time and opportunity for tillage during their growth.

Tares are chiefly cultivated for green forage; but they may be also cultivated partially for their seeds. In this case, the mode of culture is the same as that of the pea. The land should not be too rich, so as to cause them to run to straw instead of producing pods; and it is a good practice to mix a small quantity of beans with them, to support and keep them from trailing on the ground.—The beans, from their difference of size, are easily separated by riddles from the tares. In the practice of the farm it is common to cultivate tares for green forage, and merely to reserve that part of the crop for seeds which is not used in this manner. They are then reaped, stacked, and dressed, like peas.

When the tare is cut very early, it may rise again and produce a second crop; and even a third cutting is sometimes obtained. In the northern parts of the island, the farmers scarce ever attempt to produce more than one crop in the season.

Tares are sometimes consumed by peaning sheep upon them; but the better practice is to feed the sheep from racks. When the larger animals are fed on this food, it should always be supplied to them from racks in houses or yards.

All the animals of the farm are fond of this legume, and all thrive upon it in an eminent degree. Hogs may be fattened entirely upon it. It is suited to milk cows, causing them to give more butter than any other species of food, and it is employed extensively in the feeding of horses. All the English agriculturists are impressed with a high opinion of the value of tares. They are not only casually employed, as in Scotland, to fill up the intervals between the cuttings of clovers, but they are often the principal source of feeding from the month of May to November.

There are several species of vicia, with broad leaves, resembling those of beans, cultivated in Germany for the same purposes as the tare:

1. *Vicia carthagenensis*—Narrow-podded Vetch.
2. *Vicia pterygosperma*—Broad-podded Vetch.
3. *Vicia serratifolia*—Saw-leaved Vetch.

But none of these species is equal in productiveness to the common tare.

Another of the genus vicia is *Vicia pseudo-cracca*, Annual Tufted Vetch. This species is of very luxuriant growth, but flowers at a late season. It is as yet untried in the agriculture of this country. It might, perhaps, supply a desideratum, namely, the affording of a large quantity of green forage after the pastures have begun to decay in autumn, and before the turnips and similar plants are ready for use.

Vicia biennis, Biennial Vetch, is a native of Si-

beria. This species is of luxuriant growth, and comes early in spring. It was cultivated by Miller so long ago as 1759, and recommended by him as a plant of great promise; but no experiments upon it on the large scale are recorded. Its stems have a certain degree of hardness, and its leaves a somewhat insipid taste.

Vicia sylvatica, Wood Vetch, is perennial. It grows in woods with a stem from 3 to 5 feet high, climbing by its tendrils, and bearing beautiful little flowers streaked with bluish veins. The wood vetch, as its name denotes is truly the inhabitant of woods, and, when removed to exposed situations, its size and productiveness diminish. For this reason, perhaps, it is not adapted to cultivation.

Vicia cracca, Tufted Vetch, grows in hedges and bushy places, climbing also by tendrils, and bearing numerous purple flowers. It is, like the last, perennial, but is more productive when removed from its natural habitat. It is, however, late in growing, and appears to be much inferior in usefulness to the clovers. It grows on soils of low fertility.

Vicia sepium, Bush Vetch, is a plant growing also in hedges and bushy places. It is perennial, flowers early, and yields a good weight of produce. Although its natural habitat is bushy and shady places, it grows in cultivated fields, and has a somewhat wide range of soils. From these characters, and the trials that have been made, there is reason to infer that the bush vetch would be a beneficial addition to the cultivated herbage plants of this country. There is great difficulty in procuring its seeds in its wild state, from its dispersing them as soon as ripe; a character, however, which would probably be changed by cultivation, as happens in the case of other wild plants.

Of the important genus *Vicia*, about 100 species have been enumerated by botanists, and many of them seem to be highly deserving of experiment for their economical uses.

[Continued.]

ROHAN POTATOES.

Mr BARCK.—Having grown the Rohan potatoes for the two years past, I would suggest, from my observation, that they should be planted early, on rich, moist land, with not more than two eyes to a hill. On dry land I should fear the bone manure. In fact I have not succeeded with bone, with any potatoes or corn. My yield in the garden without forcing, and with barnyard manure, has been about 136 per cent.; in a poor field, where the crop was overtaken by the frost, with the vines rank and green, and of course not at maturity, was 50 per cent. But in any case I have no doubt they will come into general culture, and when we have been fully advised of their habits, they will prove themselves a great favorite of the farmer. P.

Avarice.—Never has the avaricious man enough and never is he happy. He has no relish for the enjoyments of life, and deprives himself of its necessities to increase his riches. He fancies himself indigent, and trembles with the apprehension that he will yet have to beg his bread. By degrees he withers away, without having conferred a single benefit upon his species, and the fruits of his selfishness are left to his heirs, who do not even respect his memory.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, FEBRUARY 26, 1840.

A CARD.

The Commissioner of Agricultural Survey acknowledges the receipt of a fine sample of Parker corn, from Abram Washburn, 2d, Esq., of Bridgewater, whose farming has been repeatedly and deservedly honored by the premiums of the Plymouth County Agricultural Society. Feb. 23d.

SEVENTH AGRICULTURAL MEETING.

The Representatives' Hall being engaged for another purpose on Thursday evening, the Seventh Agricultural meeting will be held on Friday evening next, 25th inst. at 7 o'clock. Subject for discussion—The Small Grains. Gen. H. A. S. Dearborn, by invitation of the Committee of Arrangements, is expected to address the meeting.

SILK CONVENTION.

The Ninth Agricultural Meeting to be held at the State House in Boston, on the second Thursday evening in March, will be devoted to the discussion of the Silk Culture.

The attendance of gentlemen in any part of the country interested in this subject, is respectfully requested. The meeting will be continued by adjournment as long as may be judged expedient.

Publishers and editors interested in this matter, or favorably disposed towards it, are respectfully requested to extend this notice.

HENRY COLMAN,

Commissioner of Agricultural Survey.

Feb. 24.

FIFTH AGRICULTURAL MEETING.

INDIAN CORN

We continue our reports of the Fifth Agricultural Meeting; the subject under discussion being Indian corn.

Mr Meriam, of Tewksbury, on a visit to Poughkeepsie in 1838, found among those enterprising and intelligent farmers of Dutchess county, N. Y., that Indian corn was a crop highly esteemed, and upon which great reliance was placed. A farmer there with one hundred acres of land, would calculate to raise his five hundred bushels of corn. This valuable crop among our farmers had been much neglected.

The Poughkeepsie farmers could obtain manure for one dollar and fifty cents per load, but in many cases they preferred ploughing in green crops. They planted more to the acre than it was our habit to do, and they were extremely particular in the selection of their seed. All these were points in their cultivation to be approved and imitated. In these particulars our farmers were remiss; and especially in the selection of seed.

On his return, he established himself at Tewksbury, Middlesex county. He cultivated eight to nine acres in corn. He had made several experiments in the different kinds of corn. He had tried the large Dutton, the Canada, and the Brown corn, which had been so highly commended in the Monthly Visitor. He wrote to Mr Brown, and having obtained the seed, he found that in its color, compactness and size, it entirely corresponded to the description given of it.

He planted the Brown corn three days before the Dutton. It was fit for boiling when the Dutton corn was setting for ears. It was earlier than the kind known as the Phinney corn. The Phinney corn he preferred to the Canada. He selected his seed of the Brown corn from stalks producing two ears to a stalk. In going through his field he found much of it producing two, some of it three ears to a stalk. His corn was ripe the last week in August. Had he planted only the Brown corn, he should have obtained forty bushels more than he did. His Brown corn yielded 64-1-4 bushels per acre. In the autumn we had a severe gale, by which the corn suffered severely, where ever it was exposed, and the crop was greatly lessened. His Brown corn had passed the season of danger before this storm took place.

With respect to ploughing, the work among us was imperfectly executed. Foreign agriculturists perform their work in stirring the ground with horses. Ameri-

cans do it with mcn. His own experience has satisfied him that the ground should be well manured, as vegetables require good feeding as much as animals. He is of opinion that in ploughing, the ground or sward should be completely inverted. The heat and light must be excluded, or the vegetable matter will not be decomposed.* The piper grass will make its appearance and injure the crop! Heavy lands should not be deeply ploughed. When the light and heat are not excluded, the sward will not be decomposed. He would harrow the ground after spreading his manure two or three times. Rolling it after ploughing, serves to exclude light and heat. With regard to planting, he would not manure in the hill. It is unphilosophical. It is like feeding an animal too high; like giving a pig pure Indian pudding and then wending up the fattening process with dish-water.

Mr Meriam was of opinion that the great error of our farmers was, in going over too much ground; and in not cultivating well what they undertook to cultivate. Under poor cultivation, Indian corn was often a losing crop. By good cultivation, with less labor and expense, a farmer might obtain from one acre as much as is now by imperfect cultivation, obtained from three acres.

The proper mode of planting depends somewhat on the ability of manuring the land; the frequency or nearness of the hills should bear some correspondence to the richness of the soil. He had a neighbor who spread his manure and manured his corn in the hill likewise. In planting, he put five or six kernels to the hill, and selecting the best, left three stalks in a hill. His crop was more than eighty bushels to the acre. He did not plough more than two inches deep. Had he ploughed six inches deep, and excluded the light and heat from the inverted sward, his crop would have been better.

In regard to hoeing, he would say, if the lands are inclined to suffer from drought, he would use the cultivator in preference to the hoe. On dry lands no hill should be made: on spongy and wet land, corn should be hilled. In the harvesting of corn, he deemed it not advisable to cut it up at bottom, but when the corn was well forwarded, to top the stalks and allow the crop to ripen fully on the butt before it is gathered.

Mr James W. Carter, from Lancaster, Worcester county, then addressed the meeting.

He began by saying that he did not feel at liberty to decline the call of the Chair. The President was accustomed to lay all his friends under contribution when he thought it would serve the public benefit. To speak here upon agriculture, was a new duty to him. He had been, much of his life, accustomed to give instruction, but he was not used, and he should not undertake, to give instruction to farmers in regard to their duty. For his own part, he had been much more familiar with turning

periods than with turning furrows. He had spent in rural scenes and occupations. Until he was twenty years old, he had been accustomed to labor on a farm. His early attachments to the useful and delightful pursuits of agriculture, so far from being abated, had daily become strengthened. The remainder of his life he considered devoted to agriculture. The pursuit constantly became more interesting to him, and he found its practical labors a source of pure and grateful enjoyment.

He felt deeply the importance of this subject in all its bearings upon individual and social comfort, and in its political and moral aspects. Its importance could not be overestimated. It gave him great pleasure to meet so large and respectable an assembly, devoted to agricultural inquiries; and he trusted that these discussions and the mutual interchange of experiences and opinions would lead to the development and establishment of important principles as a safe basis for practice. Agriculture has been too much matter of guesswork, or of slavish and blind adherence to former practices. He would have it matter of inquiry and of sound sense.

On the subject before the meeting, the cultivation of Indian Corn, he had been much gratified and interested by the remarks of his friend from Northampton. His

*This philosophy is somewhat questionable; but we are to be understood as acting as mere reporters.

Here is a new name for the *trifolium repens*, or creeping wheat, otherwise squinch or quack grass. This grass is a perfect alias, and has as many names as are to be found in the first chapter of Matthew.

It was really quite a tolerable crop as it was. Eighty bushels per acre is no trifling. We think Mr M. must have labored under a mistake as to the ploughing being but two inches, and regret that we cannot send him a proof for correction, if correction be necessary.

object was to save labor and manure. This he himself admitted was a capital object. This labor and manure in farming operations, constituted all the trouble in farming; but if he should attempt to get along without labor and manure, his crops, to use a school phrase with which he was familiar, would be "minus." His soil needs much cultivation. It is a heavy soil resting upon a clayey subsoil. He had found one change in the mode of cultivation advantageous. The old mode of making big round his corn he had abandoned, as a useless expense of labor and of no advantage to the crop.

In preparing for his corn crop he divides his manure into two parts; that which is green he spreads upon the land at the rate of twelve to twenty buck loads per acre and ploughs it under four or five days before planting. He ploughs with as much evenness and exactness as possible. This fine compost manure made in his yards in preceding summer, he puts into the hill at planting. This is the first food of the plants, prepared for their immediate use. As the plant advances, and extends its roots, it finds the long manure ploughed under, the gradual decomposition of which, has by that time been brought into a condition to be taken up by the plant. He deems it of great importance to plant in straight rows and to have his furrows even and true. He uses the cultivator, and spreads it so that all the land between the rows may be thoroughly stirred without disturbing the sward and by having the rows straight, he can approach the more nearly to the plants. He is of opinion that the oftener he uses the cultivator among his corn, the better the crop will be. He cuts up the superfluous stalks and by his mode of cultivation, he has very much increased his products. He now gets eighty bushels to the acre. He objects to planting corn in drills, as he thinks it increases very much the labor of cultivation, with any additional profit. Immediately after harvest he puts on another dressing of manure and ploughs it in, turning up the sod; as his experience is in favor of this practice.

(Should this report reach Mr Carter's eye, we hope we will do us the favor of stating the next step in his progress; what crop follows his corn; and what reasons would give for reverting the sod at this second ploughing, instead of cultivating a grain crop by merely harrowing it in as is the approved practice of many excellent cultivators. Does he find the sward completely decomposed after one crop; or does he derive an advantage from hastening its decomposition by thus breaking it by the plough? H. C.)

Mr Allen Putnam continued the discussion.

He had made experiments with six different kinds of corn. Some which he received last year from the Commissioner, and which he called the Colman corn, he did not approve, as it yielded fifty bushels only per acre. (Now as we did not originate the corn, and gave it to him not for its productiveness, but its early maturity, we begged him at once to alter the name.)

The second, was the Richards' corn, which did better (so much for Mr Richards.)

The third was the Bosson corn; sometimes called the Parker corn, and originally from Canada. This produced fifty five bushels per acre.

The fourth, the celebrated Tree corn, which gave six or two bushels to the acre. This kind he pronounced to hate for our climate.

The fifth, the Tuscarora corn, which was first introduced as a garden corn. It was highly productive. The kernel was large, sound, and brittle. The meal was sweet; and on warm and good lands, the yield excellent. This gave sixty bushels per acre.

The sixth, the Dutton corn, did not do so well as the Brown corn, which was the kind they customarily planted. The Dutton would measure most on the cob in a basket; but when shelled, compared with the Brown corn, it would yield less by one quart in a bushel.

He was not desirous of increasing the number of ears upon a stalk. The number of ears on a stalk seemed he gained at the expense of the size of the ears and the quantity of corn. He referred again to the great value of the harrow in the cultivation of this crop, and the importance of seeding liberally.

He approved the practice of harvesting his crop coming up at the bottom soon after it was gathered, and would cure well though the car were but slightly and imperfectly glazed. The corn which was thus managed had proved in the kernel the most plump and best. The larger the stalk of the corn the better the stock would stand; and though they had had foggy and wet weather after the corn was thus set up in the field, it had remained uninjured.

The further discussion of the subject was continued the next meeting. II. C.

SIXTH AGRICULTURAL MEETING.
The Sixth Agricultural Meeting was held on Thursday 20th inst., and was very fully attended. The evening was managed by Mr E. H. Derby, Mr Dodge, Clark, Mr Putnam, Mr Cook, and others, and much interesting matter was brought out.

The Hon. Wm. Foster likewise addressed the meeting on French and Spanish practices in husbandry, which, from several years' residence, he had been clear, and pointing out in what respects our farmers differ from them many useful hints.

His report is in the hands of the compositor, but the of our columns forbids its insertion. These reports are happy to learn, are looked for by our readers interest, and we shall try to continue and hereafter them in circulation fresh from the mint. If we more get up with the team, we shall hope to keep and not be travelling on in this style far behind, and g out " Mister, let us get on."
H. C.

SILK MEETING.

particularly invite the attention of all interested to the discussion of the subject of the silk cul on the second Thursday in March. We hope it will be fully attended by our friends from a distance, and to many will come prepared not only to say, but to what they have done. Northampton, Hartford, West, Bolton, Harvard, Portsmouth, Providence, &c. 1. tation! the whole. Look well to the right! Dress!
H. C.

THE EDITOR OF THE N. E. FARMER:

In reply to my remarks at the State House relative to Indian corn, you make me say that after having a ten or twelve loads of manure to the acre, I put three loads more in the hill. I said, or meant to put ten or twelve more were put in the hill, making twenty-two or three. Also, you make me say in other, that the crop in 1859 was 77 bu. per acre, and that, that it was 77 bu. and 49 qts. The average of the large kind was 77 bu. and on one acre (the it was 87 bu. and 19 qts. You also expose my ignorance of figures when you make me say that corn 3 ft. gives 4360 hills to the acre. My corn was that number of hills to the acre, but it was more than 3 ft. apart. were eight bundles in a stack—you say four.
ALLEN PUTNAM.

make these corrections with pleasure. It is extremely difficult to report numerical statements, and if we commit the unpardonable sin of misstating a large by putting down 40 instead of 20, we think we are very pretty well. We know the habitual exactness of a respected friend; but we believe "he made himself" some of these things, since some of our contemporaries seem to have understood him as we did.—H. C.

BRIGHTON MARKET.—MONDAY, Feb. 24, 1840.
Reported for the New England Farmer.

Market 350 Beef Cattle, 14 pairs Working Cows and Calves, 1200 Sheep, and 100 Hogs.
But 50 Beef Cattle unsold.
Sales.—*Beef Cattle.*—Sales were very dull and the obtained last week were not sustained on the market. We quote First quality, \$6 75. Second quality, \$6 25 a \$6 50. Third quality, \$5 25 a \$5 75.
Working Oxen.—A very few sales only were effected.
Cows and Calves.—"Dull." We notice a few sales at \$32, \$38, \$40 and \$45.
Hogs.—Nearly half at market were rather ordinary. At \$2 50, \$3 25, \$3 75, \$4 25 and \$5 00.
Sheep.—Those at market were previously contracted for at 4-78. Two thirds barrows. A very few only retained.

THERMOMETRICAL.

Reported for the New England Farmer.
Use of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded dry exposure, week ending February 23.

Feb., 1840.	7 A.M.	12 M.	5 P.M.	Wind.

FARMS FOR SALE.

For sale, a farm in a high state of cultivation, situated in the southerly part of Needham, bordering on Charles River, pleasantly situated, and within one quarter of a mile of Needham and Dover Mills, and within six miles of Dedham Court House, containing about 55 acres of land suitably divided into tillage and pasturing; well watered, and mostly fenced with good stone walls.

There is a young orchard containing about 150 choice Fruit Trees in a flourishing state; a large and convenient dwelling house; a new Barn 40 by 60 feet, with a store and granary connected with it, and cellar under the whole, with a first rate pressery. If sold as one lot, the whole, with April next, the house and store will be let. The store is convenient and well situated for trade.

Also—a small farm situated in the northerly part of Dover, and within half a mile of the above named mills; a desirable situation for a mechanic, containing about 30 acres of land, and well watered; with house, barn, and out-buildings.

The stock and farming utensils of the said farm will be sold at public auction on Wednesday, 15th March. For further particulars inquire of LEONARD BATELLE, in Needham, near said farms, or CALVIN FRENCH, on the premises.
Needham, Feb. 26, 1840.

FARM FOR SALE.

For sale, a superior farm of nearly fifty acres between Boston and Lowell, 15 miles from the former place; on which is situated a convenient dwelling house, barn, and other buildings in good repair, and an orchard of choice fruit trees. For further particulars inquire of the subscribers, No. 52 North Market Street. JOSEPH BRECK & CO.
February 26.

TO FARMERS.

500 casks Lime, of good quality, for sale by the subscribers at their wharf Front Street.
We would remind consumers of this article that the casks are larger and have at least one fourth more in quantity than in former years. Price 112 cents per cask.
CARTER & WILLARD.
4W

WEBSTER'S SEEDS.

The subscribers beg leave to state that they have received Mr Webster's Seeds; those who wish to experiment upon them and obtain a portion, had better call or send soon. They are as follows:—

- Hop-ton Winter Oats.
- Essex do. do.
- Dutch Poland Spring do.
- Kent Tartary do.
- Essex Winter Beans.
- Manford's Garden, or Horse Beans.
- Yorkshire Profit Beans.
- Suffolk Harard Tick do.
- Whittington Winter Wheat.
- Surrey Golden Drop do. do.
- Winter Tares, or Vetches.
- Spring Tares, or Vetches.
- Italian Rye Grass.
- Pacey Rye Grass.
- White Globe Turnip.
- Pomeranian do.
- Swedish do.
- Red Tankard do.
- Yellow Scotch do.
- White Tankard do.
- Purple Top Hybrid.
- Red Globe Mangel Wurtzel.
- White do. do.

We have also received some of the Early Hope Cabbage Seed, which was tried last year in New York and proved to be superior to any Early Cabbage hitherto known in the country.

We have now in New York, which will come to hand in a few days, some of the Chevalier Barley, which we shall be happy to offer to our customers.

It has been understood by some that the seeds were left with us for gratuitous distribution. We wish to correct this mistake as it is not the case. We were directed to dispose of them at a small advance, sufficient to pay for our trouble, storage, &c. JOSEPH BRECK & CO.
Boston, Feb. 12, 1840.

SEEDS FOR HOT BEDS.

- Early London Cauliflower.
 - Early Dutch do.
 - Early York Cabbage.
 - Early Hope do. (very superior.)
 - Early Broccoli, sorts.
 - Saint's Early Frame Cucumber.
 - Girol's White Solid Celery.
 - Do Red do.
 - New Dwarf Red Solid do.
 - Do White do.
 - Superior Double Curled Parsley.
- For sale by JOSEPH BRECK & CO.
February 19.

MISCELLANEOUS.

For the New England Farmer.

CONSUMPTION.

She was a bright young creature, full of joy
And hope—the very life of the loving
Inmates of her home. Health was in her eye,
Gladness in her step. And a meek, trusting
Spirit dwelt in a heart all purity.

She was, to those who knew her, as the stars
To the lone traveller on his midnight way:
Or, as the smiling, early flowers of spring
When first they yield their fragrance to the air
In all its freshness, are to him who greets
Their bright return with deep, impassioned gaze.

Pure as the mountain dew was the rich strain,
Of love that flowed within her heart—a heart
Formed to feel sympathy with human woe.
Sorrow ne'er cast its shadow o'er her path;
Grief never dimmed the lustre of her eye;
Love was her portion—for her parents, brothers,
Sisters, all summed up their deep affections
And poured them out on her—then dearest one

A few short years had glided by and she
Was still beside them—still the same loved one,
But oh! how changed. Consumption's withering form
Had passed and breathed on her an influence—
Blighting. Affection wildly called on death
To stay his hand; but ah, how vain the prayer:
Swiftly he sent his viewless arrow forth
And lodged it in the fountain head of life
Poisoning its waters. Oh! it was
Agony—deep, unspeakable—to gaze
On one so loving and beloved, and mark
The progress of disease filling the clear
Bright spring of life with foul impurities:
Daily to watch with fear the wasting frame,
And cheek, and feel the light of hope depart,
As the heart-rending truth rushed on the mind
That she, indeed, must die.

I BOW NOT YET.

I bow not yet—there's that within
Can soothe the pain of every care,
Can lift my drooping spirit up
And give bright hope a welcome there
'Tis the best thought that there is one
So full of mercy, truth and love
That when I raise my heart to prayer
He listens from his throne above—
And bids me—fearless—onward press.
Nor heed the changing hues of time,
To look beyond this cheating earth:
To that bright world—that blissful clime—
Where friendship, love and truth shall meet,
Pure hearts unite in converse sweet—
And immortality be mine.

THE FARMERS' COMPANION.

Or Essays on the Principles and Practice of American
Husbandry with the Address prepared to be delivered before
the Agricultural and Horticultural Societies of New Haven
County, Connecticut, and an Appendix containing Tables
and other matter useful to the Farmer. Second edition. By
the late Hon. Jesse Buel, conductor of the Albany Cultiva-
tor. For sale at the New England Farmer Office.
February 19. JOSEPH BRECK & CO.

VEGETABLE CUTTER.

Wells's New Improved Vegetable Cutter. This machine
is calculated for cutting up vegetables and esculent roots for
fodder, and is one of the most useful and economical ma-
chines that the farmer can use. The subscribers feel great
confidence in recommending this machine to the public;
they are aware that it has been long wanted and they now
offer a machine that cannot fail to give satisfaction upon a
fair trial. It will cut with ease from one to two bushels per
minute, in the best possible manner, and is not liable to get
out of order, being made in the most substantial manner.
No farmer should be without one of them. For sale at the
Agricultural Warehouse, 51 and 52 North Market Street.
December 18. JOSEPH BRECK & CO.

BONE MANURE.

The subscriber informs his friends and the public, that
after ten years experience, he is fully convinced that ground
bones form the most powerful stimulant that can be applied
to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone,
and solicits the patronage of the agricultural community.
Price at the Mill 25 cents per bushel; put up in casks and de-
livered at any part of the city at 40 cents per bushel, and no
charge for cricks or carting.

Also, ground Oyster Shells.

Orders left at the Bone Mill, near Tremont road, in Regis-
ter, at the New England Agricultural Warehouse and
Seed Store, No 52 North Market Street, or through the Post
Office will meet with prompt attention.

NAIUM WARD.

FLOWER SEEDS—CHOICE VARIETIES.

JOSEPH BRECK & CO. have received a choice assort-
ment of Flower Seeds from England and France, which, in
addition to what have been raised under their own inspec-
tion, embrace the finest collection to be found in the coun-
try, including all the new Annuals, Biennials, and Perennials
worthy of cultivation; neatly done up in papers at 6 1/4,
12 1/2, and 25 cents each. For sale at 51 and 52 North
Market Street.
February 5.

SCIONS OF FRUIT TREES FOR SALE.

The collection of fruits cultivated at the Pomological
Garden consists of more than 1400 varieties of the Apple,
Pear, Plum, Cherry and Peach. Scions of all those which
have been proved are offered to nurserymen and others. Gen-
tlemen wishing to send collections of American fruits to
their friends in Europe can be furnished with most of these
of first rate quality. They are warranted true to their names,
and are in all cases cut from fruit bearing trees.
Salem, January 25, 1840. ROBERT MANNING.

FOR SALE.

An excellent Farm, pleasantly situated about 20 miles
from the city, containing about 100 acres. For full descrip-
tion, particulars, &c. inquire at this office.

Also, a situation wanted by a man with a small family to
carry on a farm. 4w
January 30.

ROHAN POTATOES.

For sale at the New England Agricultural Warehouse and
Seed Store, No. 52 North Market Street, at 85 per barrel.
October 16. JOSEPH BRECK & CO.

GARDENER WANTED.

Wanted, a Gardener of steady habits, that understands
raising vegetables and taking care of fruit trees. An Ameri-
can, with a small family, would be preferred. None need
apply without good recommendations.
February 19.

THE STATE REGISTER.

Containing the New Tariff for 1840, the Insolvent Law,
New List of Post Offices, State, City and United States
Authorities, Judges, Counsellors, Attorneys, Sheriffs and
their Deputies, Masters in Chancery, Justices, Notaries,
Coroners, Clergy, Physicians, Militia, Army and Navy,
Banks and Insurance Companies, besides other useful mat-
ter. For sale by JAMES LORING, No. 132 Washington
Street.
February 12. 3t

SITUATION WANTED AS GARDENER.

By a married man with no incumbence but his wife's—
of whose practical experience is known to the amateurs of
this vicinity. Any commands addressed to Joseph Breck &
Co for M. I. will be promptly attended to.
Feb. 5.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO. at the New England Agricul-
tural Warehouse and Seed Store, Nos. 51 and 52 North
Market Street, have for sale, Green's Patent Straw, Hay or
Stalk Cutter, operating on a mechanical principle not before
applied to any implement for this purpose. The most pro-
minent effects of this application, and some of the consequent
peculiarities of the machine are:

1. It requires a reduction of the quantum of power requir-
ed to use it, that the strength of a half grown boy is sufficient
to work it very efficiently.
2. With even this moderate power, it easily cuts two bus-
hels a minute, which is full twice as fast as has been claim-
ed by any other machine— even when worked by horse or steam
power.
3. The knives, owing to the peculiar manner in which they
cut, require sharpening less often than those of any other
straw cutter.
4. The machine is simple in its construction, made up
put together very strongly. It is therefore not so liable
to the complicated machines in general use to get out of order.

AGRICULTURAL BOOKS

JOSEPH BRECK & CO. offer for sale a great variety
of Agricultural books, among which are the following:

- London's Encyclopedia of Gardening.
- " " of Plants.
- " " of Agriculture.
- " Suburban Gardener.
- Forbes's Hortus Wolfrunensis.
- Practical Agriculture, by David Low.
- Clapton's Agricultural Chemistry.
- Herez on the Cultivation of the Carnation and other F-
rist Flowers.
- The Florist Cultivator.
- Friedmann's Gardeners' Assistant.
- Fessenden's American Gardener.
- " Complete Farmer.
- Kennick's Orchardist.
- Manning's First Book of Fruits.
- Sayers' Fruit Garden Companion.
- " Flower Garden Companion.
- Treatise on Sugar Beet, by David Lee Child.
- American Swine Breeder.
- Mowbray on Poultry.
- Monography of the Genus Camellia.
- Donnan's Silk Manual.
- Cobb's "do
- Kennick's Silk Growers Guide.
- Whitmarsh on the Mulberry Tree and Silk Worm.
- American Farrier.
- Parley's Cyclopaedia of Botany—The Young Florist.
- Weeks' Treatise on Bees.
- February 5.

ELEMENTS OF PRACTICAL AGRICULTURE

Just received, a supply of the Elements of Practical Agricul-
ture, comprehending the cultivation of plants, the husband-
ry of domestic animals, and the economy of the farm. By L.
Low, Esq. F. R. S. E., Professor of Agriculture in the Un-
iversity of Edinburgh. Second edition, with numerous ex-
gravings; 718 pp. London published. For sale by JOSEPH
BRECK & CO., No. 51 and 52 North Market Street.
February 5.

GARDEN MATS.

For sale at the New England Farmer, 100 dozen Garden
Mats, of extra quality, for covering hot beds, &c.
Feb. 12. JOSEPH BRECK & CO.

N. E. FARMER.

MEMORIAL OF THE COMMISSIONER

of the *Agricultural Survey of Massachusetts, on a Board of Industry, &c.*

Presented to the Hon. Senate and House of Representatives of Massachusetts, now in session in Boston:

By the memorial of the subscriber, Commissioner of the Agricultural Survey of the State, respectfully—

That the domestic industry of the State, and especially its agriculture, in its connexion with national wealth, with the comforts of every class and condition of its people, and with good morals, has its basis in the most liberal encouragement and patronage of the government.

That a faithful and enlightened regard to agriculture in Massachusetts has eminently distinguished it among her sister States. In her endowments and annual bounties to agricultural societies, in her geological and agricultural surveys, and in the premiums offered for the production of wheat and sugar, she has made a generous provision of encouragement of this great and useful art; and with a sound discretion has expended money, which has already given back, and is in the process of making the most abundant returns.

That the proper and useful direction of this bounty is a subject of public concern. It may have done good; and yet not all the good which it might do, or may be made to do. In the official reports in which your memorialist holds the command in reference to this subject, he trusts it will be deemed intrusive or uncalled for, if in the manner he presents to the Legislature his views upon the manner in which the patronage and power of the government may be rendered more efficient, or may have yet proved; or may be applied in a more judicious and eligible. At the same time he trusts the Legislature will do him the justice to bear in mind that he presents these views with the respect and honor that are due to the body which he has the honor to address, combining in so high a degree, the wisdom and intelligence of the Commonwealth.

That the disbursements of the State, on account of agricultural societies within the last two years, amount to \$8,768; on account of bounties on the production of silk, within that time, have been \$1,000; on account of bounties paid on the production of wheat, within the last year, \$9,250 14; and a total of \$18,332 28. The expenditures on geological and agricultural surveys are also on the account of the Legislature. It will be seen under the present circumstances, that the State has not been liberal. It is believed that the objects for public patronage seldom present themselves, and the good already resulting from the present management, shows the wisdom and sound judgment of the appropriation. Your memorialist is convinced that a large portion of this patronage, rather of this expenditure, may be withdrawn, and the remainder applied with more advantage than it has yet been.

Your memorialist is of opinion, that there is no further occasion for a bounty upon the production of wheat. The law offering this bounty, may be supposed to have had two objects in view: the first, that of determining the capacities of the climate and soil of the State for the production of this crop; the second, by a comparison of the different modes adopted in reference to the soil, the kind, the quantity and the preparation of the seed, the time of sowing, the kind and quantity of manure applied, the use of lime, plaster, and ashes, and any diseases or accidents which may have occurred, that of ascertaining what is the best mode of cultivating the crop, and how the diseases or accidents to which it is peculiarly liable, should be guarded against or prevented.

In respect to the former object, the capacities of the soil and climate of Massachusetts to the production of this crop, the reports of the two years during which the bounty has been offered, are amply sufficient for its determination. It will appear from these returns that there is no natural incapacity either in the soil or climate of Massachusetts, making all ordinary and reasonable exceptions of particular and limited localities, for the perfect production of this valuable crop.

In respect to the second object, the determining the best mode of cultivation, this has not and cannot be obtained under the law, at least in its present form. The returns, in the first place, in the requisitions made by the law in respect to the circumstances of the cultivation, are too meagre and imperfect to lead to certain and valuable conclusions. In the second place, the premiums offered are in themselves too small to induce to that exactness and carefulness of culture and observation, which are indispensable in order to settle with certainty many contested or dubious questions in relation to it. This object, however, which is indeed of the highest importance, may be attained, as will be hereafter shown, by another mode. In the opinion, therefore, of your memorialist, the continuance of the law offering a bounty on wheat is not necessary for the objects, which are presumed to have induced its enactment.

With respect to the bounty upon the production of silk, the same remarks, in a degree, apply as to the law authorizing a bounty upon wheat. The capacity of the soil and climate of the State, in respect to the cultivation of the best kinds of mulberry trees for feeding the worms, and in respect to the rearing of worms, and the production of silk of the best quality, has been fully demonstrated; and the profitableness of the production of raw silk as a branch of domestic and household industry, has been as fully established. This object of the law has then been attained. The procuring of information as to the best kinds of trees, and the best modes of management in regard to the worms, though an object of the highest importance, is not at all provided for by the law. This, however, as your memorialist hopes to show, may be attained without any new or direct expense to the State, under another form.

With respect to the bounty upon sugar manu-

factured from beets, it is not known to your memorialist that any claim has yet been made. The law is limited to five years from its enactment. Whether it be competent for the Legislature under these circumstances to rescind it, it is not for your memorialist to offer an opinion; but as the only valuable object to be attained by the State under the law, is the ascertainment of the practicality of the production as far as the raising of the beets and the manufacture of the sugar are concerned, and as these matters are already fully established, it does not appear that any public advantage is to be gained by continuing the law beyond the prescribed term; or indeed at all, if it be consistent with the character of the statute to repeal it before it will expire of itself. The law, in its present form, is likely to avail little in regard to the matter of the greatest importance to the agricultural community; that is, the determining the best and proper mode of cultivating the beet, and the proper and best mode of extracting and manufacturing the sugar; the value and uses of the pomace in feeding stock or for other purposes; and the expenses or profitableness of the culture of the vegetable or the manufacture of the sugar. Another point, perhaps of more importance than any other, and which is not likely to be attained under present arrangements, is the ascertainment whether the manufacture of sugar can ever be made a certain and profitable branch of domestic or household industry, so that every family may with advantage supply themselves with this great and necessary article of home consumption.

In respect to many of the bounties or premiums bestowed for agricultural objects in the State, there seems to your memorialist to be one cardinal failure or defect. The legitimate object of all such bounties and premiums is not solely to excite and encourage enterprise, inquiry, and experiment, but mainly to obtain useful and practical information, which may be diffused among farmers. We desire to know not only that a thing can be done, but how it can be done; not only that a particular vegetable or crop can be raised, but in what manner and by what particular process this may be effected. Under the laws of the State authorizing bounties upon wheat, sugar, and silk; and under the operations of the agricultural societies in the use of the money granted them by the State, this is not always provided for; and, in a considerable measure, it is not done. Whether better arrangements can or cannot be made, is matter of useful inquiry. Your memorialist is of opinion that a beneficial alteration in this matter may be made, in respect to the annual grants made by the State to agricultural societies; and, without designing to cast any censure whatever upon any persons or any society, yet he would respectfully express his conviction, that those to whom the application of this public-spirited bounty is entrusted, should be held to a more exact accountability. At present, the amounts expended, and the objects for which they are given, with the persons' names upon whom they are bestowed, comprise nearly all that are returned to the office of the Secretary of the State; but your memorialist

conceive, that the objects for which these bounties are bestowed would be more effectually accomplished by a greater exactness and fulness in these returns.

It is known, likewise, that complaints are frequently made against the manner in which these premiums are awarded and cattle shows conducted. Complaints are often made in respect to the objects selected for premium and the conditions under which the competition is regulated. Now whether these complaints be well or ill-founded, your memorialist will give no farther opinion than that in many cases improvements might be made, which would take away all just ground of complaint. The duty of managing and awarding these premiums is not always a desirable office; and it would relieve those on whom this duty devolves from an unwelcome responsibility and conduce to the objects of the bounty, if the subjects of premium, the conditions and rules of competition, and the mode of awarding them, could be brought directly under a central board of control.

It seems, in the next place, to your memorialist, exceedingly important that some mode should be adopted to ascertain, with as much exactness as the nature of the case admits, the actual products of agriculture within the State. True political economy differs not at all, except in the extent of its application, from true household, private, or domestic economy. The wise merchant or farmer will seek to possess himself in the most exact manner, of the knowledge of his condition, his stock in trade, his income, his expenditures, his gains, his losses, and the actual results of his business. A State or political community should in like manner become acquainted with its actual condition, and especially with all the applications and results of its industry; for this is indeed the great source of its wealth, the right arm of its power, the only true foundation of its independence. It should become acquainted with its own capacities and powers; and learn how far they are called out, how they are applied, how they may be best applied, and to what extent she may rely upon them; and especially how far she may rely upon them for the supply of her necessary wants, and to what extent and in what way they may be made the foundation of social wealth and independence.

Every part of the civilized world seems to have waked up to the importance and value of statistical information; and no knowledge is likely to lead to more useful practical results. The smaller the community, the more directly practical and efficient is such knowledge. The statistical returns of the mechanical and manufacturing industry of the Commonwealth, obtained and published three years since by direction of the government, are universally admitted to be one of the most valuable documents ever published by the State or in the State. It has exalted the credit of the Commonwealth in the highest degree at home and abroad; and given her the command of capital and resources for use and improvement, which otherwise she might not have been able to obtain. It has secured to her a rank among her sister States which otherwise, with her limited territory and disordered soil, she could hardly have maintained. It has inspired in her own citizens an honest pride, a self-respect, a feeling of self-dependence, which naturally grow into an attachment to home, and quench the desire of emigration. More especially, and above all, it has revealed and established, even in the most humble

and the most sceptical minds, the great truth, that in honest, enlightened, well-directed, persevering, and productive industry, there are to be found a means of wealth, an instrument of power, a source of comfort, a security to morals, and a ground of independence, which the underlaying of her whole territory with mines of gold would not supply.

What has been done for manufacturing and mechanical industry, your memorialist is anxious should be extended to every other branch of productive labor, and more especially to agriculture. It will not be difficult or expensive to accomplish it. It may reveal in many respects a mortifying deficiency and a blameable neglect. The knowledge of the facts in such case will more than any thing else, conduce to amendment. It may disclose to our gratification and surprise, more favorable results than we apprehend. Such a case would stimulate ambition, and encourage to greater exertion. To any event an accurate attainment of our condition and products in this matter would have a powerful and favorable influence upon our agriculture; and would prove a most important step in the way of improvement.

It is believed, in the judgment of some highly intelligent and observing men, that taking the whole territory into view, Massachusetts does not produce half a peck of Indian corn to an acre. If this fact could be ascertained, in an authentic form, it would, your memorialist believes, at once awaken the farmers to the great value of this crop, and the losses suffered by the neglect of its cultivation. It would at once occur to them that it could not be difficult for Massachusetts to raise at least one bushel of corn to the acre, or as many bushels of corn as she has acres in her territory. To say nothing of the fodder, and the means consequently of increasing her live stock, this would be the actual creation, out of her soil, of four million five hundred thousand bushels of Indian corn. In such case we may consider half the product in grain as the clear profit of the crop. What an advantage to our habits, our comfort and our power of usefulness, if then, as clear gain beyond the cost of labor and cultivation, we could produce annually in the State two million bushels of Indian corn. What mine of gold in any country would be comparable to this? But this is only one article of agricultural produce. The knowledge of other products would be equally and similarly useful.

Your memorialist is further of opinion, that these several objects may be accomplished without any additional appropriation or expense to the Commonwealth, beyond what it now pays. He asks leave further to state his views of the ways and means by which this may be effected.

Your memorialist would therefore respectfully suggest, that there be constituted, within this government, a Board of Domestic Industry, to consist of one delegate from each county or congressional district of the State, to be joined by the Committees of the Legislature on Agriculture and Manufactures, and the Governor and Lieut. Governor of the Commonwealth, ex officio.

That the delegates and a secretary to the Board, shall be appointed by the Governor and Council, and shall receive for travel and attendance such rate of compensation as may be deemed just.

That the Board shall meet once a year, on the third Wednesday in January, at the State House, in Boston, and their session shall never be extended over ten successive days.

That it shall be the duty of this Board, annually, to examine and report fully to the Legislature the condition of the agriculture and manufacture of the Commonwealth; and suggest such measures as may conduce to the benefit of these great branches of industry, and the individuals directly concerned in them.

That every agricultural society in the Commonwealth shall be required, annually, to make a perfect return of its affairs; the number and names of its members, the amount of its own funds, and the manner in which it uses or applies the money received from the State.

That the several agricultural societies be allowed to receive yearly, one half the sum which is authorized to be paid to them by law; and that the other half shall be placed at the disposal of a Board of Industry, to be given in the State, in premiums for distinguished improvements, cultivations or inventions.

As for example, let a premium of one hundred dollars be given for the best and most exactly conducted experiment in growing wheat or other grain requiring that such experiments shall be conducted in the most careful manner, according to prescribed conditions, and in a way to ascertain, as far as practicable, important, or doubtful, or contested points, in reference to the crop on which the premium is offered.

Let a premium of one hundred dollars be given for the best and most exactly conducted experiment in producing silk, conducted with a view to prescribed objects, and detailing fully and exactly every step in the progress, so that the desired formation may be obtained in the most authentic form.

Let a premium of one hundred dollars be given for the best conducted experiment in producing or manufacturing beet sugar, under conditions to be prescribed with objects above suggested.

Let one hundred dollars be given for the best experiment in the application of manures, with a view to test in the most authentic and conclusive manner, the proper use, preparation and application, and the comparative efficiency and value of different manures.

It being understood in all cases that the object of such premiums is, not the rewarding of individual enterprise or skill, but the obtaining of practical and decisive information for the general benefit of the farmers.

As far as the means of the board extend, the board may use their moneys in rewarding any extraordinary agricultural or mechanical invention or discovery, promising to be of public utility.

Or they may import from abroad, models, drawings of any valuable implement; or seedlings of plants which promise to be of extraordinary advantage, for distribution among the farmers; or they may use their funds at their discretion, for other purposes directly connected with agricultural improvement and the advancement of agricultural knowledge.

That the Board of Industry determine the times and places of holding the several Cattle Shows in the State; and that in respect to moneys annually granted by the State for agricultural premium competition for these premiums may be open to any citizen of the Commonwealth, whether or not residing in the particular county where the show held.

Your memorialist further respectfully suggests that the assessors of every town or city in

SIXTH AGRICULTURAL MEETING.

The sixth agricultural meeting was held at the State House on Thursday evening, 20th inst. Mr King opened the meeting and resigned the chair for the evening to Mr Brigham, of Westboro', one of the vice presidents.

The Commissioner had the pleasure of exhibiting to the meeting a sheaf of rice, presented him by E. Dyer, Jr., Esq., of Providence, and for which Mr Dyer will please to accept his respectful acknowledgements. "It was gathered by Mr Dyer from a plantation in Georgia the last spring, and was in the straw. The rice was taken promiscuously from a heap, and was not to be considered as any thing more than a fair sample—the head rice being much handsomer." It was gratifying to those persons who had never seen the plant in a growing state. We should be gratified if Mr Dyer would extend his kindness by giving us at his convenience, some account of his observations in his agricultural tour south.

The Commissioner then presented a letter from Wm. Foster, Esq., containing interesting information respecting the manufacture of butter in France, and suggesting valuable improvements which might be adopted here; referring especially to the machine exhibited at a former meeting, for the perfect expression of the buttermilk, and other matters.—This letter will be given hereafter.

Mr Foster then, as no other opportunity would be available to him on account of his expected absence at the south, was pleased to address the meeting at large, on various miscellaneous agricultural topics, and gave many valuable hints and interesting reminiscences of agriculture in France and Spain, where he resided many years, and became familiar with their practices. He showed himself a most careful observer of every thing of this nature which came under his view, and promises that we shall hear more fully from him on these subjects through the N. E. Farmer. In the mean time, we shall, if time allows, prepare a synopsis of his remarks, to be given at a future time.

The meeting then passed to the order of the evening, which was Indian Corn and the Small Grains. The former subject, with some miscellaneous matters, occupied the remainder of the evening. The meeting was very fully attended.

E. Hasket Derby, Esq., of Boston, at the instance of the Commissioner, addressed the meeting.

Mr Derby was the owner of a farm in New Hampshire, situated on an island in Winnepesaukee lake; and if it would interest or gratify the meeting, he would give an account of its management. He made no pretensions to agricultural knowledge or skill. Farming was not his business. His profession was the law:—but this property coming into his possession, he had done what he could to manage it to advantage.

It was situated in a cold climate: the soil was strong. He owed his success partly to the soil, but in his opinion more to the cultivation. His farm included 500 acres; 170 acres were in wood; 280 acres in pasturage; 50 acres were in mowing and tillage. He had usually eight or ten acres under the plough.

He deemed it best to simplify as much as practicable, the objects of his farming, and therefore the great purpose on the farm was the dairy; and, excepting the necessary supplies for the family, other things were made subsidiary to this primary object. He had now 37 cows, and sometimes had, kept 44,

His farming, in a pecuniary point of view, had been productive, and fully met his expectations. The original cost of the farm and stock was \$4200. The sales in 1838 had amounted to \$1968. This year they had reached \$1500. The falling off was attributable to the decline in the prices of the products. His sales consisted of butter, cheese, and pork. The cows and swine gave him abundant resources for manure, which he applied liberally; on his cultivated grounds putting from thirtyfive to forty buckloads per acre.

The island was in two parts, connected by an isthmus, and of narrow extent. This saved him much expense in the fence required, for one portion being devoted to pasturage and one to cultivation, it was easily divided by a fence extending across the isthmus.

He had this year ten acres under the plough; two acres in potatoes, one in wheat, one in oats, and six in Indian corn. His six acres in corn produced him 400 bushels: one acre of this corn gave him 131 bushels. He applied to the agricultural society of that county for a premium, but he was defeated by a competitor who claimed it for 132 bushels to the acre. The corn was faithfully measured. It was rated at 131 bushels when taken from the field in the cob. Of course it was liable to fall considerably short of this when perfectly dried. It has since been shelled and measured recently, and gave 108 bushels. He considers 12 bushels of corn with the rough fodder included, as equal to one ton of hay. This would make his crop upon the acre equal to eleven or twelve tons of hay for his stock. By what other process could he realize such avails from an acre of land?

The results of his farming operations the two past years, had fully satisfied him. One ground of his success was, that his farm manager was himself directly interested in the results. He conducted matters with great discretion, and his personal interest in the results secured his fidelity.

This farmer in the first place, had what he needed from the farm for the support of his family. In addition to this he gave him in cash 300 dollars per year, and on his sales he allowed, when his butter was sold at 30 cents per pound, (and it had often brought 32 cents,) four cents per pound; on cheese sold, 1 1-2 cent; on pork, 1 1-2 cent. This gave the farmer nearly 500 dollars per year.

His sales the last year were, new milk cheese, 5900 lbs.; butter, 2350 lbs.; pork, 2600 lbs.; besides reserving enough for the consumption of the family.

The male labor on the farm consisted of the farmer and two hired men, who are of course paid by the manager. The female department is filled by one woman, the wife of the manager, (we mention this fact, lest we should disturb the sleep of some forlorn bachelor*)—who performs all the household work and makes all the butter and cheese. (We should like to know at what boarding school or factory she was educated.) Under this management Mr Derby says that he has received from his farm an income of 15 per cent. on the original investment, and the farm is in a course of improvement.

The kind of corn which he plants is known as the Golden Sioux, and was brought by a traveller some years since, from the country inhabited by that tribe of Indians. It is an early as well as productive variety, and in the cold season of 1836, he

*The clause in parenthesis is not a part of Mr Derby's speech, but a more garbure of the cook.

gathered a good crop. He has several times received a premium for his corn.

By the mode of culture adopted, he breaks up his mowing land when it ceases to yield more than one ton to the acre. He takes a crop of potatoes first, lightly manured; the second year corn—sometimes the third year corn; and this is followed by wheat. His wheat gives him 31 bu. per acre. He has raised 40 bu. per acre. His corn is planted 2 ft. in one direction and 2 ft. 8 in. in another. His seed is selected always with particular care. Three plants are suffered to remain in a hill. The corn is cultivated usually with a plough. After wheat the land is laid down to grass and left in good condition.

A principal ground of his success is in his opinion, that he cultivates no more land than he can manure and cultivate well; and a second ground, not less important, is in the limitation of his objects of husbandry. The dairy is the principal matter. No sheep are kept excepting for consumption on the farm. The attention is therefore not distracted among many objects. In the vicinity the soil is as good quality as that of his own farm. Many the islands, however, are not productive. The farmers divide their attention among too many objects. They do a little of many things and much of nothing; and this he regards as the cause of their comparative ill-success.

His corn crop is directly connected with his dairy and available for his cows and his swine. These are his potato crops, which are raised generally without manure.

The meeting was then addressed by Mr Dodge of Hamilton, the secretary of the meeting, on the mode of harvesting corn.

He spoke of the New Jersey mode of harvesting corn, which was by cutting it up at bottom and "stooking" it in the field. He knew, likewise, that a Scotch farmer, the manager of an excellent farm in his vicinity, had been in the habit of planting his corn in drills, and when it was glazed, cutting it up at the bottom and allowing it to become cured in that way. His experience had satisfied him that this mode was to be approved. As soon as the corn was cut the circulations were of course stopped and all danger from frost was over. He thought the labor of harvesting was much increased in this mode; but he was not prepared to say which mode was most eligible. There were very great advantages in encouraging inquiry.

Mr Dodge then went on to speak of the advantages of agricultural reading,* and the benefits which the community received from agricultural periodicals. He referred particularly to the case of a farmer in Southboro', who states that five years ago he kept one horse, one yoke of oxen, and six cows cut 25 tons of hay and made 60 loads of manure. His improvements were such that he now on the same farm keeps two yoke of oxen, twentyfive cows cuts from 70 to 90 tons of hay, and makes 400 loads of manure. This came from husbanding his resources; and all this from reading the New England Farmer. He at that time took one agricultural paper,—he now takes two, and would on no account be without them.

The question was then presented to the meeting, What is the best mode of manuring with corn that has been injured by early frosts?

*Our respected friend here, as the farmers say, showed a disposition to be "breezy," and got through the fence into another field. As, when he let down the bars, let the whole drove in with him, and as the feed was very good "in this other lot," we believe no one was disposed to complain.

Mr Putnam replied, that the best mode of manuring in such case, was to cut it up and stook it at once.

Mr Clark replied, that the proper mode to be adopted with it depended upon the severity of the frost and the condition of the corn. If the corn is open, let it stand upon the hill. This was the most probable means of securing it. If the leaves are not yet touched, the corn will become sound, withstanding this. If the cob is frozen, the corn may be considered like a cooked vegetable, and it beyond cure. In 1836, with him, the leaves on corn were killed. This was the same as cutting off the top stalks. The circulations of the sap were checked. What was then afloat in the stalks was condensed; and the progress or filling out of the corn is at once finished.

He had made some important experiments in the matter of topping the stalks of corn. In one row through the field he topped every other hill, and the remainder as they were until harvest. The crop from topping the stalks he estimated at 20 per cent. The crop from the uncut hills was equal to 48 bushels per acre; from those the stalks of which were cut, it did not exceed 48 bushels per acre. Mr Clark's opinion was then asked by a gentleman present, as to what relation the number of stalks a hill should bear to the richness of the soil. In one case planted an acre of land; manured it liberally; and laid his hills three feet each way. The growth of stalk was excessive, and we understood him to say that the more plants left in the field beyond a certain number, under such high manuring, would cause the yield of corn to be probably diminished.

Mr Clark replied, that the more thickly the corn was sown, where the land was very much enriched, the less would the crop suffer from drought. He planted in hills 2 ft., 3 ft., and 3 1/2 ft. apart, the hills accurately measured. He had left in row 3, in another 4, in another 5 plants,—he kept the ground level. Those which had four stalks gave more corn than those which had three, the five plants gave more than the four. The weight of produce in the case were 38 bushels and 30 bushels. The more thickly corn was planted on rich land the better. On light lands, however, he had found that corn might be too thickly sown.

Cook, of Lenox, then gave his views in relation to corn which had been attacked by frost. In his opinion, an ounce of prevention was better than a bushel of cure. He deemed it best, therefore, considering the uncertainties of our climate, to cultivate corn which came early to maturity. Besides this, it was safest and best, as soon as practicable, to cut it beyond the reach of frost. This was to be done by cutting it up at the bottom and stooking the field as soon as it was fit for that operation.

He considered the death of the leaf as the death of the whole plant; and no farther benefit to the crop was to be expected from its standing. If the corn was soft and then frozen, as in the autumn of 1837, all attempts to save it would be vain. In the eastern parts of this State and in New York the practice of cutting up and stooking the corn in the field as soon as it is glazed, prevails generally, and was strongly recommended by the eminent Judge Buel.

An exceedingly valuable experiment was given to the public through the N. E. Farmer, soon after it was made, and excited particular attention. It has had a beneficial influence upon the practice of farmers.

Other gentlemen participated in the discussion. The meeting was very fully attended; and the general interest is increased instead of abated.—H. C.

MASS. HORTICULTURAL SOCIETY.

Report of the Vegetable Committee on Premiums for 1839.

Asparagus—None exhibited.	
Beans—Large Lima, two quarts, shelled,	
J. L. L. P. Warren,	\$3 00
do Earliest and best Dwarf do. from do.,	2 00
Broccoli—Earliest and best, four heads, A.	
D. Williams,	3 00
Beets—Twelve roots, from do.,	2 00
Cabbages—Best six heads, from do.,	2 60
Carrots—Twelve roots, " " "	2 00
Cauliflowers—Finest four heads, no premium.	
Cucumbers—Best pair before 1st Sat'd'y in	
July, J. L. L. P. Warren,	4 00
Celery—Two roots, none.	
Corn—For boiling, none.	
Lettuce—Finest six heads in the season, J.	
Hovey,	2 00
Peas—Earliest and best, one peck, R. Howe,	4 00
Potatoes—None exhibited.	
Onions—None exhibited.	
Rhubarb—Specimens best, S. Pond,	3 00
Squashes—Summer, none exhibited.

for a fine large squash, gratuity	3 00
To S. Blake " " "	3 00
" J. French, jr., fine Marrow & Lima squashes, premium	3 00
" John Prince, Esq., specimens Brussels	
Sprouts, premium	2 00
" C. R. Lowell, Esq., Egg plants, gratuity	2 00
" G. W. Stearns, Cucumbers, very fine, prem.	4 00
	\$50 00

The Committee regret that so little interest has been manifested the past season, in this important part of the Society's labors; but true it is that during the whole season there were but few exhibitions of vegetables, and those few were but from a small portion of the members of the Society, who have heretofore been ever ready to exhibit their zeal in promoting its interests.

The committee would notice with approbation, the fine specimens of squashes, of the var. Marrow, Crook-neck, Lima, and Valparaiso, exhibited by E. H. Derby, J. French, jr., and S. Blake, Esqrs., at the annual exhibition; and they hope to see more of these valuable varieties the coming season.

The *Rohan potatoes*, exhibited by the Hon. John Lowell, were a very superior specimen, and the finest known to have been grown the present season.

The *Brussels Sprouts*, by John Prince, Esq. were deserving of particular notice. They were very fine, and it is desirable that this valuable production of the vegetable garden should be more extensively cultivated.

The *Giant Celery*, exhibited by W. L. Rushton, Esq., of New York, deserves also marked notice; it was as fine as has ever been exhibited at the Society's rooms.

The *Egg Plants*, by C. R. Lowell, Esq., of three varieties, were large and finely shaped, and uncommonly beautiful specimens.

It is desirable that exertions should be made to produce this luxury in more abundance.

The committee cannot leave this report without earnestly inviting those members who feel an interest in the important part of the kitchen garden, to greater exertions the coming season, and especially to forwarding to the exhibitions of the Society, more numerous specimens of vegetables, in order that its labors devoted to this object may reflect equal credit upon it, as to the other leading branches of cultivation, which engage its prominent attention.

Respectfully submitted,
JAMES L. L. F. WARREN,
Chairman.

THE SILK CULTURE.

Who that is acquainted with the genius and character of our people, for enterprise and perseverance, can doubt, that with the impulse now given to the silk culture in our country, its onward course is to a high destination? And is there an American bosom, in which dwells one spark of patriotism and philanthropy, but that would most ardently wish this?

As statesmen and political economists, is it a wise policy in us to pay out millions to other nations for that which we can just as well produce ourselves? To run in debt to Europe for a single article, to an amount far exceeding all our exports, with the single exception of cotton, 18 or 20 millions of dollars per annum,—to make the balance of trade against us, and thus impoverish ourselves to enrich others?

As *philanthropists*, can we do otherwise than give our best wishes and cordial aid to a branch of industry which will give employment and a comfortable support to thousands in our land, whom poverty, misfortune, age and infirmity have placed in necessitous circumstances; to the children of the poor in our large towns and cities, who are growing up in idleness and vice; to females who are dependent upon the painful and precarious labors of the needle for a scanty subsistence, and to the aged and infirm, who are disqualified for more laborious employment? In the just language of the editor of the *Silk Farmer*, "In all our large cities, where female suffering is the most intense, and in every agricultural district of our widely extended country, the blessings attendant on the progress of the silk culture, will fall with grateful beneficence upon this dependent and neglected portion of our population. A child of twelve years old, or an aged person, unable to follow any laborious employment will attend during the feeding season to as many worms as will make twentyfive pounds of raw silk. The same individual will reel a pound of silk per day. Cannot the reader of this recall to his remembrance some destitute family—some widow with a numerous group of suffering children—to whom a domestic employment of this kind would indeed be a blessing? Or some lonely and aged female, too feeble for labor, too good for the poorhouse, whom a steady fire-side occupation at the silk-reel, might lift up into the sunshine of grateful independence? Considerations of this kind expand the sympathies of the human heart, and make the subject as interesting to feeling and philanthropy, as it ought to be to private interest or commercial enterprise."—*Albany Cultivator*.

A correspondent of the *Albany Cultivator* recommends Congress to lay a duty on foreign silks.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, MARCH 4, 1840.

LECTURES ON MINERALOGY.

We see our friend Teschemacher has announced his design to give next month a course of lectures on Mineralogy, with practical illustrations. The science is full of interest and value, especially to the privileged residents in the country. We must hope he will have a large class. His ability and learning in the natural sciences are unquestioned; and his power of communicating will render them interesting and agreeable. D. C.

THE SEVENTH AGRICULTURAL MEETING.

Was held on Friday evening, 28th ult. Owing to misunderstanding as to the time of meeting, and the attendance of the members of the Legislature upon the exhibition of the pupils of the Blind Asylum, which occupied them until night, the attendance was not so full as at some times; but it was quite respectable in point of numbers. Mr King was in the chair, and in the absence of the secretaries, Mr Allen Putnam, of Danvers, was appointed secretary of the meeting.

The subject of discussion given out for the evening, was the Small Grains.

Before proceeding to the discussion of the evening, Gen. H. A. S. Dearborn, for many years President of the Massachusetts Horticultural Society, and always distinguished for his interest and skill in the useful and practical arts, appeared at the request of the committee of arrangements, and addressed the meeting in an able manner on the general subject of agriculture. We shall be the pleasure of presenting his address to our readers on an early occasion. The report is made, but our space does not admit of its insertion.

The subject of Small Grains being announced for discussion, the Commodore requested through the Chair, that Col. Duncan of Haverhill, for some years President of the Essex Agricultural Society, and highly intelligent and skilled both in the science and practice of agriculture, would favor the meeting with any information he might have, respecting the cultivation of rye by Mr Keeley, of Haverhill, the farmer who succeeded in so extraordinary a manner in the cultivation of rye on an exhausted soil. (The report of this case is given in the Transactions of the Essex Agricultural Society for the year 1832, and in the Appendix to the First Report of the Agriculture of Massachusetts.)

Col Duncan began by stating that he came there to receive and not to impart instruction; but called upon in the way he had done, and did not feel at liberty to refuse his contribution to the valuable object of the meeting.

In respect to the cultivation of rye, his own experiments had not been unsuccessful, but particularly successful. He did not consider rye in his own cultivation, a very eligible crop. He could raise more of wheat than rye. The experiments of Mr Keeley, an inhabitant of Haverhill, had, however, been eminently successful.

Mr Keeley's management consisted in a sort of summer fallow; ploughing in the first and second crop of weeds on the ground, for the land was full of charlock; then sowing rye upon the ploughed furrow; and especially ploughing and sowing on the same day. This succeeded most remarkably; and on land which with ordinary management would yield not more than from ten to twelve bushels of rye per acre, he was able by his improved management, to get thirty to fifty bushels.

Mr Duncan then proceeded to speak of the cultivation of wheat. He said he laid it down as a proposition which could be demonstrated, that wheat in Massachusetts was a profitable crop; it could be raised among us to advantage; and in asserting this, he mainly relied upon his own experience. In 1822, he commenced farming. He sowed three-fourths of an acre on a ve. soil, with wheat, using one and a half bushel of seed. The yield was twenty-eight bushels to an acre. He knew nothing better with which to lay down his land to grass than wheat, and he preferred to lay his land to grass before the sword was entirely rotten or decomposed.

In 1823, he cultivated two acres of the same field with wheat; the crop was thirty bushels on one and a half acre. With the exception of a single year, he had constantly sown wheat from that time to the present; and with the exception of one year, he had always been successful in its cultivation. In the year of failure to which

allusion had been made, he had lost his own seed wheat and obtained some from a neighboring farmer; and then his crop was poor. He had been able to obtain for a series of years, from twenty to thirty bushels, without any thing peculiar or remarkable in his cultivation. The kind which he is used to plant is the Gilman (same as the Tea wheat), and the Black Sea wheat. He considered them equal in value.

He is accustomed to sow wheat on land which had been for other crops manured two years previously to the wheat. His land is usually ploughed in the fall and in the spring. He has never applied lime in any great quantity to his land; but when he could obtain that which had been broken or the rubbish of old plastering, he is glad to use it. If any lime or refuse ashes were to be got, he always endeavors to obtain them for his land. Sometimes he had applied lime to his land after the wheat has come up, and sometimes ashes. Last year he applied five to seven bushels of ashes to an acre with some success. Indeed he has always been successful in the application.

These facts should recommend the cultivation of wheat. In his opinion, no grain was so favorable to the laying down of land to grass. It would be difficult to convince him that wheat could not be successfully raised in the country. Certainly any man could raise his own bread cheaper than he can purchase it; and he considered it a sound maxim in domestic economy, that every farmer should produce as much as he can and buy as little as possible, and especially that he should grow what is required for his own consumption. He himself had raised wheat enough to supply two families for years; and at the rate of twenty bushels to an acre, no crop could be more profitable.

Another fact which came within his knowledge, confirmed his own experience. He was for some time in Essex county one of the overseers of the poor. The town was a good farm for the poor, and it is managed by a good farmer. They were in the habit of purchasing much flour for the establishment; and the bill consequently, was a heavy one. He suggested to the farmer the expediency of cultivating wheat, but the farmer said that it could not be grown on the place. Col. Duncan insisted upon it that a trial should be made. He proposed that the manager should take a bushel of seed and make a trial upon a small scale. The crop was a decent one. He tried a second crop and has continued until he raised 33 bu. to the acre; and this on land where it was said wheat would not grow. He cannot agree that it would be better to buy our flour. Let the value of money fluctuate as it may, the farmer who supplies his own wheat from his own labor and land, has a currency of fixed value, and which will not depreciate.

He proceeded to state, in answer to inquiries which were made of him, that he was accustomed to sow his wheat as early in the spring as the land could be got fit, when the land was warm and dry; and he said he prepared his seed wheat for sowing by soaking his seed in brine and then covering it with lime. He was not particular as to the quantity of lime which he used to a bushel of seed, nor as to the time during which it lay in the steep. He thought that the benefits of lime were in the prevention of smut and the destruction of insects; and that it operated likewise, as a stimulus to vegetation.

Mr Brigham, from Westboro', then proceeded to state what he had been his experience in the use of lime for wheat. It was generally understood that lime was a powerful and valuable manure. He had made several experiments during four years in the use of it upon the wheat crop, but never with any decisive results. He had sometimes sowed lime upon his land and sometimes sowed wheat without applying it, and found no perceptible difference.

One year since he prepared an acre with a view to an experiment. On one quarter of an acre he applied at the rate of 40 bu. of lime to an acre. On an adjoining quarter he applied 20 bu. per acre. On another, at the rate of 10 bushels. On the remaining quarter he applied no lime. He saw no decisive effects, either good or evil. It may be that he had not used lime in a proper manner. At any rate, he had not succeeded in ascertaining its advantages or its effects. This crop of wheat had generally averaged about 20 bushels per acre.

Another gentleman stated that he was very desirous of getting at the facts in the case, and of determining the question whether the beneficial effects of lime were as great as had been represented. He himself had not found it useful on light lands. He thinks it may be useful on clay lands in operating mechanically to divide the soil.

In 1812, the farmers at Kennebec suffered much from smut. Lime had been found effectual in destroying the seeds of smut. Other steps have been recommended

and tried, but lime is of all things the most easy to obtain. He had made many inquiries. He had asked a thousand farmers what benefits had been received from lime. But there was no satisfactory proof of any advantages derived from its use. He had been told of a farmer in Virginia who had had a great crop of wheat (a variety which had been named; but before his information through the story, he learned that the land had been richly manured). He expressed a strong wish that some persons would make in these matters such experiments as could be confidently relied on.

Mr Brigham complained in strong and just terms of imperfect manner in which experiments were made and reported. Unless they are made with great care and exactness, they decide nothing satisfactorily. Mr Brigham being inquired of as to the nature of the land on which these trials were made, answered that it was grain land. Mr B. did not doubt the utility of lime when applied to some soils, but he had not himself experienced any beneficial effects from its use.

Col. Duncan in reply to some inquiries put to him said that his soil was good and well manured. He was of opinion that a soil which was inclined to clay and strong tenacious, was most suitable to wheat. It is a practice to sow wheat on land which has been ploughed two years.

Some conversation ensued upon the use of lime in preventing smut. Mr Brigham knew a neighbor who had steeped his seed in strong brine and then coated it with lime, but the smut was not prevented.

Another farmer supposed it probable that the failure in this case arose from his not having suffered the wheat to remain at all after having been coated with lime, but his having sowed it immediately. This gentleman, speaking farther on the subject of lime, considered that it afforded no help to vegetation; that it operated to destroy nature; but that in its mechanical effects upon a tenacious soil, it might operate as sand, and serve to reduce it to a fine state.

Mr Cooley, from Hawley, Franklin county, was happy to give his experience in the raising of wheat. He had cultivated wheat for thirty years, and with as much success as any crop. He is accustomed to prepare his seed wheat as stated, with brine and lime, and allows it to remain two days before sowing. He had sown wheat (so prepared); and also allowing it to remain four days after being steeped and lined; and at the same time he had sown wheat without preparation. In the case of the prepared seed, he obtained 34 1-2 bushels to the acre; in the case of that sown dry, he obtained 19 1-4 bushels.

He tried this experiment a second time, and the result was nearly the same. He had tried three experiments of this kind. He had applied lime to his land without perceptible advantage. He considered the application of lime to the seed in general a sure preventive of smut. He thought some grounds might be infested with smut. He sowed wheat on all kinds of land. He had sown it on poor and exhausted land. For the two years past, when it had proved a most valuable crop. The land of which wheat is to be sown, should be airy; and not sheltered as to collect the damps and fogs. He, together with a neighbor of his, had had great success in the improvement of their crops by selecting their seed with great care. He had, from the selection in his field of some superior heads, obtained by cultivation a very superior variety. He himself usually selected his best seed at the planting time. It was necessary, as far as possible, to have a variety of smut, that the seed should be steeped in brine; but when lime was applied, it should remain sometime on the seed before sowing. He had obtained 15 bushels of wheat per acre on his poor land.

Mr Holland, of Maine, then addressed the meeting. He would give in this matter of preventing smut, the experience of others. In 1837-8-9, he was a joint owner of Pitt's Threshing machine; and in threshing and clearing the grain for different farmers, he inquired of them how smut might be avoided. He knew a careful farmer who had raised wheat twenty years without any smut. His rule was to steep his wheat 48 hours in strong brine and then apply two quarts of quick lime to a bushel before sowing. Other farmers whom he knew, had used blue vitriol, applying a solution of two ounces to a bushel of seed. This was considered a sure preventive, but was so beneficial to the wheat. He knew one farmer, who was accustomed to salt down his seed wheat in the winter and let it remain until time of sowing in the spring.

Mr Clark, of Northampton, stated that the farmers of his vicinity considered their wheat injured and its vegetating powers in many cases destroyed, by steeping it in strong brine. They sowed the Italian wheat and it was thought it was liable to this injury from being a thin skinned wheat.

The meeting was then adjourned to Thursday evening of this week, at the usual time and place; and it was decided that the Small Grains should be farther considered, the subject even of wheat was not exhausted, and the other grains scarcely approached.

TO READERS AND CORRESPONDENTS.—We have received the Reports of the Plymouth Co. Agricultural Society, and others of the Massachusetts Society, which if he laid early before our readers. A large space is occupied to-day with the Memorial of the Commissioner, it was desirable to give it at one time; and to give it so, as otherwise it would be no better than last year's manac. We invite the attention of the farmers to it.

The communications of Mr Howard and W. B. shall appear as soon as space can be devoted to them.

MASS. HORTICULTURAL SOCIETY.

A stated meeting will be held at the Rooms of the Society, No. 23 Tremont Row, on Saturday next, the 7th of March, at 11 o'clock, A. M.

E. M. RICHARDS, Rec. Sec'ry.

March 4, 1840.

FRUIT TREES.—Those who intend to set out fruit ornamental trees this spring, can have no better time than the present, to take them from the nurseries in the city of Boston, as the ground is entirely free from frost, favorable an opportunity to send them to a distance has occurred for years before, as they may now be forwarded to any part of the country before warm weather commences. Orders forwarded to Joseph Breck & Co. will receive prompt attention.

BRIGHTON MARKET.—Monday, March 2, 1840. Reported for the New England Farmer. Beef Cattle, 10 pairs Working do, 18 Cows and Calves, and 500 Sheep.

Prices.—Beef Cattle.—Last week's prices were falsitained but without much improvement. A few were taken at \$7 00. First quality, \$6 75. Second quality, \$6 25 a \$6 50. Third quality, \$5 25 a \$5 75.

Working Oxen.—No sales were noticed. Cows and Calves.—"Dull" A few sales only were noticed. \$23, \$30, \$38, and \$40.

Sheep.—Lots were sold at \$2 50, \$3 00, \$3 75, \$4 50, \$5 00.

Pigs.—None at market.

THERMOMETRICAL.

Reported for the New England Farmer. Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded northerly exposure, week ending March 1.

Table with 5 columns: Date, 7 A.M., 12 M., 5 P.M., Wind. Rows for Feb. 24, 25, 26, 27, 28, 29, 30, 31.

Orchard and Vegetable Garden, and Mowing Land. Two Miles from the City. To be Leased.

Two subscribers offer to let on a lease of two or more acres of land situated in Dorchester, (about two miles distant from the Old South Church, Boston,) belonging to Z. B. Jr. There is a garden on the premises of about 23 acres having a southern aspect; well filled with fruit trees of every kind. The land is rich and strong, and can be made to yield early and abundant crops, and from its vicinity to the Boston Market, offers the greatest inducement. The remainder of the upland is now laid down to grass, of which it yields abundantly, and there are several acres of cranberry immediately adjoining. A large and convenient barn is also upon the ground. The above will be let upon the most favorable terms, on application to COOK & COFFIN, No. 65 Commercial Wharf.

ROHAN POTATOES.

For sale by S. LOTHROP, West Springfield, Feb 4.

PEAR, PLUM, GRAPE VINES, &c.

2,000 Pear Trees, of the most approved kinds. 1,000 Plum Trees, of the most approved kinds and extra size—many of them have borne the past season 500 Quince Trees. 3,000 Isabella and Catawba Grape Vines, from 6 to 15 feet high, most of them have borne fruit—Black Hamburg, Sweetwater, Pond's Seedling. 30,000 Giant Asparagus Roots. 5,000 Wilmot's Early Rhubarb or Pie Plant, lately introduced.

Also a good assortment of Gooseberries, Roses, &c. of different kinds. All orders left at this office, and at Gould & Howe's Iron Store, Faneuil Hall or with the subscriber at Cambridgeport, will meet with immediate attention.

SAMUEL POND, Cambridgeport, Mass.

WINSHIP'S NURSERIES, BRIGHTON, MASS.

The proprietors of this Nursery are now ready to receive orders for their extensive assortment of Fruit and Ornamental Trees, Forst Trees, Shrubs, Herbaceous Plants, Roses, Green House Plants, Vines, &c. Orders from a distance will be properly packed to go with safety to any part of the United States, and will be delivered in the city free of expense.

The Nursery grounds are five and a half miles from the city, by the Worcester Rail Road; cars stop three times a day. Orders by mail addressed to Messrs. WINSHIP, Brighton, Mass., will be promptly attended to.

WHOLESALE PRICES CURRENT. CORRECTED WITH GREAT CARE, WEEKLY.

Large table listing various commodities and their prices. Columns include item name, unit, and price. Items include Alum, Ashes, Beans, Beef, Butter, Candles, Cheese, Eggs, Flour, Hides, Lard, Oil, Soap, Tallow, Wool, etc.

PRATE AND POUZRETTE.

The Company known in the City of New York by the name of "THE NEW YORK URBAN VEGETABLE COMPANY" has been incorporated in the Legislature of the State of New Jersey, in an Act, entitled "An Act to Incorporate 'THE LOUI MANUFACTURING COMPANY,' for purposes of Agriculture—with a Capital of 2000 Shares, each Share \$100, being equal to a Capital of \$200,000.

A Pamphlet has been published containing particulars and very important information to Farmers and Gardeners, a Copy of which may be seen at this Office, or procured from A. Dey, No. 71, Cedar st., New York.

The particular attention of the reader is requested to the following particulars:

1st. A Subscription for a part of the Stock of "THE LOUI MANUFACTURING COMPANY," will be open at the house of Messrs. Miller, Keeper of the Eagle Hotel, in the City, opposite the City of New York, on Wednesday and Thursday, the 5th and 9th days of April, 1840, from 10 o'clock in the forenoon until 2 o'clock in the afternoon of each day, and the payment of \$25 on each Share will be required to be paid at the time of subscribing, (either in Specie, or in Bank Bills of the Specie-paying Banks.)—See Section No. 4 of the Act of Incorporation.

It may be, if the whole 1500 Shares shall be subscribed for, that nothing more than the \$25 may be called in upon this Stock; but if any person chooses to pay the whole amount, he will draw dividends accordingly.

2d. If 500 Shares shall be subscribed for, on the 5th and 9th days of April, 1840, and if no more subscription they will be, the further subscription of 500 Shares by Farmer and Gardeners exclusively, will be opened at the Office of D. Y. & Elmendorf, No. 71, Cedar street, in the City of New York, and be continued open 60 days, commencing on Monday the 13th April, 1840, from 10 o'clock in the forenoon until 2 o'clock in the afternoon of each week day, and continuing open until the 20th day of June inclusive, or until the whole of the said 500 Shares shall be subscribed for, so long as these 500 Shares shall be subscribed for, the books will be closed. The Dividend on these 500 Shares is to be 50 bushels of Potondeite to each Share, for 3 years, which is equal to 20 per cent. per annum, so that at the end of 3 years they will have received back their whole money.—See Section No. 6.

The object of the Company in procuring Stockholders is to procure consumers, and therefore they prefer Farmers and Gardeners to subscribe one Share of the reserved Stock, rather than five Shares to which each is entitled, and it is well ascertained that 500 Shares of the Stock of the Company will be sold at equally valuable prices, than there is any quantity given by law to the Company to guarantee that 20 per cent shall be paid in Potondeite. It is expected that the Dividends on this reserved Stock will be made, half in May and half in September, in each year, and therefore the whole amount of the reserved Stock, say \$100 each Share, must be paid for at the time of subscribing.

3d. Persons disposed to subscribe, may authorize any person to do so for them as follows:

"I, of the Town of in the County of and State of Farmer, (or Gardener as the case may be,) do hereby authorize to act in my name for the purchase of Shares of the Stock of the Loui Manufacturing Company, and to receive the monies required to be paid at the time of subscription.

Witness my hand this day of 1840.

WITNESS PRESENT,

The subscribers are not held responsible to pay any thing beyond the payment required at the time of subscribing.

Any number of Farmers in one neighborhood may authorize any one of their number or any other person to subscribe for them.

4th. AGENTS.—A number of Persons have already been appointed as Agents in different parts of the United States. The Company allow Agents a commission of 8 per cent for their trouble, on the net amount of the cost of the Potondeite to the Station of the Act, Farmers and Gardeners exclusively are secured the preference, and the monies equal to \$45,000 over any other consumers. They are secured an annual dividend of 50 Bushels of Potondeite for every 100 dollars they invest in the reserved 500 shares of the Stock of the Company, which at the price the Company have sold and offered for the monies, gives a dividend of 20 per cent. per annum for 3 years, and if no more subscription they will be the other Stockholders. It is believed, however, from data which have been furnished by a pamphlet, that the dividends on all the stock will not be less than 20 per cent. per annum.

One cent's worth, under the provision of the 6th Section, will manure 10 hills of corn. One half of Potondeite to each hill will cost in 1840, 1 cent, and if the corn is raised the time it was planted, so far as to render it too hard to eat as green corn, which would save us from destructive effects of an early frost.

But one of the greatest advantages that Potondeite has over every other manure, is the saving of labor in its transportation to the farm, and its application to the soil. The saving is one half in the amount of cost, labor and expenses attending the same.

Any Farmer in moderate circumstances who loans his money at 6 per cent. interest per annum, may take one share

of the stock of the Company which would cost him \$100, and receive a dividend of 50 Bushels of Potondeite which would cost him 12 cent. per Bushel, and will do his land and crop more good than 50 loads of the best horse manure, that would cost him \$50 besides the labor and expense of carting and putting it on the land.

If any person wishes further information on the subject, they will apply to ANTHONY DEY, either in person or by Letter directed to him at his office, No 71 Cedar street, New York.

STRAWBERRIES.

Those who are desirous of cultivating this delicious fruit are respectfully informed that the subscriber has succeeded, after a number of years experimenting upon the *Strawberry*, not only in obtaining new varieties, but in ascertaining the best method of cultivation.

Specimens of the fruit grown in his Garden have been exhibited at the Massachusetts Horticultural Society Rooms, the four past years, and are also too well known in *Pluralist Hall*, to need particular notice here.

He has for sale at his Garden, in Brighton, Mass., the following eight varieties of Plants. They are of superior stock and quality, all warranted to be truly named and free from the *injuries* often found in those offered for sale promiscuously.

Those who are in want of Strawberry Plants, are respectfully invited, and they will find it interesting, to call at the Garden and see the manner of cultivation. The method of cultivation, and any information desired will be cheerfully given.

Harrow's Seedling Methuen.—A new and valuable kind. A free bearer, fruit very large and juicy; fruit measuring four and a half inches have been exhibited the past season.

Methuen Seedling.—Fruit extremely large, high flavored, and showy. Specimens of this kind have been exhibited at the Horticultural Rooms for two years past, measuring five and a half inches in circumference.

Bath Seedling.—Fruit large, full bearer, and beautiful scarlet.

Early Virginia.—This is considered the earliest fruit—a free bearer, hardy, and very early; decidedly a fine kind for market.

Royal Scarlet.—Fruit long oval shaped and juicy.

Hautbois.—Fruit smaller but very numerous.

English Wood.—Fruit well known.

Monthly.—Fruit is gathered from the vines from June to October, and in good quantity and fine quality.

Orders left at the Garden, or directed to the subscriber, Brighton, Mass., or left at Messrs. J. Breck & Co.'s Agricultural Warehouse, Boston, will be carefully and promptly attended to, and all Plants will be carefully packed and forwarded agreeably to directions.

JAMES L. F. WARREN.
Nonantum Vale, Brighton, Mass., March 4.

BONE MANURE.

The substance informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone, and the manure of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 49 cents per bushel, and no charge for casks or carting.

Also, Oyster Shell Lime, price 19 cents per bushel at the kiln; put up in casks four bushels each at 60 cents per cask delivered at any part of the city, and Ground Oyster Shells.

Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 62 North Market Street, or through the Post Office will meet with prompt attention.

March 4, 1840. NAHUM WARD.

Fruit and Ornamental Trees, Mulberries, &c.

Fruit Trees of all the different species, of the most celebrated and surpassing kinds; the collection now offered is large. The Catalogue of Fruit and Ornamental Trees and Shrubs, Roses and Herbaceous Flowering Plants, for 1839, is now ready and will be sent to all who apply. In that catalogue the very best kinds of Fruit, so far as proved, are particularly designated by a *.

100,000 Morgan Mulberries, or any other reasonable quantity, or Cuttings of the same, are now offered for sale. The trees are genuine, all being raised by the subscriber, either at his Nursery here or at his Southern Establishment at Portsmouth in Lower Virginia. Also, the Elata, Conton, Moretti or Alpine, Brucensis, and some other Mallieris, Creek, and Buckthorns for hedges, &c.

All orders shall be promptly attended to, and trees will be securely packed for distant places.

WILLIAM KENRICK.
Nonantum Hill, Newton, March 4, 1840.

FARMS FOR SALE.

For sale, a farm in a high state of cultivation, situated in the southerly part of Needham, bordering on Charles River, pleasantly situated, and within one quarter of a mile of Needham and Dover Mills, and within six miles of Dedham Court House, containing about 55 acres of land suitably divided into tillage and pasturing; well watered, and mostly fenced with good stone walls.

There is a young orchard containing about 150 choice Fruit Trees in a flourishing state; a large and convenient dwelling house; a new Barn 40 by 60 feet, with a store and Granary connected with it, and cellar under the whole, with a first rate piggery. If said farm is not sold by the first of April next, the house and store will be let. The store is convenient and well situated for trade.

Also—a small farm situated in the northerly part of Dorer, and within half a mile of the above named mills; a desirable situation for a mechanic, containing about 30 acres of land, and well watered; with house, barn, and out-buildings.

The stock and all farming utensils of the said farm will be sold at public auction on Wednesday, 15th March.

For further particulars inquire of LEONARD BATTLE, in Needham, near said farms, or CALVIN FRENCH, on the premises.

Needham, Feb. 26, 1840. 4w

FARM FOR SALE.

For sale, a superior farm of nearly fifty acres, between Boston and Lowell, 15 miles from the former place; on which is situated a convenient dwelling house, barn, and other buildings in good repair, and an orchard of choice fruit trees. For further particulars inquire of the subscribers, No. 32 North Market Street. JOSEPH BRECK & CO.

February 26. 6w

TO FARMERS.

600 casks Lime of good quality, for sale by the subscribers at their wharf Front Street.

We would remind consumers of this article that the casks are large and have at least one fourth more in quantity than in former years. Price 112 cents per cask.

CARTER & WILLARD.
February 26. 4w

SCIONS OF FRUIT TREES FOR SALE.

The collection of fruits cultivated at the Pomological Garden consists of more than 1400 varieties of the Apple, Pear, Plum, Cherry and Peach. Scions of all those which have been proved are offered to nurserymen and others. Gentlemen wishing to send collections of American fruits to their friends in Europe can be furnished with most of those of first rate quality. They are warranted true to their names, and are in all cases cut from fruit bearing trees.

Salem, January 28, 1840. ROBERT MANNING.

FLOWER SEEDS—CHOICE VARIETIES.

JOSEPH BRECK & CO. have received a choice assortment of Flower Seeds from England and France, which, in addition to what have been raised under their own supervision, embrace the finest collection to be found in the country, including all the new Annuals, Biennials, and Perennials worthy of cultivation; neatly done up in papers at 6 1/4, 12 1/2, and 25 cents each. For sale at 51 and 62 North Market Street.

February 5.

ROHAN POTATOES.

For sale at the New England Agricultural Warehouse and Seed Store, No. 62 North Market Street, at \$5 per barrel.

October 15. JOSEPH BRECK & CO.

GARDENER WANTED.

Wanted, a Gardener of steady habits, that understands raising vegetables and taking care of fruit trees. An American, with a small family, would be preferred. None need apply without good recommendations.

February 19.

GARDEN MATS.

For sale at the New England Farmer, 100 dozen Garden Mats, of extra quality, for covering hot beds, &c.

Feb. 12. JOSEPH BRECK & CO.

THE NEW ENGLAND FARMER

Is published every Wednesday Evening, at \$3 per annum payable at the end of the year—but those who pay with sixty days from the time of subscribing are entitled to a reduction of 50 cents.

BOSTON, WEDNESDAY EVENING, MARCH 11, 1840.

[NO. 36.]

N. E. FARMER.

We have the pleasure of giving to our readers below, the speech of Gen. H. A. S. Dearborn at the seventh Agricultural meeting, and do not doubt our friends will have much pleasure in its perusal. We have reported it as well as we could from our imperfect notes and imperfect recollections, but we hope we have not failed to present its substantial features.

H. C.

SPEECH OF GEN. H. A. S. DEARBORN,

At the Seventh Agricultural Meeting, Feb. 28, 1840.

He began with expressing his diffidence in appearing on such an occasion, and addressing so respectable an assembly of intelligent and practical men. He felt likewise the disadvantages under which he labored in succeeding such men as had on former occasions addressed them; men eminent in the walks of science, and distinguished by their particular and most successful application to sciences of a profound character, but which had an immediate connexion with agriculture. Chemistry and Geology, as well as the branches of vegetable physiology, were intimately associated with agriculture: and on these topics they had the high ratification of hearing from some of the most distinguished men in the country.

They had likewise been addressed by that eminent statesman, who is the just pride of the commonwealth and of the nation, who had recently returned from Europe, like Anacharsis from Greece, to enrich his country with the treasures of wisdom which he had been gathering in foreign countries—the Athens and Byzantium of modern Europe.

But however much these considerations might weigh with him, yet they did not allow him to refuse any contribution which he might be thought capable of rendering to a cause which he deemed so important, and which had so deep hold upon his affections, as an improved agriculture. Others had entered the field before him and gathered the abundance of the harvest; he would come as a mere gleaner, satisfied if he could bring with him but a single sheaf.

It is a common remark that agriculture has not advanced with a rapidity equal to that which his other arts had gone forward. Under the circumstances of the case, it was not to him so much matter of surprise that agriculture had not gone farther, as that it had gone so far.

New England was settled under peculiar circumstances. The departure of the pilgrims from England differed from the Exodus of the Israelites, in that when the latter left Egypt they went into a country highly cultivated, after their journeyings in the wilderness were over, and in a climate highly favorable to comfort and industry; but the pilgrim fathers came into a country wholly barbarous and uncultivated; into a climate perilous and severe; and to a scene of extraordinary and accumulated hardships, and where the great struggle to be had was a struggle for existence.

The colonies sent out by the Greeks and Romans, went out for purposes of conquest. In most cases they went among a people already advanced in the improvements and arts of life, and the transition was little more than a change of place and property. The Romans penetrated into Germany, Gaul, and Britain merely for purposes of conquest, and left colonies only in Gaul. Their colonies were an oppressed and conquered people; but they were the inhabitants of a country already cultivated and improved.

The settlement of New England is an anomaly in the history of civilization. The pilgrim fathers entered into a wilderness not preceded by an army to open their way; nor protected in their settlement by a military force; but where all were called upon to rely upon their personal virtues and energies—their muscular strength, their industry, their economy, their trust in a divine Providence. This was their protection and their capital.

The whole country was to be conquered by labor. There were no bright spots of cultivation and improvement to cheer the prospect. They had no wealth to invest in improvements. Each man had to struggle hard for a subsistence from day to day for himself and his children. They must do this or perish. They did indeed by the blessing of God surmount these great obstacles; but that under such circumstances agriculture should not have advanced here as it did in other countries, abounding in wealth and advanced in the arts of improved life, is not matter of just surprise. The art of agriculture, though first in importance, seems to have been the last to reach a high degree of improvement in any country.

In the beginning and in the first steps in the progress of society, men from barbarism passed into the nomadic state, and became herdsmen and shepherds. This was the condition of the patriarchs. It is still the condition of the Arabs. Tartary, from the Euxine sea to the walls of China, is still in the same condition. The traveller Clark says the Calmuc Tartars as they were in the days of Herodotus, still live in tents, tending their flocks and herds, and do not till the earth. The ancient Greeks and Romans were absorbed in commerce, in the mechanic arts, in the arts of ornament, in literature, poetry and eloquence. These had made great advances before agriculture was justly appreciated. Rome was devoted to military conquest and glory, and had become the mistress of the world, before any due honors were paid to the noble art of agriculture. There were indeed distinguished men, who as is common to distinguished minds, had a just taste for rural occupations, scenes and pleasures. Cicero and Lucullus, Tacitus and Seneca had their charming villas, to which they were delighted to retire from the noise and bustle of the capital.

The philosopher Seneca, at his country seat of Nonentannum, and in the midst of his groves, received the sentence of death. His life presents an example which will continue to guide and stimulate men to virtue, when the memory of the infamous tyrant who ordered his death, will perish in

oblivion or be remembered only to be execrated.—Tacitus wrote his history in the country; and there he composed the biography of his father-in-law, Agricola.

Agriculture at length rose in the estimation of the distinguished Romans. The Senate patronised the rural arts. Cincinnatus was taken from the plough. Cato wrote a book upon agriculture. The Georgics of Virgil and the writings of Columella are rich in the science of husbandry and rural cultivation. The Carthaginians wrote several works on agriculture. But it had not even then attained to its just rank.

In France and Italy other arts preceded this great art, and it remained far in the rear. Until the reign of Elizabeth, agriculture had been greatly neglected in England. The vegetable products of the soil were very few; and their tables were most scantily supplied. They were before her time dependent upon other countries for bread. Yet England was better cultivated than any country upon the globe, excepting some parts of China.

But England has made rapid and extraordinary advances in this useful and beautiful art, and now, in her cultivation, presents an example of all that is exact and careful in cultivation, useful in productions, and charming and tasteful in embellishments. We are the descendants of England; yet in some things we have at least in these matters reversed the order of sentiment which prevails with them.

In England, the pleasures and privileges and blessings of the country seem properly understood and valued. No man there considers himself a freeman unless he has a right in the soil. Merchants, bankers, citizens, and men of every description, whose condition in life allows them to aspire after any thing better, are looking forward always to retirement in the country, to the possession of a garden or a farm; and to the delicious enjoyment of rural pleasures. The taste of the nobility of England is all this way. There are none of them, who with all the means of luxury which the most enormous wealth can afford, ever think of spending the year in London, or of remaining in the confinement, noise and confusion of the city, a day longer than they are compelled to do by public duty or imperious necessity.

There is, in this respect, a marked difference between England and France. Formerly, in France, the nobility were scattered broadcast over the territory, and had their villas, their castles and chateaux in all the provinces. But the monarchs, anxious to increase the splendor of their courts and to concentrate around them all that was improved and beautiful in fashion, luxury and wealth, collected the aristocracy in cities. The natural consequence was that the country was badly tilled, and an improved agriculture made no advances.

Spain was formerly the granary of Europe. The great means of enriching land, irrigation, was practised there to a great extent; and manuscripts of great antiquity now to be found in the libraries of their princes, show that the knowledge as well as the practice of the art, had made great progress.

The discovery of silver and gold mines in the south, the curse of an ignorant priesthood, and a despotic and rapacious government, had proved fatal in Spain to the prosperity of agriculture.

Happy would it be for us if our men of wealth and intelligence would copy the bright example of the gentlemen of England. If our men of wealth after having accumulated immense fortunes in cities, would carry their wealth and science into the country, and seek to reclaim, to improve, to render it productive, and to embellish it, Massachusetts might be transformed into a garden, and rival the best cultivated districts in the world.

It is an inexplicable fact that even men who have grown rich by trade or other means in the country, should rush into the city to spend their wealth. It is as inexplicable that men who grow rich in the city, should shudder at the idea of going into the country, where wealth might be safely and securely appropriated to purposes of the highest utility, pleasure and taste.

There prevails in this matter a great deal of false sentiment and of ignorant and unworthy prejudice. These men anxiously inquire if they go into the country, how they shall pass their time; and what is to relieve the solitariness and tedium of their evenings? To the active and intelligent farmer living in the country, and actively engaged in rural labors and improvements, during the season of vegetation no day is long enough for labor; and in winter no evening is long enough for domestic pleasures, and intellectual cultivation and the pursuits of science.

If the rich were not swallowed up in avarice and that narrowness and selfishness which the pursuit of money too often creates and too strongly natures, they would find a liberal and delicious satisfaction in cultivating and embellishing a farm, in multiplying the productions of the soil, in introducing the fruits of warm climates and in protecting and naturalizing them here, and encouraging useful labor and promoting by the liberal reward of industry, the comforts of many around them.

Every one knows that the retirement and quiet of the country are favorable to the cultivation of science. Astronomy is best studied in the country, and in the clear sky and open horizon, men become familiar with the aspects of the stars as with the faces of valued friends. They see in the heavens, in the influence of the natural agents above and around them, in all the progress and stages of vegetation, and in the multiplied forms of animal and vegetable life, continued and instructive proofs of the universal and unwearied agency of the great Husbandman. Geology, mineralogy, chemistry, botany, and all the natural sciences are pursued with peculiar advantage in the country.

An important branch of natural philosophy, the science of hydraulics, may be pursued to great advantage, and bears directly and most essentially upon agricultural improvement. Irrigation is one of the most important means of enriching land and rendering it productive. Damascus was celebrated for its fields and gardens as well as for its commerce. The fertility of Damascus was created by artificial irrigation. A traveller found a stream from the mountains which, by artificial canals, was spread over the land. Wherever this water came, vegetation exhibited its luxuriance. So distinctly marked were the limits of improvement, that you could stand with one foot on a highly cultivated and productive territory, while the other rested upon a barren sand. All these extraordinary improve-

ments came from irrigation. It was so with all the countries bordering on the Euphrates. It was so in Egypt, excepting the Delta, which was enriched by the overflowings of the Nile.

As population multiplied in Egypt, it became necessary by artificial irrigation, to increase its productiveness. The canal of Joseph has been the subject of ancient tradition, and is supposed to have been made for purposes of irrigation when he was governor of Egypt. The waters were drawn off in the higher parts of Egypt and were used for the enriching of the land. This it was that made Egypt the granary of the world.

In Spain the agriculture is miserable. Yet the canal of Zaragoza, which was dug to open a communication between the Bay of Biscay and the Mediterranean, was designed likewise for the irrigation of the country. The experiment here was so successful that a canal sixty miles in length has watered a surface of thousands and thousands of acres, which have thus been rendered productive in wheat. The revenue paid by the farmers to the government for the use of this water, is equal to 25,000 dollars per year. In many places fountains are erected and reservoirs opened, by which the water is spread by various channels over a large territory.

Such operations as these, when pursued even on a small scale, must prove a source of rich gratification to a cultivated mind. The country is friendly to the cultivation of all the beautiful and the useful arts, for here all find their place and use. In the erection of his buildings, some skill in architecture in respect to their strength, their comfort, their endurance, and their convenience is necessary, and the humblest erection on a farm may be made a pleasing object, when framed and fashioned by a cultivated taste. For all the mechanical arts, both the science and the practice, there is on the farm an almost daily use and demand.

The country is favorable to the cultivation of literature and general science. Persons not familiar with the subject are not aware how large and interesting a library might be formed of books exclusively devoted to agriculture and its twin sister, horticulture. These sciences are adorned likewise with the brightest names which shine in the annals of knowledge—those of Bacon and DuRoi. The former sought to interest his countrymen in rural labors and pleasures. The latter, a man of kindred mind, has given to the world the best work on trees and other subjects of agricultural improvement, which is extant.

There is a constant demand in the country for mechanical skill, and the exercise of the most cultivated taste in the laying out and establishment of grounds, in the forming of roads, in the planting of trees, in the conducting of water, and in the countless circumstances of ornament or utility, which to a mind bent upon useful occupation, constantly present themselves.

Ornithology is a study which can only find its true home in the country. Who would not wish to become acquainted with the birds that cluster around his habitation, and make their home in his groves and gardens, and welcome him with their cheerful notes, and charm him with their melodious morning and evening hymns of praise? Who would not wish to live among them as friends; and to understand their habits and gather instruction from their beautiful examples of domestic affection and duty? Natural history in all its branches is a proper study for the country. Not an insect visits

the territory of the farmer but he should learn its character and habits. Some are his enemies. Some of these, the bee and the silkworm, are eminent for their friends and benefactors.

The silk-worm by his industry furnishes a large portion of the clothing of mankind. Take the civilized population of our whole country, and there scarcely a man, woman or a child whose dress has not received some contribution from the labors of this humble operative.

Gen. Dearborn continued by saying that he had barely alluded to these subjects for the sake of showing that there is every thing in the country to call into healthful exercise the physical and the intellectual powers of man; a bounteous table there spread; and there is rich and abundant food for the body and the mind.

The city must, of course, be regarded as the proper seat of active business and commercial life. But when a large portion of life has been spent in these harassing pursuits, and men have accumulated the means of competence and independence in the country, why they should not seek to enjoy refreshing labors, its delightful recreations, and avail themselves of its privileged hours of retirement and reflection, was to him a mystery which he attempted in vain to solve.

For himself he could say, with the exception of three years spent in Washington, which then indeed could hardly be called a city, excepting one traveller denominated it, a city of magnificent distances, his home had always been in the country. There he had found his most agreeable labors and his richest pleasures, and the progress of time had served only to strengthen and rivet his attachments to rural life and scenes. He had sometimes been compelled to visit cities in which he was stranger, and there he had often felt a desolation of heart like that of Marius sitting on the ruins of Carthage.

The return even to a forest, which was the scene of his childhood sports and visits, was like the meeting again of old friends;—in the trees which he remembers having often seen, and in the birds, which seemed in their cheerful notes and quiet approach to bid him welcome. In visiting a city he has often felt like the noble-hearted Jennie Deans, who when she went up to London to obtain the pardon of the Queen for her misguided sister, passed the night with her cousin who kept a snuff shop and was a dealer in Scotch snuff. The simple girl wondered that for such a residence and occupation her cousin was contented to leave "the bonnie green braes of her own land."

It was not merely the unfavorable influence of city life, as he so considered it, upon health, comfort and enjoyment; but he had often deplored its pernicious moral influences. Many an uncorrupted young man from the country, impelled by the insatiable and too often reckless passion for gain has there early found the grave of his virtue. But too many instances might be pointed out in which the acquisition of property has proved as great a curse as could befall them. The chances of trade are likewise much more numerous and uncertain than men believe or are willing to allow. After pretty extensive acquaintance with business men and no limited observation of the common course of things, he was satisfied that among one hundred merchants and tradesmen, not more than three in the city ever acquire independence. It was with great distrust that he came to this conclusion, but upon consultation with an experienced merchant

fully admitted its truth. The dangers to virtue a city are very great, as is well known; and infinitely better would it be for a vast portion of the young and the old to crowd from the country into the city, if they could be satisfied with a farmer's life. How preferable would it have been for many of those who have sought wealth and distinction in cities, if they had been satisfied with the comforts, innocent amusements and soothing quietude of the country; and instead of the sad tale of their dissasters, which must go back to the parental fireside, the future rural bard as he passed the sequestered and humble church-yard, in which they had been laid at rest, with their laborious ancestors, might say—

"Some village Hampden, that with dauntless breast,
The little tyrant of his fields withstood;
Some uninjured Milton here may rest;
Some Cromwell, guiltless of his country's blood."

Infinitely better would it be for them to pass their lives in the deepest obscurity of the country, than risk, as is too often done, all their peace and honor in the perils and adventures of a city life.

He was not unaware that these things were in many respects purely matters of taste. He knew full well that a country residence could not be alike pleasant to all; but for himself he could say with truth that the humblest cottage in the country would be better than the most magnificent residence in the city. It was a source of consolation to his minds inspired with rural taste and attachments, that they should at last find a peaceful grave in some sequestered vale, under the shade of trees planted by their own hands.

He congratulated the farmers of Massachusetts on the impulse which was given to agricultural inquiry and improvement throughout the State and the whole country. The encouragement given to agricultural science and improvement was a like object of congratulation. These subjects were now reflecting and concentrating the intelligence and the best of the brightest and most improved minds, and it could not fail to give them a generous and lasting impulse.

The great name, the honor and boast of our country and mankind, adorns the pages of agricultural history. Washington was distinguished for his agricultural taste, for the interest which he took in the cultivation of his farm; and for the eminent improvements of which he was instrumental. He referred particularly to his having taken the lead in the importation of several of the most valuable breeds of cattle, sheep and swine for the improvement of the livestock of the country, one of the most important and valuable objects to which the attention of the farmers could be directed. He never forgot his farm even in the midst of his public engagements and services; and his journals, which are published, show in the very midst of his public cares, the most exact and particular arrangements and directions given to his manager for the conduct of his farm and the improvement of his grounds. This his correspondence with the most eminent agriculturists of Europe shows in a like manner.

This generous impulse has gone forth. Archibedes said in his enthusiasm, if you would give him a place on which to stand, he would move the world. We have found a place in a free country, where the mind is free and the body is free to effect any improvement within the capacity of man, and by which the human race may be benefited. A voice was heard among the mountains of Ger-

many which, in proclaiming liberty every where within hearing, aroused the minds of men to powerful action. In this new world, a voice went forth in the thundering cannon of Bunker Hill, which announced freedom and independence to the country. This great revolution opened a wide field for enterprise; awakened into extraordinary activity the powers of the mind; gave birth as it were, to industry; kindled every where the fires of science; and stretches out before the ambition of patriotic and intelligent minds, an interminable course of improvement. Much has already been done for the great cause of education and the improvement and elevation of the laboring classes, the great sources of wealth and the true foundation of independence to a country. The mysteries of science, under our free institutions, are unlocked to them; and mechanics are found, not blind machines, like those which come out of their own work-shops, but capable of teaching even from the chain of philosophy, the profound principles of their own art; that what was once merely an art is now elevated to a science.

A new and most powerful agent has been enlisted in the service of man and promises the most extraordinary benefits to art and science. Our sailors aided by this mighty power, traverse the ocean as if Neptune himself stood at the helm. The chariots of fire course over the land; and lightning and magnetism will, ere long, be yoked to the triumphal car of genius. So rapid is the progress of intelligence, that the anticipations of the most imaginative are likely to be fully realized.

Facts now are the great objects of pursuit. Theories are not likely to be received unless established by facts and experiment. Truth and utility are indissolubly allied. That knowledge is mainly valuable which can be applied directly to purposes of usefulness. The prospect of benefiting our fellow men should give activity and energy to all our powers and labors. In the progress of improvement and the benefits of science, it cannot be doubted that agriculture, the art of arts, allied so closely and inseparably with the most important physical, political, social, and moral interests of mankind, will not and cannot be denied her full share. Improvements here must mainly rest upon facts. Every improvement in agriculture established on facts, cannot fail to be most extensively and permanently beneficial. Let us labor in this great cause with intelligence and zeal, persuaded that no pursuit is more innocent and honest; no engagement to a virtuous and inquisitive mind more engaging and satisfactory; no labor more certainly useful to the community; and none which has or can have a more favorable and beneficent influence upon individual comfort, upon private morals, and upon the general welfare.

RELIGION.—Take away religion and you take away the foundation of much that is noble and exalted in man. He who possesses it, looks upon the world with an increase of admiration; he feels himself glowing with a renovated love to his fellow creatures—and at once acknowledges the invisible and all-pervading power of the Eternal.—Religion throws a brilliancy upon the morning of life; it embellishes the gay and fanciful dreams of childhood; it falls like a refreshing dew upon the hearts of the young and innocent, softening the feelings and affections, without their knowing whence it proceeds.
—Abbott.

MASS. HORTICULTURAL SOCIETY.

A meeting of the "Committee on Flowers," of the Mass. Horticultural Society, was held at the room of the Society, in Tremont Row, on Saturday, Jan. 25, 1840.

The business of the meeting having been stated, it was moved that Mr C. M. Hovey be appointed Secretary. The committee then proceeded to declare the premiums offered by the Society, for 1839. They were as follows:

- Geraniums.**—For the best 12 varieties, to W. Meller, a premium of \$10,00
- For the 2d best 12 varieties, to Hovey & Co., a premium of 5,00
- Tulips.**—For the best 12 varieties, to S. Walker, a premium of 10,00
- For the 2d best 12 varieties, to S. Walker, a premium of 5,00
- Roses.**—For the best display of flowers to A. Aspinwall, a premium of 10,00
- For the best 24 varieties, to S. R. Johnson, a premium of 5,00
- For the best 12 varieties, to R. Howe a premium of 3,00
- For the best 12 Chinese and other tender varieties, to S. R. Johnson, a premium of 5,00
- Pinks.**—For the best display of flowers, to S. Walker, a premium of 5,00
- For the best 6 varieties to S. Walker, a premium of 3,00
- For the best seedling, to W. Meller, a premium of 3,00
- Carnations.**—For the best display of flowers, to Messrs Mason, a premium of 5,00
- For the best 6 flowers, to W. Meller a premium of 3,00
- For the best seedling, to W. Meller, a premium of 3,00
- Violas.**—For the best display of flowers, to S. Walker, a premium of 5,00
- For the 2d best display, to S. Walker, a premium of 2,00
- For the best seedling, to S. Walker, a premium of 3,00
- Dahlia.**—For the best display of blooms, to M. P. Wilder, a premium of 10,00
- For the 2d best do., to J. J. Low a premium of 8,00
- For the 3d best do., to Joseph Breck & Co., a premium of 7,00
- For the 4th best do., to Hovey & Co., a premium of 6,00
- For the 5th best do., to S. Walker, a premium of 5,00
- For the 6th best do., to Messrs Mason, a premium of 4,00

Total amount of premiums \$125,00

The committee also awarded the following premiums, in addition to the same sums, offered by the liberality of T. Lee, Esq., for the encouragement of the growth of the most ornamental species and varieties of native flowers, viz:—

- For the best display of Native flowers through the season, to William Oakes, Esq. of Ipswich, a premium of \$5,00
- For the 2d best display of the same, to E. Weston, Jr. Esq., a premium of 5,00

No competition was thought deserving of the 3d prize, and the committee reserved the balance, appropriated for 1839, to be added to that of 1840.

A committee of three, from the flower committee, was then appointed to draft rules and regulations for the exhibitions the ensuing season, and instructed to report on or before the second Saturday in March. The following gentlemen were chosen that committee, viz: J. E. Teschemacher, C. M. Hovey, D. Haggerston.

The meeting was then adjourned.

All of which is respectfully submitted,
per order

S. WALKER, *Chairman.*

Attest, C. M. HOVEY, *Sec.*

Approved by the Executive Committee.

Report of the Committee for awarding Premiums on Fruits, &c.

The Committee on Fruits, &c., of the Massachusetts Horticultural Society, have attended to the subject of Premiums for the past year, and have awarded them as follows:

<i>Pears.</i> —For the best Summer Pears, to Mr Samuel Pond, a premium of	\$5.00
For the best Autumn Pears, to Mr Richard Ward, a premium of	5.00
For the best Winter Pears, to Mr E. Vose, President of the Society, a premium of	5.00
<i>Apples.</i> —For the best Summer Apples, to E. M. Richards, a premium of	5.00
For the best Autumn Apples, to Mr J. L. L. F. Warren, a premium of	5.00
For the best Winter Apples, to Dr Amos Holbrook, a premium of	5.00
<i>Cherries.</i> —For the best Cherries, to Mr E. Vose a premium of,	5.00
<i>Peaches.</i> —For the best peaches, open culture, to Mrs Bigelow, a gratuity of	5.00
For the best Peaches, (under glass,) to Mr J. F. Allen, a gratuity of	5.00
<i>Plums.</i> —For the best Plums, to Mr S. R. Johnson, a premium of	5.00
For the next best, to Mr Samuel Pond a gratuity of	5.00
For the next best, to Mr R. Manning, a gratuity of	5.00
<i>Apricots.</i> —For the best Apricots, to the Hon. John Welles, a premium of	5.00
<i>Nectarines.</i> —For the best Nectarines, to Mr Thomas Mason, a premium of	5.00
<i>Quinces.</i> —For the best Quinces, to Col. M. P. Wilder, a premium of	5.00
<i>Grapes.</i> —For the best Foreign Grapes grown under glass, to Mr Otis Johnson, a premium of	10.00
For the best Foreign Grapes, open culture, to Benjamin Guild, Esq., a premium of	5.00
<i>Gooseberries.</i> —For the best Desert Gooseberries, to Mr John Hovey, a premium of	5.00
<i>Raspberries.</i> —For the best Raspberries, to Mr Thomas Mason, a premium of	5.00
<i>Strawberries.</i> —For the best Strawberries, to Messrs Hovey & Co., a premium of	5.00
<i>Currants.</i> —For the best Currants, to Mr A. D. William, a premium of	2.00
<i>Melons.</i> —For the best pair of Water Melons, to Mr John Hill a gratuity of,	3.00
For the best Musk Melons, to Mr E. Vose, a premium of	3.00

For the Committee,

E. M. RICHARDS, *Chairman.*

January 11, 1840.

THE CURCULIO.

Norton, Feb. 26, 1840.

To the Editors of the New England Farmer:

GENTLEMEN—In the spring of 1838 I sent you for publication the result of a verbal communication, which I had received from my highly esteemed friend Dr. Burnett, and which was published in your paper of that period, on the subject of the curculio. That communication detailed the results of a single experiment of his, which in that particular case had proved completely successful in insuring a large crop of fruit of the plum from the attacks of that insidious and destructive foe to good fruit. I have just received from him the enclosed letter, and also a communication of his on this same subject which was published in the National *Ægis*, in June last. These communications I forward to you for publication, as I deem them both equally important, and the hints therein contained extremely valuable. I consider it as the best article on the subject I have ever seen.

Very truly, your friend and humble servant,

WILLIAM KENRICK.

P. S.—Dr. Burnett has kindly sent me an accurate drawing of the curculio. Should you think proper to have it engraved, the drawing is at your service.

W. K.

Southborough, Feb. 22, 1840.

DEAR SIR,—I received a letter a few days since from you, desiring some information in protecting the fruit of plum trees from the depredations of the Curculio. I have not stationed a hen and chickens around a tree since the spring of 1837, because they would injure other productions which were near the trees; but I should think from what I know of the habits of the curculio, that they would prove quite a prevention. I have studied the habits and character of the curculio in the two last summers, for I consider him the only obstacle in the way of raising that fruit.

1st. I have found that the curculio is on the tree ready for its operations very early, even before the plums are large enough for it to deposit its egg in them.

2d. It continues its labors into August.

3d. It gets on to the tree by flying, though it may crawl up the body at times.

4th. It stings the fruit mostly in the night.

The same curculio that stings the plum and peach I have found repeatedly operating on the apple. I was not aware of this fact till lately, and I do not know but these may be a larger species of the same insect which stings the apple also. I should think they were from the size of the larvae often seen in apples. I should consider hens with their chickens stationed about the fruit trees, and daily shaking and jarring the trees (for the curculio always falls to the ground when the tree is shook) while the fowls were immediately under them, to prove quite a protection. The supposed remedy should be applied quite early in the spring, in order to warrant the greatest chance of success. The small birds are the natural enemy of this insect as well as most of the insect tribe, and it should be the aim of horticulturists and farmers to encourage their multiplication, and to protect them. I design to make further experiments to protect fruit trees against injuries from this insect, and should I make any discovery or advances, I shall be happy to communicate. Were it not for the curculio, most of our fruit would be comparatively fair, and all of it

free from worms. A gentleman lately informed me that apples and other fruit were free from worms in the state of Ohio.

By the request of a friend, I gave the editor of the Worcester *Ægis* last summer a small article "On the Cultivation of Plums," in which the curculio is described, and some modes of prevention are spoken of in that article. I take the liberty to send you that paper, and also an imperfect drawing of that insect in this letter.

MAGNIFIED DRAWING.

Rhynchæus Nenuphar, of Herbst.
" Ceraci, of Peck.
Curculio of Horticulturists.

No information could be more important to the fruit grower than a knowledge of the character of the Canker worm, the Curculio, and the Borer, and the best means of securing fruit trees against the injuries which they inflict.

Respectfully, your obt' servant,

JOEL BURNETT.

From the National *Ægis*.

CULTIVATION OF THE PLUM.

MR. EDITOR: Sir—I am induced to offer you some observations of mine on the cultivation of Plums. I have taken an interest in the cultivation of fruit for the last eight years, and now have several good kinds in a bearing state. The plum is one of our hardest fruit trees. During our cold winters I lost pear, apricot, peach, and several of the Baldwin apple, by the severity of the cold, but not a single plum tree. Plum trees of almost all kinds are good bearers; they usually blossom full, and the fruit sets well, and it is certainly one of the most delicious fruits we have, when in perfection. The fine kinds are wholesome and salutary, and can be indulged in even to satiety, when fully ripe, without harm. They will grow well in rather a low loamy soil; if the soil is rich, they grow fast and come quick into bearing.

But the grand obstacle in the way of cultivating this fruit, is the depredations of a small insect of the beetle tribe, which commences its operations when the fruit is quite small, and continues them usually till the first of August. This beetle is called by horticulturists the curculio—is about one sixth of an inch long, has two small bunches or protuberances on its back, and a rostrum or beak, and on this two antennæ. By this rostrum it makes a semilunar incision on the plum, into which it deposits an egg. The egg hatches, producing a worm, or larva, which burrows down into the heart of the fruit, eating it through two or three times from end to end. This kills the life of the plum, causing it to wither and fall prematurely; the worm then soon leaves the fruit and enters the ground, where it undergoes a transformation or metamorphosis, common to the insect tribe, and then comes up a new curculio, to deposit its eggs as before described. Its work is not confined to the plum, but extends to the cherry, peach, and apple, though it would seem to prefer the plum to other fruit, on account, probably, of the smoothness of the skin, and the greater ease in making the incision. It is remarkable how general its depreda-

tions are on the plum tree when unmolested; for when the tree is loaded with fruit, and large, scarcely a single plum will remain unpunctured, and consequently all will be lost to the cultivator. Some kinds of peach and apple which have a woolly or furry surface, are not attacked. Almost all the wind-fall apples (as they are called) are produced by this beetle, and upon examination will be found to contain the larvae or worm from the egg of the curculio.

The plum tree is subject to a disease on the limbs, a kind of excrescence or warty appearance, which Dr Harris says is caused by this same curculio, puncturing the tender bark and depositing his eggs under it. "These swellings, or warts, are diseases of the bark, caused by the punctures of the weevil, and the residence of the grubs. The sap vessels being wounded and irritated by the insects, throw out an increased quantity of fluid; this is re-absorbed by the bark, which is consequently swollen and thickened in substance; the over-stretched cuticle bursts, and the swelling becomes irregular, granulated, and full of fissures."

Dr Harris recommends cutting out and extirpating these excrescences and burning them before the last of June. The wounds made in so doing should be treated with mortar used in grafting.

The character of the curculio is sly and timorous; so much so, it is seldom seen unless hunted after purposely. He is not often seen in motion on the tree, but occasionally in a small crevice or crack, or the axilla of a limb, and so much does he resemble an old blossom or bud, or a small piece of bark, that he will commonly remain unnoticed. Should the observer extend his thumb and finger to take him, ten to one if he don't elude him, falling as imperceptible as a small sheet would to the ground.

The habits of this insect are not well known, I still believe, to fruit growers. I have made frequent inquiry of them for a preventive measure. Some have told me the insect crawled up the tree, and most of them have never seen it to know it. It is well to remark that it flies on the tree.

The following are some of the means of preserving fruit against the attacks of these insects.

First. All the premature fruit that falls to the ground with the worm in it, should be immediately gathered and burned. It will begin to fall as early as the 12th or 15th of June, and continue to until the middle of August, if not ripe before. This course, well pursued, will destroy the next generation of them and save the next year's crop.

Second. Shaking the tree briskly morning and night, and two or three times during the day, will very much discommodate and interrupt them from pursuing their operations—for at each concussion of the tree the insects fall to the ground, and if they recense, will soon become discouraged by this course of treatment.

Third. Let two or three hands take a sheet or sheets and spread under the tree, and then shake and jar it, and they immediately fall, feigning themselves lifeless, and appearing like a shapeless lump, and by those who are unacquainted with them, would not be taken for an animal until they moved. All that fall on the sheet should be immediately crushed. This last mode of destroying them should be practiced twice a day while any are found. In the spring of 1837, I cooped a hen and chickens about an Imperial Gage, whose fruit was destroyed the preceding year, and about all the plums matured on this tree. It is probable

that the beetles were destroyed by the brood, as they made their way to the surface of the soil. As this little animal is easily annoyed, trees standing before a store or shop or any frequented place, usually more or less escape injury. I have known trees standing near a hog pen, mature their fruit year after year, while others, standing four rods distant, as surely failed.

Mr Manning remarks in his Book of Fruits, that plums thrive best near the borders of the sea, and that the curculio is said to avoid the salt air.

If the foregoing remarks should prove of any advantage to horticulturists in the protection of fruit from injuries inflicted by this insect, or lead to minuter investigation into its nature and habits, I shall be well rewarded for this imperfect communication.

JOEL BURNETT.

Southboro', June 19, 1839.

WHITTINGTON WHEAT.

To the Editor of the New England Farmer:

As my character officially (as a seedsman) has been unadverted on, relative to some sales I made last spring of the *Whittington New White Wheat*, for Spring Wheat, when it has been ascertained (and an experiment made in my own garden proved the same) that in our climate it should be sown in the Fall, I would merely observe that no design to deceive the public was dreamed of, (as some inconsiderate persons have thought proper to remark, even in the papers.) I could have no great emolument from the supposed imposition, as my whole stock was but twenty-eight bushels, and sold at but a trifling profit, as it cost £1 per bushel in London, to which heavy expences are added. I sold it at 25 cents per quart, and gave a good deal away. My own opinion, and that of many of our first agricultural gentlemen is, that it is the finest wheat ever introduced into this country, and they, one and all, intend making a trial of it the ensuing fall.

Mr Whittington, of Surrey, England, who sent it out to me, writes in reply (26th Sept.) to my making known to him the disappointment of those who tried it, "In answer to yours I am as much vexed as I am confounded. I really am at a loss to account for the extraordinary results you communicate. I enclose you one of last year's circulars, and one of the present season's" (which are at Mr J. Breck & Co's, Boston, and where a sample of the wheat may be seen.)

"As regards its winter properties as well as spring, it has been fully tested and publicly admitted to be the best wheat in this country for rapid growth, standing uninjured through the most severe weather, and yielding by an excess of 16 bushels per acre off the very poorest soils over every other tried variety of White Wheat. As to its failure for a Spring wheat with you, I repeat, I cannot account, neither can I learn of American gentlemen here. It is of Swiss origin, which induced us to try it as a spring grain for two seasons, sowing it in February, which in this country is the latest period for sowing wheat. Our circular expresses what was done with it in 1838, and this year, 1839, we sowed on the 23d and 24th of March fifteen acres of it, and all was housed by the 25th of August. In addition to this fact, Messrs G. Wildes & Co, Mr J. Eathergill, (the London Corn Factor), Messrs Phillipson, the extensive farmers of Sutton Estate, in Surrey, have all had capital crops of it from sowings in February and March, whilst Mr Baxter, the large Flour Factor, who also farms 300

acres only nine miles from London, sowed two acres of it during the first week of April, and has carried a capital crop, he assures me fully, forty bushels per acre.

"We stand too highly connected and engaged as agents for several noblemen's estates, and farming largely, as well as being Land surveyors, for upwards of forty years, to represent falsely any article, as do also our agents Messrs Gibbs & Co. I can have no right to doubt you, but whether and what are the local causes which have created the disappointment, ought to be best known by you, and, under these circumstances, I would not advise you to sell it again as a spring grain. I regret you did not write me sooner, that I might have sent you some in time to sow the present autumn, the successful issue of which is beyond all question. I will send you 20 bushels by the next packet, hoping it may yet arrive in time for this autumn's sowing, and from which you can supply to those who may, under their hopes, insist on some sort of compensation, if it arrives in time, and your weather be mild and open. Sow the wheat, desiring it may be buried three inches deep."

The wheat sent out to reimburse, came too late to do any thing with the last autumn, but will be delivered in such quantity as was before purchased, gratis. It can be kept in a case, or glass demi-john, sealed air tight, for fear of weevil, until the proper time to sow it next fall.

GEORGE C. THORBURN,
No. 11 John street, New York.

TRIMMING TREES.

Some Farmers, I observe, are already beginning to trim their apple and pear trees. It is a saving of time to do it in the winter, but a loss of the fruit, presently, and finally a loss of the trees.

The following extract from the "Farmer's Register," is in point; and I believe all similar experiments will produce—sooner or later—similar results.

"I had a small apple tree which had been grafted with a choice fruit, and had been growing perhaps seven or eight years. There was one limb on it which I did not like, because it was growing in a wrong direction. I took it off in December, because I believed the sap to be then in the roots, and therefore at this season there would be none of it wasted or taken away with the limb, and of course the branches left would receive a greater portion of nourishment in the spring. Sometime afterward I examined the tree and found that the part or stump of the limb which remained within the surface of the body, was affected with the dry rot in its purest type. I removed this with my knife, and found that the disease had made its attack on the body of the tree itself. The tree, after the limb was taken off, became sickly, and its fruit after it began to bear was imperfect."

Dry rot may oftentimes be prevented, however, if the wounds are carefully covered with a composition made of rosin, tallow, beeswax and ochre, melted and well mixed together—and where it is necessary, for want of time in the spring, to resort to winter trimming, this method of prevention should be resorted to. It is cheap, simple, and adheres to the wound—excluding moisture—until it is healed over.—*Patrol and Democrat.*

The Farmer's Cabinet attests to the efficacy of lime as a certain destroyer of sorrel, having tried it for that object.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, MARCH 11 1840.

THE EIGHTH AGRICULTURAL MEETING

Was holden at the Representatives' Hall on Thursday evening, 6th inst. Mr Brigham, of Westboro', one of the Vice Presidents of the meeting, in the Chair. Mr Fowler, of Danvers, was appointed Secretary. The attendance was very full. The subject announced for discussion was the Small Grains.

The Commissioner opened the meeting by reading several letters from gentlemen distinguished for their intelligence and practical skill in agriculture, relating particularly to the use of the marls found in Berkshire, and to the cultivation of wheat. These marls contain nearly nine per cent of the carbonate of lime; and it had been confidently expected that they would prove highly beneficial in their application to lands, where they might be accessible, and especially to the cultivation of wheat.

Experiments only can satisfactorily decide these points; and though the results hitherto have not been encouraging they are by no means to be regarded as decisive.

The first communication addressed to the Commissioner in reply to his inquiries, was from Edward A. Newton, Esq., of Pittsfield, President of the Berkshire Agricultural Society.

Mr Newton says he thinks it too soon as yet to come to any decisive conclusions. His first experiment was on a lot which had been planted the previous year with potatoes and well manured. He spread twelve loads of marl to the acre and sowed wheat. He obtained a large crop of straw, but the wheat did not fill. This he attributes in a degree to the number of trees in the field, which was his orchard.

His next application of it was to a lot of three acres, upon which he put first twenty loads of fresh stable manure and then twelve loads of marl, and ploughed the same in. He then spread ten loads of well rotted manure to the acre, and planted corn. His crop was much injured by the wire worm. He obtained fifty bushels of corn to the acre. He did not expect any direct benefit from the marl, and obtained none; but he designs another season, to lay down this land to grass with wheat; and considers the result then will be a fair experiment of its efficacy and value. Mr Newton likewise made an application of it to carrots, but without any success; it might perhaps be better said, with an injury to the yield. He quotes the authority of Professor Madan, of Scotland, that marl sown from the pits has always a bad effect upon root crops.

The next letter was from Dr Robert Campbell, of Pittsfield, who applied it at the rate of 200 and 500 bushels to the acre upon carrots, sugar beets, and Indian corn.—He says of his Indian corn, that he could not distinguish the portion manured from that which was not manured.—“On the whole,” he says, “I do not consider that the marl was any benefit to the crops thus far, although the additional quantity applied to the beet crop was manifestly injurious. The crops were not of that kind, neither were the experiments conducted in a manner to test the utility of lime in any form. It was from fearing that my soil was wholly destitute of the carbonate of lime, that I was induced to try the marl. Another reason was, from observing that portions of my land when well manured and cultivated, did not give a good return in crops, which I was led to believe was owing to the presence of some of the deleterious salts of iron, which I hoped to be able to correct by the use of lime. It is my intention to continue the use of lime in some form, either as marl or lime in a caustic state, until I can be fully satisfied of its use.”

The next letter was from Mr Cornelius Basset, of Lee, an intelligent and skilful farmer. He says “he has not been so particular in his application of it as he ought. I put 50 loads upon about 4 acres, and the following season ploughed with corn, having dropped the same number of loads of manure in the hill.” His corn he says was excellent. He afterwards sowed this land with wheat and oats, “which were very good.” (This experiment, from the intermixture of the manure, cannot be considered as conclusive.) He goes on to say that “his potatoes yielded about four quarters in a bushel from the same number of hills more than those that did not marl.” He applied several loads to his moving land. The first season, he could not perceive any difference. The second season, in some places, he could see a marked difference—in

some lots he judged a third differ— in others he could see no difference. He adds, “I feel more encouraged to apply it than when you were here. Some of my neighbors have received much greater benefit from its application than myself; and others about the same. Esq. Porter applied some to an onion bed. The first season the onions were ordinary; the past season, on the same bed, extraordinary; he thinks the best in the county; he attributes it to marl; he applied some to old sward-bound meadow land; his grass was much better. He applied on two rows of corn marl instead of plaster, having plastered the best of the piece; he applied also the same quantity of marl as plaster, and at the same time the marled rows he thinks were full as good as the plastered ones. His land is on the banks of the Housatonic river. Another neighbor applied about half a shovelful in a hill to corn, having manured side by side in a hill with good hog manure. The fore part of the season his manured corn was the best. In the fall he would have given any one the piece of corn if he would pick out the marled. In potatoes he was more particular. He planted two rows and applied manure in the hill; two rows marl and manure, and two rows marl alone. His marl and manured rows were the best; and the marl application next; but the manured rows the least.”

The next letter read was from E. Phinney, Esq., of Lexington, on the cultivation of wheat. It is intended that this letter shall come before the public shortly in another form, and therefore we shall give scarcely an abstract of it. Mr Phinney has now cultivated wheat for twelve years, and for the last nine years with perfect success, the crop varying according to the quality of the soil, from 15 to 25 bushels per acre. He attributes his success to comparatively deep ploughing, so that some portion of the subsoil, the unexhausted treasure of the earth, is brought to the surface to be enriched by manure and atmospheric influences; and to the use of lime mixed with peat ashes, and barilla, containing about 50 per cent of lime.

He says: “The parable of the sower who went out to sow, contains much agricultural as well as moral and religious instruction. The seed that fell upon stony ground, which had not much earth, like that which is sown upon our shod-ploughed fields, sprung up and grew the better at first, by reason of its having but little depth of earth; but as soon as the sun was up and the season advanced, it was scorched, and because it had no root, it withered away. Here is an admirable lesson for farmers; and the reasoning of the sacred teacher is as sound and unanswerable in an agricultural as it is in a moral and religious view. Let the farmers then sow their seed upon “good ground,” deeply ploughed and liberally and rightly manured, and we shall have no more of the necessity of legislative bounty as an inducement to the culture of wheat.”

And in showing me, however, to judge from my own experience, I say, with hesitation, I have no doubt as to the successful cultivation of the swarded crop in all parts of the commonwealth; I mean with a due application of skill in the management and cultivation of our grounds.”

The question of Small Grains then coming up, and particularly the cultivation of wheat, several gentlemen addressed the meeting on the various topics of the use of lime for wheat, on sowing wheat upon green sward, on the prevention of smut, on laying down land with wheat, and other incidental matters.

Mr Henderson, of Sunderland, stated that he had sowed wheat upon old land or green sward inverted, and we manured it, and say, with success; but as he spoke low, we did not understand whether it were winter or spring wheat; and regret that we were unable to catch his remarks.

Mr Cole, the editor of the Yankee Farmer, then addressed the meeting. He had heard several farmers speak of sowing wheat upon green sward, and we understood him, with advantage. In respect to steeping wheat he had known one farmer to soak his wheat in brine a fortnight without injury. The editor of the Genesee Farmer had steeped Italian and common wheat for a week before sowing; they grew very well. A farmer in Ontario had steeped his wheat a month without injury. He did not believe that brine would injure it. Some farmers in New York had steeped the seed of Italian wheat without injury. Mr Hedges, of Rome, N. Y., who introduced the cultivation of the Italian swarded wheat without preparation. He had soaked it 12 hours and 24 hours in brine; it did not grow. The weather was warm. If steeped in brine and kept cool, it would not take injury. Experiments have been made of bringing to prevent smut. This was recommended on the authority of Arthur Young. His, Mr C.'s father, used to prepare his seed wheat by brining and lining it; had at

the same time sowed some dry. The dry-sown was smutted; the steeped wheat was unimpaired.

B. V. French, Esq., of Baintree, then addressed the meeting. He had made experiments in the application of lime to land. He was desirous to lay down some of his lands to grass. He objected to sowing barley in this case, because it was an exhausting crop; to oats, because they were apt to be followed with an abundance of sorrel. He sowed the Gulman wheat and obtained 23 bushels per acre. He tried the Black Sea variety, but it failed. The next year he wished to lay down some land. Here the Gulman wheat succeeded where the Black Sea wheat failed. In some parts of Baintree, and in the neighborhood and on the islands in Boston harbor, the Gulman wheat had failed.

In 1837, he wished to lay down to grass a piece of land adjoining that on which his Black Sea wheat had failed. He asked the advice of an eminent chemist on the subject of liming. He advised him to apply one hundred and sixty casks to an acre. This was too expensive an experiment; so he applied one hundred and fifty bushels. The lime was air-slacked and spread upon the land, which the previous year was in corn and potatoes. A portion of the land, which had been limed, of eight or ten feet wide, running across the piece, was dressed with strong manure. The wheat came up very well. On the 5th of July it was struck with a blight. There was no difference between the manured and unmanured parts of the field. He again advised with the gentleman to whom he had before referred, but his opinions on the efficacy of lime had undergone a change. He, Mr French, would not condemn the use of lime; but he would say his own experience was unfavorable to it. It might answer a much better purpose in old countries than in ours, and it was extensively used there and much approved. He laid this field down to clover and the product was excellent. He had obtained three tons to the acre; and having practised the method of curing it recommended by the late Judge Buel, the hay was a valuable fodder.

He had himself to say of deep ploughing. He had lately written with minutes of the examination of several Scotch and English farmers before a committee of Parliament, on the condition of English agriculture, and had read it with great interest. The Scotch farmers were decidedly in advance of the English farming, and their extraordinary success was mainly attributable to an improved system of draining and the use of the subsoil ploughing. This draining was called the Deanston system. It consisted in sinking drains at the distance of seven yards apart to the depth of three feet; narrow at bottom and filled in with stone to the height of about eighteen inches; an inverted sod placed upon these stones to prevent the falling in of the dirt, and then the whole filled up and the field left smooth. These drains were so deep as not to be reached by the plough. The field was then ploughed with a common plough, and the following year a subsoil plough, so that the whole was completely drained to the depth of eighteen inches, and in the course of cultivation some portion of the subsoil, though not in excess, was brought up to mix with the top soil and to become enriched by air and heat and light. The fields thus prepared and well cultivated and manured, produced most extraordinary crops—from 40 to 50 bushels of wheat to an acre, and other crops in proportion; and this was a permanent improvement.

(An account of this great improvement was given to the readers of the New England Farmer a few weeks since, and we strongly invite the attention of farmers to the subject.)

Mr Williams, of Alford, Berkshire county, then spoke of steeping seed wheat in brine. He did not consider it in any degree a preventive of smut. His father had steeped his wheat in brine, yet suffered much from the smut. He used brine for the purpose of floating off oats and other foul stuff, which were mixed with his seed wheat. The brine he regarded as preferable to water for removing smut, as well as other matters, because they would float in brine when they would not in clear water; but he did not consider that there was any particular efficacy in brine itself for the destruction or prevention of smut. He considered lime, however, as a perfect preventive of smut. He had sowed winter wheat upon green sward, and the result had been good. He had made a trial of laying down land with wheat and rye. On three acres, the two outside acres were in rye, the centre acre was in wheat. The grass seed was sowed on the snow in the spring. Each of the lots was plastered. The grass seed came up equally well on each lot. On the rye ground, however, the grass was almost an entire failure. On the wheat, the grass took as well as possible, and was almost as obvious to the sight as if the rye had not been sown at all with grass. He made

afterwards a similar comparative experiment with wheat, oats and barley; and for the purpose of laying down land to grass, the wheat was as decidedly preferable as in the case of rye before mentioned.

Mr Orrin Curtis, of Sheffield, in the same county, then gave his opinions and experience. He had been much in the habit of raising barley and other grains. For laying down lands to grass he considers wheat preferable to any other grain—rye he placed second, barley last. The roots of barley, and oats, and of buckwheat, run near the surface, and though they are not upon the whole more exhausting to the soil than other crops giving an equal amount of vegetable growth, yet by their mode of growth they rob the soil of that nutriment which the tender plants of grass particularly need. In an exact comparison of three pieces of ground adjoining, each in the same condition, and cultivated in the same manner, excepting that one was laid down with barley, one with oats, and one with wheat, this fact was fully established; the grass appearing scarcely at all among the barley stubble, better among the oats, and full among the wheat.

He has raised wheat on green sward with advantage; this has been, when he has been able to sow his wheat by the first of September. He would not choose to sow wheat upon a sward abounding with blue grass or quick (creeping wheat); but clover he considers an excellent preparation, and other English grasses may be turned over with advantage. That the soaking of seed wheat in brine and then liming it, is a preventive of smut. He has not failed to raise spring wheat for fifteen years; and never suffered from smut until three years ago. The seed of the Italian wheat which he had imported from Rome, N. Y., had the seeds of smut, and his crop was infected. The use of brine and lime had destroyed smut. He had learnt a good lesson on this subject from an old Dutch farmer, who was always careful to keep his seed wheat clean, and thus kept clear of smut.

In respect to the depth of ploughing, which was advisable, much must depend on circumstances. He preferred to plough not deeper than he could manure well; and he would gradually deepen his soil, and bring a portion of his subsoil to the surface, as the highest and most important advantage; that the soil should be light and porous. It was as important that air and heat should act upon the soil as moisture. In dry and light lands we might plough deep with advantage; but in cold and wet soils, if we turned over the soil, as on account of the wetness it would remain cold, the vegetable matter would not be decomposed, and would therefore afford no nourishment to the growing plants. He laid great stress upon rendering the soils accessible to heat and air, in order to promote vegetation. In ploughing, if the soil were light and dry, he would say the furrow slice flat; but if wet and heavy, he would prefer that the furrows should lap one on the other; as on such lands he had always got the best crops, when he had turned his furrows up-hill.

He has made repeated trials of lime in different soils, but has found no advantage from its exceeding in potato hills. Here it increased and improved the crop. He has tried it on grass and oats, but without success. He has cultivated wheat and corn for years. His usual rotation is first, corn; second, spring rye or spring wheat; third, winter wheat. His manure is given to his corn.

Mr Jones, of Athol, followed. He had applied lime to his land for the destruction of worms, as he deemed it beneficial for this object. He preferred to get his seed wheat from the north, and had sowed it several years in succession. He considered that weeds were extremely prejudicial to wheat. He was accustomed to dissolve lime in water, and apply it at the rate of one quart to a bushel. He had no smutty wheat. He sows his wheat early and had never failed to obtain a good crop. He took care to plough his ground fine, and in that way get a start of the weeds.

Mr Hardy, of Waltham, inquired whether our attention should not be mainly directed to raising Indian corn instead of wheat. It was replied to him that corn was undoubtedly upon the whole a more valuable crop than wheat, and that every attention should be paid to its improvement. If other persons can raise one hundred and thirty bushels on an acre, we ought never to be satisfied until we can reach the same point. With good cultivation, undoubtedly, we might raise the bread stuff which is consumed in the State without the aid of one quart to a bushel, and forty of wheat can be got to an acre, we ought not to be satisfied until we have reached it. It might not be easy to accomplish this, but we should try. It would require expense to put our land in a proper condition of fertility; but this need not be regarded, provided the return will not only meet it, but much more. The investment of money in such improvements where the profits

are comparatively certain, is a judicious application of capital.

SILK CONVENTION.

We earnestly hope that our friends in the town and in the State, will not forget the silk meeting, which is to be held at the Representatives' Hall on Thursday evening, (i. e. to-morrow.) We hope, likewise, that those persons who have samples of raw or manufactured silks, will do the public the favor to exhibit them at the hall on Thursday evening.

The last meeting voted to invite the ladies who may be interested in the matter to attend the silk meeting. We respectfully extend the invitation, and hope it will be favorably received by them.

THE NE PLUS ULTRA OF SEED SOWERS

Mr Willis, the ingenious inventor of several machines calculated to abridge the farmer's labor and facilitate some of his principal operations, is now engaged in perfecting an improvement on his Seed Sower of last year's construction, which we understand will materially enhance the value of that instrument as an aid to the farmer in sowing his seeds.—The various labor-saving implements which Mr W. has offered for the test of the agricultural community, have been highly commended by those who have given them a trial, and are considered by intelligent cultivators as important aids in the economy of the farm; and no one of his machines has won a higher repute than his Seed Sower,—which facts well attested by the great demand for these instruments, all that were manufactured the last year, (amounting to upwards of eighty,) having been disposed of, and orders made for many more which the inventor could not supply.

If any of our agricultural friends have concluded to furnish themselves with an instrument of this kind, we would advise them to defer purchasing until they shall have examined the latest improvement of Mr Willis, which we understand will be completed and ready for inspection at the Agricultural Warehouse, Nos. 51 and 52 North Market st., in the course of a few days.—Com.

BRIGHTON MARKET.—MONDAY, March 9, 1840.

Reported for the New England Farmer

At Market 245 Beef Cattle, 15 pairs Working Oxen, 20 Cows and Calves, 200 Sheep and 110 Swine.

Prices.—Beef Cattle.—We advance our quotations to conform to sales. A few extra \$7.25. First quality, \$7.00—Second quality, \$6.50 a \$6.75. Third quality, \$5.50 a \$6.00.

Working Oxen.—A few sales were effected; prices not public.

Cows and Calves.—Dull. A few were sold at \$25, \$28, \$32, \$37, \$40, and \$42.

Sheep.—All at market were of a fine quality. Lots were sold at \$3.00, \$4.50, and \$5.50, and \$11.

Swine.—All were previously contracted for at something more than \$6. A small number only were retailed and prices were not established.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded Northern exposure, week ending March 8.

Feb. 1840.	7 A. M.	12 M.	5 P. M.	Wind.

Sun. day,	8	5	22	25	N. W.

PUBLIC ACTION.

The subscriber having leased his Farm near this city, will offer for sale, on sale, term, on Wednesday, the 23th day of March inst. all of his valuable stock of neat Cattle, being about forty head, mostly high bred animals, among which is one full blooded Durham Bull, four years old, from the stock of Col. Powell, of Philadelphia; ten or twelve Cows; three very fine yoke of working Oxen. The remainder young stock, very fine.

See *postere* and terms literal. If the weather should be stormy, the sale to take place the first fair day.

Hartford, March 11, 1840 J. JOSEPH MORGAN.

BOX.

For sale at the Garden of SAMUEL DOWNER, in Dorchester a small lot of tall Box. Also, a large lot of short box, with fine roots and will make a neat border.

March 11. 31

REPORT ON TREES AND LIVE HEDGES.

The Committee of the Massachusetts Society for the promotion of Agriculture, "On Trees and Live Hedges," have attended to the application of Daniel Stebbins, Esq., of Northampton, who has submitted in due and regular form, his application for a premium on an acre of the Yellow Locust, containing over 1000 trees. The lumber made requisite by the Society.

The practice of Dr Stebbins will be published, and is encouraging in its course.

It is not clearly stated whether the soil was cultivated about the trees, or more extensively. This it would seem, might be an advisable practice.

Still the growth, considering the lightness or sterility of the soil, was equal to what might be expected in such case.

It would hardly be thought supposable, that the Locust tree could favor the growth of the grass about it; only when compared to other trees from its foliage, it makes less shade. Still there are many who hold the opinion of an actual increased vegetation by the proximity of this tree with great confidence.

Of the advantage to be derived from the raising and multiplying the Locust, there would be but one opinion, if the ravages of the borer could be prevented.

In a separate communication which accompanies his others, Dr Stebbins speaks highly of the benefit to be derived from an unbragous situation, and of creating a shade previously to setting out the locust, or of placing it in the forest even, where it has been asserted the worm would not follow. Such is the durability and value of the timber of the tree for most uses, that its protection and preservation are well worthy the efforts of all agriculturists, and to such the perusal of the remarks of Dr Stebbins may be well recommended.

It is said by some that these pestiferous worms or insects that annoy the locust are lessening in number, and it is thought that they may disappear, after having had a sojourn of three score years with us.

Some of the tribes, however, seem to be making their ravages on the elm and other trees, which have not before suffered.

To this the attention of our husbandmen is called, and we hope it may not be in vain.

For the communication on the aforesaid plantation, your committee report that the premium of twentyfive dollars be allowed to Daniel Stebbins, Esq.

The same committee have also attended to a communication made by the same gentleman, on the subject of the Mulberry tree, in its relation to the silk culture, and are of opinion that it contains many useful remarks—and further, that in the introduction of a new variety of the mulberry tree by importation from Canton, of the seed which promises a more hardy tree, and produces silk of a better quality. Dr Stebbins is well entitled to the premium of fifty dollars.

It will be seen by this gentleman's communication that he has his doubts whether it would be safe to leave this tree of new variety out through the winter; an object most earnestly to be looked for.

It is to be hoped that this, or some other mulberry tree may suit some parts of the climate of New England, or if not, of the United States, and be so cultivated that the immense import of silk to

the extent of 20 millions of dollars as is stated, may be at least lessened.

The committee further report that Dr Stebbins has also made a communication, which is annexed, on the subject of Live Hedges, in which it will be seen he has brought forward a thrifty growth of the Honey Locust, of about 160 rods, which it is thought may be interlocked so as to form a substantial and durable hedge, which would offer an unexpected variety to this mode of enclosure, and be considered highly ornamental by many.

But as the said hedge might, it is feared, be subject to the borer, and at any rate is not so far completed as to ensure its practical utility, however favorably inclined to encourage Dr Stebbins's arduous and enterprise, so laudably exercised, your Committee think it may be better considered hereafter.

One other application has been made by Mr Benj. N. Childs, which contains many good suggestions of his experience in regard to the mulberry or silk culture. But it is to be wished that the objects aimed at for the advantages of the culture had been further set forth.

It is to be regretted that his own course of experience seems to indicate a suspicion or distrust of his labors, as he observes what course he should pursue "were he to commence again."

The object of the Society it will be perceived is to bring forward whatever favorable results might be derived from experience, and what means might best conduce to enable the mulberry tree to sustain the rigor of our climate.

This is the desired result, and to be pursued as far as reasonable expectation may be indulged;—when that fails, it must, however reluctantly, be given up.—Of the heading down of the white mulberry, the practice needs confirmation; and as to the difficult and troublesome expedient of the removal into cellars of some species of the mulberry tree every fall, it must operate in its effects in a manner highly discouraging.

The suggestion made by Mr Child for the extirpating of the borer from the apple tree, adds to the weight of general opinion that some effect may be produced by the use of ashes, lime and other caustic matter on the earth about the trees. It is to be hoped that the commendable practice herein may be continued by him, as well as pursued by others. It may be that even the canker worm may be made uncomfortable and be kept aloof from our foliage and fruit. All of which is submitted.

By order of the Committee,

JOHN WELLES, Chairman.

MR. STEBBINS'S STATEMENT.

To Peter C. Brooks, Wm. Prescott, E. H. Derby, Josiah Quincy, jr., and Elias Phinney, Esqrs., Committee of the Massachusetts Society for Promoting Agriculture:

GENTLEMEN—Under the articles of "Trees and Live Hedges" of not less than 50 rods, which shall be in the most thriving condition in 1829, I embrace the privilege of informing you that in the year 1824, I transplanted from my nursery four thousand two hundred honey locust trees, from the seed, being two years old, and set them around the borders of a twelve acre lot, about 160 rods, averaging about half a foot apart; some portions of the lot adjoin heavy timber land, is partially shaded and have grown but indifferently: other parts having a better exposure, have grown very well, from 5 to 8 feet, and capable of being so interlocked, as to make a durable and valuable fence.

On a piece of dry sandy soil, situate between a

portion of the honey locust hedge and the yellow locust grove, described in another paper, I had planted out some thousands of Large Leaf Canton layers, which flourished very well, except on the borders of the above mentioned hedge and grove: about one rod in width on either side, the mulberry trees were of small size, of 4 to 6 inches, while other parts out of the reach of the roots of the honey and yellow locust, the trees were from two to four feet, on the same quality of soil: but where the roots extended under adjoining grass ground, did not perceive any injury.

All of which is respectfully submitted by

DANIEL STEBBINS.

At the request of Dr Daniel Stebbins, we have examined and measured his honey locust hedge, on Rocky Hill in Northampton, and find that more than fifty rods of said hedge are in a flourishing condition, and in our opinion will make a substantial hedge, the whole length of which is over one hundred and sixty rods.

THEODORE WRIGHT,
WILLIAM W. COOK.

Northampton, Sept. 24, 1829.

DOMESTIC ECONOMY.

Potash and soda are the two common and abundant alkalis used in every family every day. The first in the form of soap, pearlash, saleratus, quick lye, salt, &c. The other in the form of common salt, (muriate of soda,) and sometimes in other combinations.

Lime and magnesia are called alkaline earths: the former is frequently put with ashes in leach tubs, where it absorbs the carbonic acid combined with the ashes or potash, and by that means gives it greater power in acting on the grease or oily matter used for the soap. It is more effectual than red hot horse shoes in keeping witches from the soap, and is more certain than either the new or full moon, in gratifying industrious housewives with "good luck" in this branch of domestic economy.

Acids and alkalis neutralize each other. Consequently, if an accident occurs from vinegar, sulphuric acid, (oil of vitriol), nitric acid, (aqua fortis), muriatic acid, (spirit of salt,) or any other acid, apply potash, soda, ammonia, quick lime, magnesia, or some alkali, or alkaline earth.

If an accident occurs from an alkali, apply vinegar or a weak solution of some of the stronger acids.

By a knowledge of the properties and the relations of the two classes of substances constantly used by house-keepers, stains on garments can frequently be removed or prevented, cooking improved, and frequently life saved.

Oxygen is the vital portion of the atmosphere, and the agent which supports respiration, sustains combustion, produces rust on metals, changes the juice of the apple, first into sugar, then alcohol, then vinegar, and finally putrefaction; causes light and sour bread, darkens the shade of certain colors, and destroys others, and produces some influence on every thing at all times.—*Genesee Farmer.*

THE NEW ENGLAND FARMER

Is published every Wednesday Evening, at \$3 per annum payable at the end of the year—but those who pay within sixty days from the time of subscribing are entitled to a deduction of 50 cents.

TUTTLE, DENNETT AND CHISHOLM, PRINTERS.

 February 19.

STRAWBERRIES.

Those who are desirous of cultivating this delicious fruit are respectfully informed that the subscriber has succeeded, after a number of years experimenting upon the Strawberry, not only in obtaining new varieties, but in ascertaining the best method of cultivation.
 Specimens of the fruit grown in his Garden have been exhibited at the Massachusetts Horticultural Society Rooms, the four past years, and are also too well known in Faneuil Hall Market to need particular notice here.

He has for sale at his Garden, in Brighton, Mass., the following eight varieties of Plants. They are of superior stock and quality, all warranted to be truly named and free from the mixtures often found in those offered for sale promiscuously.

Those who are in want of Strawberry Plants, are respectfully invited, and they will find it interesting, to call at the Garden and see the manner of cultivation. The method of cultivation, and any information desired will be cheerfully given.

Warren's Seedling Methuen—A new and valuable kind, a free bearer, fruit very large and juicy; fruit measuring four and a half inches have been exhibited the past season.

Melrose Castle—Fruit extremely large, high flavored, and showy. Specimens of this kind have been exhibited at the Horticultural Rooms for two years past, measuring five and a half inches in circumference.

Bath Scarlet—Fruit large, full bearer, and beautiful scarlet.

Early Virginia—This is considered the earliest fruit—a free bearer, hardy, and very early; decidedly a fine kind for market.

Royal Scarlet—Fruit long oval shaped and juicy.

Hawthorn—Fruit smaller but very numerous.

English Wood—Fruit well known.

Monthly—Fruit is gathered from the vines from June to October, and in good quantity and fine quality.
 Orders left at the Garden, or directed to the subscriber, Brighton, Mass., or left at Messrs. J. Breck & Co's Agricultural Warehouse, Boston, will be carefully and promptly attended to, and all plants will be carefully packed and forwarded agreeably to directions.

JOSEPH BRECK & CO. WARREN.
 Nonantum Vale, Brighton, Mass., March 4.

FLOWER SEEDS—CHOICE VARIETIES.

JOSEPH BRECK & CO. have received a choice assortment of Flower Seeds from England and France, which, in addition to what have been raised under their own inspection, embrace the finest collection to be found in the country, including all the new Annuals, Biennials, and Perennials worthy of cultivation; neatly done up in papers of 6 1-4, 12 1-2, and 25 cents each. For sale at 51 and 52 North Market Street.
 February 5.

WINSHIP'S NURSERIES,

BRIGHTON, MASS.

The proprietors of this Nursery are now ready to receive orders for their extensive assortment of Fruit and Ornamental Trees, Forest Trees, Shrubs, Herbaceous Plants, Roses, Green House Plants, Vines, &c.

Orders from a distance will be properly packed to go with safety to any part of the United States, and will be delivered in the city free of expense.

The Nursery grounds are five and a half miles from the city, by the Worcester Railroad; cars stop three times a day. Orders by mail addressed to Messrs. WINSHIP, Brighton, Mass., will be promptly attended to.

Fruit and Ornamental Trees, Mulberries, &c.

Fruit Trees of all the different species, of the most celebrated and surpassing kinds; the collection now offered is large. By the catalogue of Fruit and Ornamental Trees and Shrubs, Roses and Herbaceous Flowering Plants, for 1839, is now ready and will be sent to all who apply. In that catalogue the very best kinds of fruit, so far as proved, are particularly designated by a *.

100,000 Morus Multicaulis Trees, or any other reasonable quantity, or Cuttings of the same, are now offered for sale. The trees are genuine, all being raised by the catalogue, either at his Nursery here or at his Southern Establishment at Portsmouth in Lower Virginia. Also, the Elata, Canton, Moretti or Alpine, Broussa and some other Mulberries, Cockspur, Thous and Buckthorns for hedges, &c.
 All orders shall be promptly attended to, and trees will be securely packed for distant places.

WILLIAM KENRICK.

Nonantum Hill, Newton, March 4, 1840

March 11. JOSEPH BRECK & CO.

Green House Plants.

Green House Plants of every description furnished at short notice, and well boxed, so that they may be sent to any part of the country in safety.

March 11. JOSEPH BRECK & CO.

EARLY CEDO NULLI PEAS.

These very superior Early Peas, every way worthy of their name, are again recommended, and challenge any pea in America to beat them, being ready for the table on the 25th of May (if sown in March)—are, moreover, *dear* and *im-* mense bearers. All who had them last season, gave them the character of being not only the earliest, but best pea ever raised. The following short note near home will give an idea of their success; it is from Mr Vaughan, Long Island, dated 26th May, 1839. "On the 7th of March I planted your cedo Nulli peas, and have them on my table today; here, the early part of this month, has been as favorable as April, they would have been, I doubt not, ten days sooner, as they were in bloom the 1st of May." Other references near this city, and in Dutchess county, can be given, if required. Price 50 cents per quart; may be planted the moment the ground can be worked.

Also, Early Warwick Peas—a fine sort—25 cents per quart; Early Race Horse (a new kind from England) 30 cents per quart; All varieties Dwarf Green Marrows, 50 cents; Dwarf Blue Imperial, 25 cents; and the fine Dwarf Marrows, 25 cents. Also, English Broad Windsor Beans, Sword Long Pod Beans, Early Mazagan Beans, 25 cents per quart. These should be planted in March, to succeed in our climate. Also, Early York Cabbage, Cauliflower, Broccoli, Purple Egg Plant, Tomato, Squash, Pepper, Early Scarlet and British, &c. &c. suitable for hot beds. Also, Early Potatoes, several varieties. GEO. C. THORBURN, 11 John Street, N. Y. & March 11, 1840.

PLOUGHS.

Constantly on hand, a good supply of Howard's Improved Cast Iron Plough.

This implement, one of the oldest and most useful employed on a farm, has undergone of late years, a wonderful change in all its most essential parts, and has been greatly improved. The C st Iron Plough is now most generally used among the best farmers, and considered decidedly the best. Among the different ploughs now made of cast iron, Howard's stand unrivalled. They have been used, and have in all cases been approved by them. At the Brighton Cattle Show at the exhibition in October, 1832, they received the premium of \$10, awarded as being the best plough presented.

Extract from the Report of the Committee.

"The Ploughs were all of cast iron, and by six of the most approved manufacturers. The one by Mr Charles Howard of Hingham, was a superior implement, considerable improvements having recently been made by him, in making the mould board much longer than usual, and swelling the breast of the share, so as to make every part bear equally, by which means the plough runs more true and steady, is always free from carrying forward any earth, and wears perfectly bright; and being made on mathematical principles, he informed the committee he could make the different sizes always the same.

The duty of awarding a premium "To the Plough which shall be adjudged best of all those used at the Ploughing Match," devolved on the two committees, and they agreed unanimously to award to Mr Charles Howard of Hingham, for his new and improved Plough, \$10.

JOHN PRINCE, Chairman of Single Teams.
JOHN PRINCE, Chairman of Double Teams.

Also, a good assortment of other Cast Iron and Wood- en Ploughs; Willis's Improved Cultivators; Chandler's Improved Double Harrow; Loek's Garden and Field Rollers; English Scarifiers; Davi's Improved Patent Dirt Scraper, &c. &c.

JOSEPH BRECK & CO.

March 11, 1840.

GREEN'S PATENT STRAW CUTTER.

JOSEPH BRECK & CO at the New England Agricultural Warehouse and Seed Store, Nos. 51 and 52 North Market Street, have for sale, Green's Patent Straw, Hay and Salk Cutter, operating on a mechanical principle not before applied to any implement for this purpose. The most prominent effects of this application, and some of the consequent peculiarities of the machine are:

1. So great a reduction of the quantity of power requisite to use it, that the strength of a half grown boy is sufficient in wauk it very efficiently.
2. With even this moderate power, it easily cuts two bushels a minute, which is full twice as fast as has been claimed by any other machine even when worked by horse or steam power.
3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.
4. The machine is simple in its construction, made put together very strongly. It is therefore not so liable as the complicated machines in general use to get out of order.

WILLIS'S LATEST IMPROVED SEED SOWER.

STILL LATER.

Willis has made some considerable improvement in his Seed Sower for the present year, making it as complete as time and hard sudy can possibly make it. He sold of the last year's improvement, over eighty machines, being all that was made (and could have sold at least fifty or sixty more had they been made) every one of which gave universal satisfaction. In using this machine, the farmer may be certain that his seed is put into the ground, and at the same time in the best possible manner. There has been a great difficulty in machines for sowing garden seeds; they are very apt to clog up, and the farmer might go over an acre of land and not sow a single seed; but not so with this; it is so constructed, that it cannot possibly clog. In using this sower, the farmer can save one half of his seed, and do the work at less than one quarter the expense of the common way of sowing his seeds, and have it done in a much better manner; it opens the furrow, drops the seed, covers it over and rolls them down. It will sow any kind of Garden Seeds; say Ruta Baga, Mangel Wurzel, Turnips, Carrots, Beets, Parsnips, Onions, &c.

Improveo Hays Sowers—Calculated for sowing small Garden Seeds, and very useful for the purpose intended. March 11. JOSEPH BRECK & CO.

VEGETABLE CUTTER.

Willis's New Improved Vegetable Cutter. This machine is calculated for cutting up vegetables and esculent roots for fodder, and is one of the most useful and economical machines that the farmer can use. The subscribers feel great confidence in recommending this machine to the public; they are aware that it has been long wanted and they now offer a machine that cannot fail to give satisfaction upon a fair trial. It will cut with ease from one to two bushels per minute, in the best possible manner, and is not liable to get out of order, being made in the most substantial manner. No farmer should be without one of them. For sale at the Agricultural Warehouse, 51 and 52 North Market Street. December 18. JOSEPH BRECK & CO.

AGRICULTURAL BOOKS.

- JOSEPH BRECK & CO. offer for sale a great variety of Agricultural Books, among which are the following: London's Encyclopedia of Gardening.
- " " of Plants.
- " " of Agriculture.
- " " Suburban Gardener.
- Forbes's Hortus Woburnensis.
- Practical Agriculture, by David Low.
- Chaptal's Agricultural Chemistry.
- Hogg on the Cultivation of the Carnation and other Florist's Flowers.
- The Florist's Calendar.
- Friggeman's Gardeners' Assistant.
- Pescudier's American Gardener.
- Complete Farmer.
- Kenrick's Orcharist.
- Manning's First Book of Fruits.
- Sayer's Fruit Garden Companion.
- " " Flower Garden Companion.
- Treatise on Sugar Beet, by David Lee Child.
- American Swine Breeder.
- Mowbray on Poultry.
- Monography of the Genus Camellia.
- Dennis' Silk Manual.
- Collyer's
- Kenrick's Silk Growers Guide.
- Whitmarsh on the Mulberry Tree and Silk Worm.
- American Florist.
- Parley's Cyclopedic of Botany—The Young Florist.
- Wicks' Treatise on Bees.
- February 5.

ELEMENTS OF PRACTICAL AGRICULTURE.

Just received, a supply of the Elements of Practical Agriculture, comprising the cultivation of roots, the husbandry of domestic animals, and the economy of the farm. By David Low, Esq. F. R. S. E. Professor of Agriculture in the University of Edinburgh. Second edition, with numerous engravings: 718 pp. London published. For sale by JOSEPH BRECK & CO., No. 51 and 52 North Market Street. February 5.

URATE AND POUDERETTE.

The Company known in the City of New York by the name of "THE NEW YORK URATE AND POUDERETTE COMPANY" has been incorporated by the Legislature of the State of New Jersey, by an Act, entitled "An Act to Incorporate THE LOUI MANUFACTURING COMPANY," for purposes of Agriculture, with a Capital of 2000 Shares, each Share \$10, to be hence equal to a Capital of \$20,000.

A Pamphlet has been published containing particulars and very important information to Farmers and Gardeners, a Copy of which may be seen at this Office, or procured from A. DEY, No. 71, Cedar St., New York.

The particular attention of the reader is requested to the following description for a part of the Stock of "THE LOUI MANUFACTURING COMPANY," will be open at the house of Moses Miller, keeper of the Eagle Hotel, in Jersey City, opposite the City of New York, on Wednesday and Thursday, the 8th and 9th days of April 1840, from 10 o'clock in the forenoon until 3 o'clock in the afternoon of each day, and the payment of \$25 on each Share will be required to be paid at the time of subscribing, (either in Specie, or in Bank Bills of Specie paying Banks.) See Section No. 4 of the Act of Incorporation.

It may be, if the whole 1500 Shares shall be subscribed for, that nothing more than the 825 may be called in upon this Stock; but if any person chooses to pay the whole amount, he will draw dividends accordingly.

2d. If 500 Shares shall be subscribed for, on the 8th and 9th days of April, 1840, and it is not ascertained they will be, a further subscription of 500 Shares by Farmers and Gardeners exclusively, will be opened at the Office of D. J. & Elmendorf, No. 71, Cedar street, in the City of New York, and be continued open 60 days, commencing on Monday the 13th April, 1840, from 10 o'clock in the forenoon until 3 o'clock in the afternoon of each week day, and to continue open until the 20th day of June inclusive, or until the whole of the said 500 Shares shall be subscribed for; as soon as these 500 Shares shall be subscribed for, the books will be closed. The Dividend on these 500 Shares will be 20 cents on each Share, for 5 years, which is equal to 20 per cent. per annum, so that at the end of 5 years they will have received back their whole money. See Section No. 6.

The object of the Company in procuring Stockholders is to procure consumers, and therefore they prefer Farmers and Gardeners to subscribe one Share of the reserved Stock, rather than five shares to which each is entitled, and it is believed the other 1500 Shares of the Stock of the Company will turn out equally valuable, but then there is no authority given by law to the Company to guarantee that 20 per cent shall be paid in Poudreite. It is expected that the Dividend on the reserved Stock will be made, half in May and half in September, in each year, and therefore the whole amount of the reserved Stock, say \$100 each Share, must be paid for at the time of subscribing.

3d. Persons disposed to subscribe, may authorise any person to do so for them as follows:

"I, _____ of the Town of _____ in the County of _____ do hereby authorise _____ (or Gardner as the case may be,) do hereby authorise _____ to subscribe my name for _____ Shares of the Stock of the Loui Manufacturing Company, and pay the monies required to be paid at the time of subscription.

Witness my hand this _____ day of _____ 1840.

WITNESS PRESENT.

The subscribers are not held responsible to pay any thing beyond the amount specified at the time of subscribing.

One number of Farmers in one neighborhood may authorize one of their number or any other person to subscribe for them.

4th. AGENTS.—A number of Persons have already been appointed as Agents in different parts of the United States. The Company allow Agents a commission is to be paid for the trouble on the next amount of the cost of the Poudreite.

By the 6th Section of the Act, Farmers and Gardeners exclusively are secured the preference of a bonus equal to \$45,500 over any other consumers. They are secured an annual dividend of 30 Bushels of Poudreite for every 100 dollars they invest in the reserved 500 shares of the Stock of the Company, which at the price the Company have sold and are selling the manures, gives a dividend of 20 per cent. per annum for 5 years; after which they divide equally with the other Stockholders. It is believed, however, from data which have been furnished in a pamphlet, that the dividends on all the stock will not be less than 20 per cent. per annum.

One cent's worth, under the provision of the 6th Section, will manure 10 hills of corn. One gill of Poudreite to each hill of corn in 1839, ripened corn in three months from the time it was planted, so far as to render it too hard to eat as green corn, which would save it from destructive effects of an early frost.

But one of the greatest advantages that Poudreite has over every other manure, is the saving of labor in its transportation to the farm and its application to the soil. The saving is one half in the amount of cost, labor and expenses attending the same.

Any Farmer in moderate circumstances who loans his money at 6 per cent. interest per annum, may take one share

in the stock of the Company which would cost him \$100, and receive a dividend of 50 Bushels of Poudreite which would cost him 12 cents per Bushel, and will do his land and crop more good than 50 loads of the best horse manure, that would cost him \$750, besides the labor and expense of carting and putting it on the land.

If any person wishes further information on the subject, they will please apply to ANTHONY DEY, either in person or by Letter, directed to him at his office, N. 71 Cedar street, New York.

New York Urate and Poudreite Company.

JOSEPH BRECK & CO are agents to receive subscription for stock in "The New York Urate and Poudreite Company."

The manures are not divided among the Stockholders, as those belonging to another establishment, but sold, to applicants, for cash on delivery. Orders are supplied in the order of time in which they are received. Urate 50 cents and Poudreite 40 cents per bushel, with contingent charges for bags or barrels, &c.

The material is disinfected and rendered free from offensive smell, by a compound, every part of which is in itself a good manure.

The experience of the past and present years, 1838 and 1839, on Long Island, has satisfied many of the farmers that these manures have the quickest operation upon vegetable matter, producing greater abundance, and the cheapest of any manure they have ever tried.

Amplified instructions for their use, the result of practical experience, will be furnished on application. The effect of Poudreite upon Grape Vines and Maras Mallicoata, is beyond all comparison. JOSEPH BRECK & CO, Agents.

March 11.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that good bones form the most powerful stimulant that can be applied to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone, and solicits the patronage of the agricultural community. Price at the Mill 35 cents per bushel; put up in casks and delivered at any part of the city at 40 cents per bushel, and no charge for casks or carting.

Also, Oyster Shell Lime, price 10 cents per bushel at the kiln; put up in casks four bushels each at 60 cents per cask delivered at any part of the city; and Ground Oyster Shells.

Orders left at the Bone Mill, near Tremont road, in Roxbury and Dover Mills, New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

March 4, 1840.

NATHAN WARD.

FARMS FOR SALE.

For sale, a farm in a high state of cultivation, situated in the southerly part of Needham, bordering on Charles River, pleasantly situated, and within one quarter of a mile of Needham and Dover Mills, and within six miles of Dedham Court House, containing about 55 acres of land suitably divided into tillage and pasturing; well watered, and mostly fenced with good stone walls.

There is a young orchard containing about 150 choice Fruit Trees in a flourishing state; a large and convenient dwelling house; a new barn 40 by 60 feet, with a store and Granary connected with it, and cellar under the whole, with a first rate piggery. If said farm is not sold by the first of April next, the house and store will be to let. The store is convenient and well situated for trade.

Also—a small farm situated in the northerly part of Dover, and within half a mile of the above named mills; a desirable location for a school, containing about 20 acres of land, and well watered; with house, barn, and out-buildings.

The stock and farming utensils of the said farm will be sold at public auction on Wednesday, 18th March.

For further particulars inquire of LEONARD BATTLE, in Needham, near said farms, or CALVIN FRENCH, on the premises.

Needham, Feb. 26, 1840.

FARM FOR SALE.

For sale, a superior farm of nearly fifty acres, between Boston and Lowell, 15 miles from the former place; on which is situated a convenient dwelling house, barn, and other buildings in good repair, and an orchard of choice fruit trees. For further particulars inquire of the subscribers, No. 52 North Market Street. JOSEPH BRECK & CO.

February 26.

6w

TO FARMERS.

500 casks Lime, of good quality, for sale by the subscribers at their Wharf Front Street.

We would remind consumers of this article that the casks are larger and have at least one fourth more in quantity than in former years. Price 1½ cents per cask.

February 26.

CAKLET & WILLARD.

4w

Fruit and Vegetable Garden, and Mowing Land, Two Miles from the City. To be Leased.

The subscribers offer to let on a lease of two or more years, the land situated in Dorchester, (about two miles distant from the Old South Church, Boston,) belonging to Z. Cook, Jr. There is a garden on the premises of about 20 acres, having a southern aspect; well filled with fruit trees of every kind. The land is rich and strong, and can be made to yield early and abundant crops, and from its vicinity to the Boston Market, offers the greatest inducement. The remainder of the upland is now laid down to grass, of which it yields abundantly, and there are several acres of salt marsh immediately adjoining. A large and convenient barn is also upon the ground.

The above will be let upon the most favorable terms, on application to
COOK & COFFIN,
No. 65 Commercial Wharf.

FOR SALE.

An excellent Farm, pleasantly situated about 100 miles from the city, containing about 100 acres. For full description, particulars, &c. inquire at this office.

Also—a situation wanted by a man with a small family to occupy a farm.
January 30. 4w

URATE AND POUDERETTE.

JOSEPH BRECK & CO. would inform their friends and customers that they are agents for selling Urate and Poudreite, which will be delivered at their store, at New York Prices, with the addition of expense of freight and trucking.

Also—Agents for selling BONE MANURE and Oyster Shell Lime.
March 11.

FOR SALE OR EXCHANGE.

A valuable farm in Harvard County of Worcester, the well known Bromfield Place; an excellent dairy farm, well wooded, the house spacious, fitted for two distinct families. The situation among the most pleasant to be found, especially for agrarians or High School. Bordering a part of the farm is a beautiful sheet of water, containing two islands belonging to the estate. Inquire of the Subscriber at SOUTH NAITICK.
March 4, 1840. I. H. T. BLANCHARD.

SITUATION WANTED.

To take charge of a farm, by a careful and experienced hand. Apply at this office.
March 4. *

ROHAN POTATOES.

For sale by S. LOTHROP, West Springfield.
March 4. 8w

FOR SALE.

A Bear and Sow 15 months old. Also 3 Sows 8 months old. Full Blood Berkshire, from the stock of C. N. Bennett, Albany. The sows are all with pig. Inquire of February 19. JOSEPH BRECK & CO.

FARMER WANTED.

Wanted, as an assistant in the House of Reformation at South Boston, a farmer or gardener without any family. One who understands shoenaking or joiner's work, would be preferred. He must be a man of strict religious principles; not addicted to liquor or tobacco; good natured, and fond of children. Wages liberal. Inquire at the Directors' Office, Faneuil Hall, or at the Institution, South Boston.
GEO. F. HASKINS,
Superintendent House of Reformation.
March 11. 11

ROHAN POTATOES.

For sale at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at 85 per barrel. October 16. JOSEPH BRECK & CO.

ROHAN POTATOES.

Wanted, a Gardener of steady habits, that understands raising vegetables and taking care of fruit trees. An American, with a small family, would be preferred. None need apply without good recommendations.
February 19.

GARDEN MATS.

For sale at the New England Farmer, 100 dozen Garden Mats, of extra quality, for covering hot beds, &c.
Feb. 12. JOSEPH BRECK & CO.

NEW ENGLAND FARMER,

[NO. 37.]

N. E. FARMER.

AN ADDRESS

Before the Essex Agricultural Society, at Georgetown, Sept. 26, 1839. By ALLEN PUTNAM, of Danvers.

MR. PRESIDENT AND GENTLEMEN:—I would gladly have been excused from attempting to bring a contribution to the exhibitions of your Society, until such a time as I could offer something that was nearly ripened. There are, no doubt, matured grains and delicious fruits, in the field in which I am honored with the privilege of gathering; but having an unpractised eye, every thing there seems to me unripe and unfit to set before this company. How can it be otherwise? Only a little more than two years ago, these hands had had no acquaintance with the plough and the scythe since the days of my boyhood. Up to the present hour, I have never cultivated a rod of land that belonged to myself, or in the produce of which I had any direct pecuniary interest.

Broken down in health by the confinement and exhausting exertions of professional labors, the quiet and the employments of the paternal farm were resorted to as the most skillful physicians and efficient restoratives. There, where I have been little else than a mere laborer in carrying forward the operations upon the farm, and that too in the short term of less than three years, have I received nearly all my available schooling in the science and art of husbandry. The situation has afforded neither inducements to make such minutes, nor opportunity to try such experiments, as enable me to address an assembly of experienced farmers, in a manner that will be satisfactory to myself, or instructive to those who hear me.

Though well aware that assertions, without something like proof of their correctness; that theories unsupported by experiments; that second or third hand statements of facts are far from being what the occasion demands, yet I am obliged to tell you what I *think*, rather than what I *know*; to give details of my conjectures, rather than the results of experience and extensive observation.

The lessons which experience is supposed to give where I have labored and observed, are not, perhaps, in all their parts such as she teaches in other portions of the county. The crops and methods of cultivation which are most productive on one farm, may be unsuited to other lands. Therefore, you and I, probably, do not think and judge precisely alike. My views will be deemed erroneous. Be it so: suspect me, if you please, even of ignorance, partial observation, and visionary theorising. I'll bid the suspicion a cordial welcome, if by raising it, I can furnish you with a single fact or suggestion that may be turned to some good account. Cautioning you not to adopt my opinions any farther than they are approved by your own good sense and experience, I venture to notice, somewhat minutely, several of our common crops and operations.

Indian corn is one of the most important produc-

tions of our soil and skill. What varieties shall be cultivated? The early or the late?—The cold and frosts of '36 and '37, aroused almost every agricultural pen in recommendation of the early kinds; the tongues of Commissioner and address-makers were eloquent in their praise; and farmers generally became anxious to procure them for cultivation. The arguments of the many pens, the power of eloquence, and the more persuasive language of the prudent farmer's actions, could never, in my judgment, stand before a simple and unimposing array of facts and figures. During more than half a century the later corns have not failed in more than three seasons, to come to maturity in any ancestral fields. These varieties, I should judge, generally yield at least twentyfive per cent. more of both grain and stalks, than the early kinds. A very simple arithmetical process brings me to the conclusion, that there is little wisdom in abandoning the cultivation of the more productive varieties. It was a maxim with one, now deceased, who ranked among the best cultivators in my native parish, that he would rather have a crop of larger corn every other year, and a larger growth of stalks and green corn the intervening years, than an annual crop of small stuff. This maxim, in its spirit, if not in the letter, is perfectly sound. I have facts that seem to prove it. In 1837, when the corn was badly injured by frosts, I found by no neglect, if not by the most careful measurement of the crop upon one acre and ten poles of land planted with large and late corn, that it amounted to thirtyfive bushels that was quite well ripened, and thirtysix or seven frost-bitten and green; nearly half of the latter kind, however, dried sufficiently well to grind upon the cob and make tolerable food for cattle and swine. There were upon the farms earlier corns ripening well, and yet yielding a less valuable crop than the one described. This, let me be understood to say, was in the most unfavorable season, with two, or at most three exceptions, of the last fifty years. If in such a year the late corns make any thing like a near approach in value to the early ones, they must be decidedly the most profitable in the average of a succession of seasons. Making all the deductions which can be reasonably demanded for the greater exhaustion of the soil, and for a supposition that the early varieties with which I am acquainted are less productive than others that might be found, the position, in my mind, can and must be still maintained, that on all our good lands that are not cold and peculiarly subject to frosts, and where we intend to mature well and take proper care of our land, it is unwise to give up the productive for the early corns.

Which among the early, and which among the late varieties are best? I am but poorly qualified to answer the question. Can only say generally, that the dimensions of the kernel, particularly in depth, are worthy of much regard. The Dutton, in all its varieties, is no favorite with me. Its bright and sound appearance, the length and fullness of the ear, and its twelve rows recommend it to the eye, and it tells up well in the basket; but there is another meast-re—in the *half bushel* it is found

wanting: the cob-heap takes too large a share.—The eight-rowed ears, of the largest kernel that will mature in our climate, are to be preferred.—One of this description, under good cultivation, has not failed with us in any one of the last six years, to give a growth of at least sixty bushels to the acre, and has gone as high as ninetyfive. The proper name of this is not known, but in all respects, excepting color, it is like a variety of the Parker corn which I have seen. The Tuscarora has been considered as a garden corn merely. But the luxuriant growth of a small patch of it last year, led to a belief that it might be found profitable in the field; and I am anticipating a favorable result of an experiment with it. Here is a kernel that yields flour scarcely inferior in whiteness, softness, and flavor to the Genesee; and by the side of which the kernel of most of our corns is but a pigmy. I doubt not that on warm and good soils it will stand nearly at the head of corns in productiveness. Accounts are coming to us of a corn called the Brown, which in the high latitude of New Hampshire is made to yield an hundred, an hundred and thirtysix, even an hundred and fortyseven bushels to the acre. Doing so well at the north of us, I hope that some of our farmers will be induced to see how it will thrive in our own Essex soil.

Seed sometimes fails to germinate; worms and birds often make sad havoc in our fields. To guard against loss from these causes it is well to plant twice as many kernels in the hill as we wish to have stalks. There is a slight direct advantage in this: for the young plants, I know not why, grow faster for a few weeks in thick bunches, than when distant from each other. This method also enables you to dispense with all the sickly and unpromising plants, and retain a full supply of such only as are healthy and vigorous. The increase of product will amply compensate for the extra seed and labor of thinning.

Much has been written in praise of the famous Baden corn, yielding four and five ears to the stalk. We have been advised to select our seed from stalks bearing two ears, and thus make for ourselves a New England Baden. But I question the prudence of hearkening to the advice. Last spring a gentleman in Boston sent me three beautiful ears of corn, long, bright and sound; with a request to have them planted where they might have a good chance to show what they could do. The request was complied with. Subsequently I learned that they had been obtained by Badenizing a Canada corn, and that I might expect to obtain three and four good ears to the stalk. The ears are, I must acknowledge, uncommonly numerous, but very many of them are but small things, and I shall be disappointed if I find there as much good sound corn as would be obtained from five good stalks in a hill, bearing each one ear. I have for a considerable time thought that Baden's process would do little else than increase the pile of nubbins, or diminish the mow of stalks. This is merely an individual opinion, and is given without a desire that it should deter any one from making experiments.

I have some theories or whims to state, relating

to our treatment of the growing corn. Both air and light are thought to be serviceable to its roots; if so, it is a part of our business to keep the windows above them open. You have all noticed that rains and dews very soon form a slight crust upon the surface of our land in tillage. When this is formed, even but partially, it obstructs, somewhat, the passage of both air and light. In the short space of four or five days, be the weather ever so fair, the surface of the ground we stir, will become very considerably less pervious; passage ways should again be opened. But we cannot spend all our time among the corn. What then is our best mode of procedure? These subtle agents, if once admitted below the surface-crust, will move obliquely to a considerable distance; so that merely passing between the rows one way with the cultivator, may be sufficient for furnishing a temporary supply of light and air to all the roots. If so, the labor of passing through the other way should be deferred for a few days; then after an interval of a few more days, use the hoe. At the proper time, repeat the process. For thus, with an equal amount of labor, applied on nine different days at intervals of four or six days, your crop, if my theory is sound, will be considerably more benefited, than if the labor be all performed on three days, at intervals of a fortnight or more.

It is presumed that stirring the surface of the earth until later in the season than is usual with our farmers, would hasten the maturity and increase the quantity of our crops. I should confidently expect advantage from it up to the time when the corn becomes full. I speak of stirring the *surface*; and I mark the word as emphatic. Two years ago when thinning corn that was not more than six or eight inches high, I accidentally drew out the root of one stalk, that, upon measurement, was found to be twenty inches long. Afterwards, by pulling with care, roots much longer than I supposed that little corn possessed, were drawn out from many hills. Subsequent observation has confirmed the belief that the minute but important roots of our corn spread widely through the ground and that many of them lie near its surface. It is hardly necessary to assert that it is important to spare the roots of our growing plants. However minute they may be, the plant will suffer from the loss of them. The practice of ploughing deep between the rows, and making a high hill around the corn, must sever many of these roots, and lay the mass of them unnaturally deep in the earth. Corn thus treated is placed at disadvantage. There is no benefit whatever derived from making *any hill*. I have taken pains the present year to go through many fields, and notice the effect of every grade, from the level surface to the high hill, and I find no reason to think that the corn either grows better or stands better, for being hilled. In times of drought, the level surface will longer supply the corn with moisture, and will convey the rain, when it comes, more directly and abundantly to the thirsting roots. My conviction, that the surface of the ground alone should be stirred, leads me to refer to the instruments of cultivation. The plough is fast giving place to the cultivator. This exchange may be advantageous; but I am not satisfied that it is the best exchange that might be made. The form of the cultivator teeth does not suit me; it carries them too deep; they rend the roots of the corn too much. Many months ago, the query arose in my mind whether the size of crops which I had witnessed, was not augmented by the use of a *harrow* in

the cultivation. Since that time I have noticed with care such accounts as have come to me of large crops, and have been surprised to find that in most of the instances in which a very extraordinary yield had been obtained, the corn was *harrowed*.—I throw out these opinions in the hope that some one will be induced to bring any theory to the test of experience, and ascertain by some careful experiment the soundness or unsoundness of my conclusion.

One other topic in relation to this crop, demands a passing notice. If any faith can be placed in the testimony of those who have endeavored to ascertain the exact effects of taking the top of the stalk from the growing, or rather ripening corn, the farmers of Essex are not accustomed to pursue the best course. Experiment is said to teach, that when the corn, as soon as it has become a little hardened, is cut up at the root and shocked, the yield is greater than when left to stand with the stalk uncut until it is fully ripened; and that this latter method gives a larger produce than that of topping the stalk. The differences have been so great as to make the matter one of no small importance. Trials by measurement have never been made under my own inspection, but on each of the last two years I have seen the process of topping and cutting at the root performed side by side, and have no hesitation in giving a preference to the latter. The labor of harvesting by this process is believed to be somewhat less than by the other; the stalks as a whole are quite as good; the danger of harm from severe frosts less; and I doubt not that the corn is more and better. We all know that the other grains lose both in size and sweetness by drying upon standing stalks; and until experiments have proved the contrary, the fair presumption is that corn will do the same.

Grasses are usually forced to drag out a feeble and protracted infancy among the overshadowing and greedy grains. While delicate and tender as they can be and live, the screen is removed and they are laid bare to the scorchings of an August sun. That they so often survive the hardships of their situation, is matter of surprise. They would doubtless do better if sowed alone. I have no faith in the correctness of a common opinion, that they need something to protect them: they are the hardiest plants we cultivate; and the protection which the grains give, is too much like the wolf's protection of the lamb. Farmers, however, might not be wise in abandoning to any great extent, their accustomed course. The loss in one crop may be compensated by the convenience and worth of the other. Oats, as far as my observation extends, when luxuriant and suffered to ripen, are usually nearly fatal to the grass. The other grains are less harmful.

To some extent our grasses may be allowed to commence their growth under more favorable circumstances. Moist lands that will admit a smooth turning, may be easily and profitably renovated by ploughing in the month of August or September, applying a dressing of manure upon the furrow, sowing the seed, harrowing and rolling. I have seen enough of this method to recommend it in entire confidence that it is good. Where corn is cultivated without any hill, grass may be sowed among it at the last time of hoeing, to great advantage. One piece of ground laid down in this way, which has now been mowed five successive summers, has uniformly yielded a good crop and holds out better than any other piece of similar texture on which I

ever labored. Another piece from which two crops have been taken, does thus far equally well, and gives fair promises for the future. This method seems admirably well adapted to light and sandy lands, where grasses often fail to take root. The Hon. William Clark, of Northampton, who was the originator of this process, told me, according to my recollection, that he now often succeeds in obtaining two tons of clover to the acre on light soils, where no one had ever before been able to form, by the old process, any sward; and where it had long been deemed entirely useless to sow grass seed among rye.

The raising of roots for cattle and swine is yearly becoming more common. This is an improvement in our husbandry. Taking a succession of years, and a variety of kinds, roots may be raised at an expense of twelve and a half cents per bushel; perhaps for less. As aids in working off the coarser kinds of fodder, while the stock is kept in good condition; as means of increasing the quantity of milk, beef, and pork on the farm; and not least, as agents in enriching and increasing the manure heap, they fully repay the expense which obtains them. Taking both cost and worth into the account, perhaps neither the ruta бага, sugar beet, nor carrot, is to be preferred to the exclusion of the others. Let them all be cultivated. For milk cows, the sugar beet will probably be found the best; for horses and swine, carrots will be preferred. One winter's trial with two horses has proved that a peck of carrots per day is quite as good for a horse as four quarts of oats; when boiled, swine thrive well upon them. One eighth, and perhaps a larger portion of all the land which a farmer tills, may profitably be appropriated to the root culture.

Let not the advance and spread of total abstinence principles, cause you to set less value upon the orchard. Apples are worth as much for cattle and hogs, as they ever were for cider. Trial was made a few years since with two cows. One ate a peck of raw apples through a week; the other had none. The next week the apples went to the other crib. The third week the first cow again received them. Then came the second one's turn, and thus they went round. The milk from these cows was measured, and each peck of apples produced about one quart of milk.* For store swine they are worth at least half as much as potatoes. Apples will continue to be worth cultivating, even when all shall have ceased to stuffy the brain and sour the disposition by the use of cider; yes, even in the temperate times when the Trustees of this Society shall cease to offer a premium upon the best sample of an article that wars against the domestic enjoyments and thrift of many an Essex farmer.

(Concluded next week.)

Improvement in Agriculture.—It is encouraging to consider the great improvements which have been made in husbandry within the last quarter of a century, and the patriotic ardor evinced in the cause by our best men, who like the Roman Senators, are setting their hands to the plough, and exciting their neighbors to engage in this the most important of all arts, and the most conducive to the public good and private morals.

*This experiment, I am led to suppose, was not made with so much exactness as here described; but the experimenter was satisfied that the apples produced as much milk as stated above.

For the New England Farmer.

PLYMOUTH COUNTY AGRICULTURAL SOCIETY.

Report of the Committee on Improvements.

MR PRESIDENT:—The welfare of the whole community is very intimately connected with continued improvements in the art of agriculture. Increasing products of the soil are necessary to supply a growing population with food and raiment; necessary to furnish the means of prosecuting other arts in society, both useful and ornamental, and, as the principal source of that capital, which moves the commerce of a country, the branch of business which presents so many attractions to young minds. The motives of interest to engagement in this work seem very numerous and strong, yet enlightened and serious minds can discover higher inducements than any of mere temporal interest. In the labors and experiments of the field, we become co-operators with the great Author of all things: there we are continually incited to considerations of his doings and purposes, there we are abundantly blessed with the means of that acquaintance with our God, which will give peace, and all the good an immortal mind can desire. Notwithstanding all the inducements presented to labors in the field, it is often true that other branches of business obtain a very injurious ascendancy. Numbers of our citizens like some of the Israelitish worshippers, want a mass of gold immediately before them to stimulate their exertions; a promised land at some distance, though the assurances be repeated and strong, that it shall "flow with milk and honey," does not prove sufficient encouragement to persevering and laborious pursuit. Great haste is made to be rich. This circumstance has heretofore diverted the attention of many from some of the most important objects presented on your lists of premiums. Calculations seem to have been made, whether the amount of the offer would prove anything like a compensation for the labor and expense attending the proposed experiment. We hope more just and extensive views are now cherished, that competitors are generally seeking, and will receive better reward than our hands can give.

We have witnessed with pleasure an increased attention to the renovation of swampy lands; and some of the choicest treasures of this county have long remained useless and dormant in those situations. We rejoice to see the rigid bands broken, and banks of discount opening there. Claims to the premiums payable in 1840, have been entered by four persons, who in the accomplishment of their respective objects, will add a good number of acres to the productive fields in the county.

Three claims have been entered to the premiums offered to encourage the cultivation of nurseries of Chinese mulberry trees. Be not alarmed, sir, there is no furnace underneath to force the growth, nor any reckless speculator at your side, who would rifle your pockets by the influence of false representations; who would tell you that every bud in these nurseries, is of equal value with a five dollar bill; that the leaves of the tree are healing to every disease which afflicts the body; that they are convertible into a pleasant cheering beverage, and nourishing food; and that, what may not be required for those important purposes, can be manufactured into fine paper, on which you may write briefs.

The cultivators of mulberry trees in this county

have not been rash adventurers, and therefore will experience less temptations to resort to falsehood and imposition. Some of them feed worms proportionate to the increase of their trees. This we think the proper course, especially when the *Morus Multicaulis* are cultivated, for it is very doubtful whether those trees will ever be so acclimated here as to endure our winters.

We recommend the award of the first premium of \$8 to Mr Lincoln Jacob, of Hingham, who has cultivated a nursery of 2160 trees.

The second of \$4, to Mr Franklin Ames, of W. Bridgewater, who has 2150 trees—1771 more than reported last year.

We also recommend that two vols. of N. E. Farmer be given Mr Ames; and two vols. Yankee Farmer to Mr Benjamin P. Pratt, of Middleboro', who has a nursery of 1700 trees.

Priehard Stone, of W. Bridgewater, is entitled to \$9, having built the past season more than an hundred rods of stone wall. The same sum is also awarded to Austin Keith, of W. Bridgewater, Nahun M. Triban, John Wood and Isaac Pratt, of Middleboro'.

The committee in viewing stone wall, regard chiefly the sufficiency of it to protect fields against the inroads of cattle; but think the builders would do wisely in giving some attention to appearances, especially on public roads. The traveller will naturally conclude that fields enclosed with misshapen and loose walls, are no more than imperfectly cultivated. The ranges of wall built by Messrs Keith and Pratt, were distinguished for neatness in appearance, and we recommend that two vols. of N. E. Farmer be given to each of those persons.

In a country where there has been something of tillage more than two centuries, the farmer's success will depend very much on his attention to the operations of nature and his diligence in the collection and application of those vegetable substances and alluvial soils, which time is continually depositing in hollows, on the margin of forests, by the road-side, and wherever the course of the wind meets an obstruction. To encourage labors of this kind, the premiums which we have now to award were framed. The alteration from our former offers was not well understood by some of the competitors. In consequence of their misunderstanding possibly, the committee have been led into some errors. The arrangement in future years will be better understood. We think the alteration important and useful: we cannot think otherwise if we suppose there is any semblance of truth in what one of our orators said on a former occasion; that "in this county it is no uncommon thing for one town to blow into another."

The first premium for the collection of materials to enrich fields, \$20, we award to Galen Howard, of W. Bridgewater, who has collected 528 loads.

The second, of \$15, to Horace Collamore, of Pembroke, who has collected 344 loads.

The third, of \$12, to Alfred Whitman, of East Bridgewater—330 loads.

The fourth, of \$10, to Paul Hathaway, of Middleboro', and two vols. N. E. Farmer.

The statement of Mr Collamore was distinguished for particularity and we believe general correctness. We recommend that two vols. of Yankee Farmer be given him.

As this is a visiting committee, we may be justified in taxing your patience with a few excursive remarks. Every passing season presents to the

farmer numerous lessons which should be studied and applied. In a strong wind which passed over the country in the month of August, and prostrated so much of the corn, we were forcibly admonished of the impotence of providing some protection for the fields by planting trees on the borders. One field was passed after the gale, where the soil was bordered with trees on the north, and the corn in that field was standing almost perfectly erect. We could not suppress an emotion of regret that the efforts heretofore made by this society to induce the inhabitants of the county to plant trees on the road-side, had not received more attention. On the sea coast, raking winds are of more frequent occurrence than in the interior country, the injurious effects of them on plants and in the impoverishment of the soil, will be far greater where neither trees nor stone walls are standing as breakers.

We have been sorry to observe in many instances the remains of former wrong habits in tillage, in the erection of little mounds of earth round corn, potatoes and other vegetable plants. Ridge culture belongs not to New England, excepting when swamps are cultivated. In this climate there is seldom any redundancy of moisture, but often deficiency: our cultivation should therefore be directed with a view to the greatest retention in the soil of dews and rains.

In our circuits in the county, we have remarked a very prevalent neglect of fields in the last of the season. The strength of the soil, in many places, is more clearly exhibited in a rank growth of weeds than in useful plants. Weeds have the same forbidding aspect in the eyes of the farmer that vices have to the moralist. But the appearance is the least evil in the case: there is exhaustion of the soil and an abundant supply of seed to produce a future harvest of bitterness. We regard it important to direct attention to this subject, and encourage farmers to keep their fields clean of weeds as possible, through the whole season; still we are conscious this is one of the subjects on which preaching is easier than practice, and are willing to receive the application of the proverb in the full force that the appearance of our fields will justify—"Physician, heal thyself."

Respectfully submitted,

MORRILL ALLEN,
JESSE PERKINS,
JOSHUA EDDY.

Bridgewater, Oct. 16th, 1839.

For the New England Farmer.

THE KNOWLEDGE OF ENTOMOLOGY IMPORTANT TO THE FARMER.

MR COLMAN—The next department of natural science, which as he would succeed, (for success must depend on knowledge,) appears, in an eminent degree to demand the attention of the farmer, is that of entomology, or the science of insects. O how much the labors of husbandry are affected by small subjects, of which this kingdom of nature is composed! If an army of locusts visit Egypt, they consume every green thing, and a famine ensues. If an host of caterpillars after a night of peregrination, light upon our fruit trees, they exercise an influence which nought but the fire can rival. If the insidious borer finds its way into the choice shade tree, which, perchance, stands as a living memorial of the kindness of a friend, and may have received the nursing assiduities of years, its harsh gratings

may fall in cadence more mournful than the blast sighs through its branches, until the green leaf withers, and the outstretching arms fall bare, and the tall trunk decays. They commence their attacks upon our labors ere the seed has germinated in the earth, and continue not only while the tender blade is pushing itself upward, but they rob our foliage of its verdure, extract the fragrance from our flowers, cause our fruit to fall prematurely to the earth, and as "snugly as a mouse in a mill," they leave the rudiments of another generation with that which ripens, ready to spring with it into existence and become sources of vexations and disappointments when we look for wavy fields and luxuriant harvests.

Although insects are the source of much mischief to the farmer, they still have those among their clan possessed of redeeming qualities, and really act in subservience to his comfort and interest. Many of them, like ourselves, are carnivorous beings, and make their existence valuable by destroying those of a more feeble, but perhaps as the annoyers of man, a more calamitous character, as also those whose existence tends directly to his interest. Thus spiders not only feast upon other varieties of their species, but they weave the subtle web which proves the fatal net of many an unwary fly. The *Galeria Cereæ* is, unless efficient means are taken to prevent its invasions, in continual warfare on the honey bee. Even the little ants delight in warfare, and do not restrict their hostilities to other nations, but are hostile to those of their own who are guilty of differing from themselves in some family traits. In short, in every class, order, &c. of the insect nations, we find a system of warfare, a spirit of extermination, continually at work, not only upon other insects, and upon vegetable nature, but their ravages are carried to the higher order of things, and deposit their eggs so that generations may trespass upon the quiet and often become the murderers of the animals which holds as his particular friends, such as the innocent sheep, the ox on which he depends for labor, and the horse, given to strength and beauty,—and even man himself is subject to their invasions, for who has not been disturbed by the stinging of a gnat, the harpooning of a mosquito, or that most invidious of all midnight intruders, the gormandizing, blood-seeking, sleep-banishing bed-bug?

Now the department of science which embraces the insect tribes is exceedingly comprehensive. Will it repay in any way or shape for its investigation?

The wheat insect, which made its appearance a few years since, is annually destroying its thousands of bushels, and in many places its ravages are so complete, that farmers have abandoned the cultivation of the article it preys upon, and substituted those in place of it which are exhausting their lands and of course depreciating their value; in the mean time there has been a lack of breadstuffs in our country. Is it worth our while to search out the habits of this insect and stay its ravages? The latter cannot be effectually done without the former. Or is it best for us as an enlightened, independent people, to let it go on until some natural cause check its career, and independently buy our bread of foreign nations? If we rise as a nation to exterminate this foe, who are to be the chief warriors in the conflict? Will the physician leave the dying man, or the attorney his client, or the clergyman his desk, to sit as committee of investigation? No: their labors are in another field, while the farmer stands at the post of daily and hourly observa-

tion, and should be continually "taking notes" and "reporting progress" of the advancement or retreat of the common enemy.

It is so in other cases. An insect, a worm as is often the case, may attack his corn while yet the blade is scarce springing up. Its work of destruction does not move slowly and heavily along, but in the present state of things the remedy may be beyond his reach. Yet there was a time when a preventive was at his command, and perhaps he the fly as it hovered over the field, now and then descending and depositing its retinue of eggs which circumstances to which his own labors have contributed, have hastened to give up their living ones, his present relentless foes. Science, we say, a knowledge of these insects, might have remedied the evil.

The turnip fly, which annually occasions damage enough, which if avoided, would more than furnish those who sustain losses by its operations, with valuable works on this important science, has certain qualities which, if known, would make an easy victim to destruction; and it is so with the whole host of them.

The locust is a valuable tree, of rapid growth, and one which would become a subject of extensive cultivation, were it not for the borer, which under certain circumstances so fatally attacks it. These little engines of mischief do not stop their depredations with the spoiling of the tree on which their labors commence, but as sure as they destroy one, they will attack the many shoots which spring up from its roots, and thus they are transferred from place to place with the young trees, and will, unless destroyed, continue the work of destruction to the latest generation. Enlightened liberality has offered rich rewards for their destruction, but it has not slain the deadly foe; consequently, we may suppose that money, or even talents, unless directly applied, will never effect their destruction. Science, however, if placed in the hands of those who can take matter of observation when they lie down and when they rise up—when they walk by the way and when they sit under the green shade, will effect the object, and probably by some very simple process, perhaps nothing more than feeding the locustian with warm water instead of the rich juices of the tree. Indeed we have known them effectually destroyed by pouring boiling water into the orifice of their own formation.

But the destructive power of insects is not stayed by the maturity and death of the objects upon whose vitals they feed when the life-flood is in free circulation. They infest our granaries after the wheat has been separated from the chaff and is snugly stored away. They are among the first visitors to the flour barrel, when it has been placed where none but the good housewife should have access to its treasures. They devour the pine timbers of our buildings, when years have elapsed since the tool of the carpenter has given them their finishing. In short, the emblems of destruction have been scattered by them every where and about every object.

We certainly think there is much propriety, awe and necessity too, in the farmer's being an entomologist. Yet we would not advise him, like the English nobleman, to chase butterflies all day, (though we think his course quite as useful as that of some Americans, who put themselves in pursuit for whole days and nights, of those of their own species who, by every method that art can devise, affect to assimilate themselves to butterflies and va-

rious other insect tribes,) but to take the subjects of this part of nature's realm when and wherever he can find them, and never let them go until his acquaintance with their nature and habits has passed the ordeal of a thorough investigation. But there are new insects continually intruding themselves upon us. Of this we are well aware, and it is the privilege of those upon whose border they commence their depredations, like the men at Lexington, to give the first battle, and if the enemy are too powerful, to sound the alarm through the surrounding regions, and call their country's friends and theirs to their aid. Then night Hessian flies and the whole host of these marauders, like retiring Hessians, sound a retreat, and gladly forsake a country which offers no quarters to a common foe.

Mount Osceola, Feb. 6, 1840.

LETTER FROM HON. W. M. FOSTER,

Read at the Sixth Agricultural Meeting.

BOSTON, 17th Feb. 8 0.

MR COLMAN—SIR—Having attended with some profit, I hope, the various lectures of this lecture-loving city; but still, though old, desirous of knowing something more, I was induced by that insatiable thirst for knowledge which characterizes the present age, to attend two of your agricultural meetings, and there I found, as I expected, a display of the sound good sense of New England farmers,—knowledge springing from its native source—experience—tested by facts, and unadorned by any superfluous parade of science, or fanciful speculations.

I heard Mr Hill's very instructive lecture, and was carried by his glowing description of the great English farmer's establishment, (Mr Coke, of Holkham,) to the most pleasant period of my life, when I was something betwixt a farmer and a soldier—being obliged then to have my arms not far from my tools. It was in France, during the revolution, in the rebellious provinces, where I held lands, and had a family to protect.

Several topics discussed by Gov. Hill, brought to my mind analogous subjects, and the successful practice and ripe philosophy of my father-in-law, who was a large landholder and a scientific agriculturist.

However imperfect may be my recollection of events more than forty years old, and however small might have been my rural knowledge, I have thought that it might be of some use to call to memory what I can, and to offer it through you, sir, to the agricultural community, for I am convinced that the faintest hint, if it only suggest any thing new, will soon be brought to maturity by Yankee ingenuity. This fact I know, by experience, by the success of several mechanical improvements, which I have seen to grow out of mere hints of the practice in other countries, where the practice was far from being important, for the want of that proper application which has since been made of it by our intelligent countrymen. Some of these hints I gave myself, being an amateur of mechanics.

The Commissioner at that meeting spoke of the importance of making good butter, which, he informed us, might be made to command double the present price. So far as this article is the product of the soil, it must appear evident that no mechanical improvement in culture, or chemical improvement in manures, can be expected to offer a superior result, viz. doubling the net income.

The butter in and about Paris, is made and offered for sale without salt: it is put up in large casks, weighing several hundred pounds, and keeps perfectly sweet. I am not acquainted with the process of making this butter; for I lived in a province where the butter is no better than it is here, and often complained of it. But it is evident that the requisites above referred to, have been complied with in and about Paris, and the buttermilk is there thoroughly extracted, or the butter would not keep without salt.

I will now suggest a notion of my own, and one which I hinted at about twenty years ago, in one of the Boston papers. The buttermilk must be extracted, but the cream also must not be injured by being kept too long; and it would be better for neighbors who have small dairies, to unite with others, and make one churning before the cream could spoil.

Now to extract the buttermilk, we may take the mechanical process offered at the last meeting, or one, with a little alteration, which I shall respectfully propose, presently, to the inventor of the machine exhibited; and then borrow a little aid from chemistry.

I believe that salt will not mix, *chemically*, with a pure fatty substance, although butter may hold, *mechanically*, a large quantity of salt. With this hypothesis before us, and knowing that salt has a strong affinity for water and other rapid liquors, such as buttermilk, if we avail of this affinity, and present the strongest possible solution of salt, or strong brine to the buttermilk, the chemists will admit that the buttermilk will leave the butter, for which it has no chemical affinity, and go to the brine. So much will, I presume, be admitted. We will now return to the mechanical mode of separating the butter from the buttermilk. The plan proposed by the inventor of the *Fluted Rolling Cone*, is the right one; for the whole mass of the butter must be divided as minutely as possible, to extract *all* the buttermilk; for however little of it remains is a cause of injury to the butter: it is a fermentable substance, and from it may be extracted even alcohol; but the vinous fermentation is not so much to be feared as the acetous; for the butter itself is subject to that change, which makes it what we call rancid; and the *bombic acid*, thus produced, is one of the most subtle of poisons. So that rancid butter is, in a degree, poisonous. Now, although salt in quantities sufficient, is conservative, a small quantity aids fermentation; hence salt is good in manure, and useful to man and beast for digestion. It may have been the cause, also, of great mischief,—perhaps the yellow fever, which prevailed some years ago in our maritime cities, may be traced to locations exposed to the full south, where vegetable matter, partially salted, and washed by city drainings, at half tide, emitted the fatal miasma. This conjecture may gain some weight from the circumstance of the fever being found originally and principally in precisely such localities in Boston, New York, Philadelphia, Baltimore, Norfolk, and Charleston.

The alteration which I propose to make in the machine for extracting the buttermilk, is this. Make a tight box or trough, 18 inches by 12 and 6 inches deep: let a cylinder one foot long, 3 inches diameter, fluted or plane, be transversely fixed in this box, so as to revolve as near the bottom as possible, without touching it: this is to be turned by a wooden crank, and the box to be kept full of strong brine; the butter being placed on one side

of the cylinder, and pressed down, while the crank is turned, will come out on the other side, in layers as thin as paper: thus the smallest globules of buttermilk will be immediately extracted. Now if I be correct in my philosophy, this butter, although minutely exposed to a strong solution of salt, will come out fresh; and will require salting if salt should be required.

The process of whitening wax is somewhat similar; it is reduced to the thinnest sheets, and then exposed to the action of the sun and air. Perhaps those who now raise beeswax, or bayberry wax, might at their leisure hours, add fifty per cent. to the value of these articles, by whitening them at home. I see by the price current that yellow wax is quoted at 30 cents, and white wax at 50 cents.

If, sir, you should find the hints in this letter worthy of notice, and should wish it, I will offer to your consideration some remarks on forest trees, the importance of keeping the high lands always wooded, and the mode of covering those which are now denuded. Also, on the choice of seeds of domestic growth; manures, and perhaps some peculiarities of European practice, which have been considered of little importance, and so familiar to their writers, that they have not been noticed in their books; yet out of which Yankee ingenuity might make something.

Very respectfully, your obt^d serv^t,
WM. FOSTER.

For the New England Farmer.

MR. EDITOR:—Observing in the N. E. Farmer of the 19th instant, a communication from one of your correspondents on the subject of raising the Rohan Potatoes, I have been induced to send you some facts in regard to my own experience in that way.

Early in March, 1838, I purchased at the Office of the N. E. Farmer, one box of Rohan Potatoes, and taking it home, divided the contents with a neighbor, at whose instance the purchase had been made. My moiety, consisting I believe, of four tubers in number, and those of rather inferior size, was planted in hills, in a rich mellow soil, some time during the month of April following. They were well manured with manure from the stable, and so divided on planting, as to make from the same four tubers, (if I rightly remember,) some twenty hills, yielding on harvesting, at the rate of twelve hills to the bushel: which, as the season had proved very unfavorable on account of a severe drought that prevailed, was considered an extraordinary good yield. At all events, it exceeded that of the long red potato (the most prolific root of the kind cultivated with us, and planted by me this year, under circumstances equally favorable) about one third; twelve hills of the former, as just stated, affording a bushel, and eighteen of the latter. This result told much for the Rohan Potato, and so disposed me to think favorably of it, that it was with great regret I felt compelled afterwards, to admit concerning it, what on subsequent repeated trials proved but too true; namely, that however valuable it might be deemed on account of its superior productiveness, it was not entitled to be so esteemed on account of its edible properties. For the table it was pronounced decidedly inferior to any other variety known. Still, if it was found to yield a much greater crop with the same expense of cultivation, as the foregoing statement would seem to show, this undoubtedly

was a redeeming property of paramount consideration.

Accordingly, in order to be more fully satisfied on this point, I last spring (1839) planted this potato in the same field, and side by side, with the long red above alluded to. Both kinds were planted at the same time, and subjected to the same mode of treatment; the whole course differing in nothing with respect to the two, except only in one particular, and that was in regard to the quantity of seed used. The former were cut into small pieces, of which two, each containing perianth one eye, not less, were placed in a hill; whereas, the latter were planted entire and without being cut at all, the number of tubers to a hill being varied from one to two, according to their size. The result was, that the yield of the rohan compared with that of the red, was very nearly the same with that of the preceding year, (1838) namely, as three to two. In this case it may be proper to observe, that the ground upon which these roots were grown, had been, in 1838, in Indian corn, and was manured for the potato crop of the last year, with a good compost from the barn yard, which was well spread and harrowed in previous to planting.

At another place, and in a soil better adapted to the production of the potato, it being a deeper and richer loam, I also planted, last spring, about twenty rods of ground with the rohan, cutting it as before described, and manuring in the hill, with one shovel full to the hill, with manure taken from the log-yard; the hills being about four feet distant each way. This piece was hoed twice, and harvested (if I rightly remember) sometime in the early part of October. The yield here was superior to that in the other field; the best part of the piece affording one bushel from every six hills. The potatoes produced on this and on the other piece of ground, were of large size, some tubers weighing two pounds each.

Such, Mr Editor, as nearly as I can present them from memory,* are the principal facts connected with my attempts to raise the Rohan Potato, concerning which so much has of late been written. And if it be said of the foregoing statement, that it does not evince an exactness and particularity of observation, and a carefulness of comparison, such as ought to characterise all experiments of a similar nature, especially when conducted with a view to establish important practical results, I certainly should not undertake to vindicate it from the charge. It must go for just what it is worth, nothing more. What then is the legitimate inference deducible from the state of facts above presented? It is, so far as they go to establish any inference, that the Rohan Potato, under precisely similar circumstances, and in the ordinary way can be raised on any given quantity of land, in greater abundance and at a far less expenditure of seed, than can be obtained from the most prolific of the ordinary kinds usually cultivated among us. Assuming, therefore, and it may be fairly done, that, in point of nutritive properties, considered as food for stock, this root is, not to say the least, *inferior* to the common kinds, and it must be viewed, if the above conclusion be correct, as an acquisition of no small importance to the agricultural interest of the state.

Yours,

J. E. HOWARD.

West Bridgewater, Feb. 22, 1840.

*I did not take any minutes at the time, and, consequently, have no written memoranda to refer to in the case, which I regret.
J. E. H.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, MARCH 18, 1840.

OBITUARY.

Died on Wednesday last, JOHN LOWELL, Esq., of Roxbury, aged 70 years.

Obituary notices are foreign from our general practice; but it would be a signal ingratitude for the New England Farmer to pass over without notice the departure of this excellent man; one of the founders of this paper; while health permitted, one of its most liberal and instructive contributors; and a gentleman, to whose intelligence, activity, public spirit and liberality, the agriculture of Massachusetts, for any improvements it has attained, is perhaps more indebted than to any other individual, living or dead. We can do but very imperfect justice to his elevated character; and no language would be exaggerated in expressing the unmingled and profound respect with which we have always regarded him. He was, indeed, an honor to human nature.

Mr Lowell was born at Newburyport, and came to Boston early in life with his father, the first judge of the District Court appointed by Washington. He entered college at twelve, and became a practitioner at the bar before he was twenty-one years of age. He came at once in competition with the eminent men of that period—Dexter, Parsons, Ames, Gore, and Sullivan, composing an extraordinary galaxy of learning and talent; and in spirit and activity, in legal learning and acquirements, in quickness of perception, in address, in fidelity to his client, and above all, in a character for integrity and honor, he held a rank at the bar second to none. Immersed in a flood of professional cares and labors, which were quite too much for his excitable and active temperament, his health became greatly impaired; and at the age of thirty-five, when in general other men are just beginning to find their foothold in the profession, he retired, and went to Europe for the restoration of his health. After an absence of three years, he returned to the country; and without resuming his professional business, he gave the energies of his enriched and active mind, his time, his services, and the powerful influence of his character to every object of a public nature, in which he saw an opportunity of serving the public welfare.

From the accession of Mr Jefferson to the Presidency to the close of Mr Madison's war, politics were the engrossing theme; and his contributions to the public press were immense and incessant. They were always recognised. They were universally read. They were remarkable for their fullness of, and familiarity with, facts; for their boldness; for their extreme severity without any coarseness; and for the pungency and closeness with which he treated every subject which he discussed. With whatever severity he might write, no man was ever farther than he from making willingly any misstatement or exaggeration; and no one was ever more candid and just towards his adversaries. Few communications ever addressed to the public through newspapers or in a pamphlet form, probably ever had more influence upon public opinion than these. Though a zealous politician, no one could be more disinterested. At one time Mr Lowell represented the town of Boston in the General Court; but excepting this, he neither sought nor would accept any public service, or any political trust of profit or honor whatever.

The finances of the town of Boston being at one time in some measure embarrassed and confused, he at once effectually exerted his influence to introduce system and arrangement, under which they were recovered; and the

beneficial effects of which are felt to this time. The foundation of a general Hospital and a Hospital for the insane becoming then matter of interest, Mr Lowell may be said to have taken the lead in this humane project, and in laying the foundation of this distinguished monument of public liberality; and devoted his time, talents, money, and especially the powerful influences of his ardent mind and character to this object, with signal effect. The controversy then arising, which led to the great division of our churches, Mr Lowell, as a layman, came out with great eloquence and power in behalf of the rights of conscience, of free inquiry, and private judgment. The Institution for Savings, which has done more for humanity and good morals than almost any institution among us, and the Athenæum, among the brightest honors of our city, are largely indebted for their foundation and success to his intelligent and liberal exertions.

During this time he had been appointed one of the corporation of Harvard college—a situation which he held for many years; and as such, no one could be more distinguished for his punctuality, assiduity, and devotedness to the best interests of the institution, or have done more for its honor and usefulness. Through this whole period Mr Lowell had resided for a considerable portion of the year, on his farm in Roxbury, which he inherited from his father; and had given the most enlightened, exact, and practical attention to the farming pursuits of gardening and an improved agriculture. He had been a long time a member of the Board of Trustees of the Massachusetts Agricultural Society; for some years one of its Secretaries; and for several years its President—always active, prompt, liberal, and efficient, until declining health compelled him to retire from all public duties.

He rendered very eminent services to horticulture and agriculture. No man had a juster appreciation of the importance of these arts to the general welfare and comfort of the community; and with his enthusiasm of curiosity in respect to physical science, his extensive inquiries into the varied branches of knowledge, his refined and cultivated taste for the beauties and charms of natural scenery, added to an honest conscience and a mind unclouded by avarice or ambition, no man could enter with a stronger relish into the pure and delicious satisfactions and pleasures of rural pursuits.

Besides taking the lead for years at the agricultural shows at Brighton, his communications on agricultural and rural subjects to the public through the Massachusetts Repository, the New England Farmer, and other publications, were numerous and highly instructive; possessing not an ephemeral but a permanent value. His careful journals of the seasons and the progress of vegetation, continued for a series of years, have been annually looked for by the public with strong interest. He was eminently instrumental in introducing several new and useful articles of culture, and some of the most valuable fruits which are known in the vicinity of Boston; the seeds or sown of which he always distributed in the most liberal manner. In the introduction of improved breeds of cattle, horses, sheep, and swine, and improved implements of husbandry, and in extending the knowledge of improved modes of cultivation; and especially in seeking to elevate the character of the art by improving the character and condition of our husbandmen, and to lead the public to a higher estimation of agriculture as a liberal pursuit, no man has ever labored with more zeal or efficiency.

Mr Lowell, on account of declining health, had been for some time retired from general society; and has at last obtained his release from this scene of trial and labor in a way which a truly philosophic and good man would most desire—suddenly and without pain. He died while reading, in his chair. He has left a character which his

children and friends will cherish as the richest legacy in this case that heaven could have bequeathed to them. Mr Lowell's mind was of the highest order, and remarkable for the quickness of its perceptions, the comprehensiveness of its views, and the soundness of its conclusions. His temperament was exceedingly excitable; and when engaged in any object of public interest, he kindled with enthusiasm, and his whole soul showed itself in his eyes, his words, and his actions. Other susceptible minds brought into contact were at once brought into sympathy with him; and thus always rendered his society delightful. His conversation was always full to overflowing, and distinguished not more for the copiousness of its utterance than the fulness of his thoughts. His activity, promptness, and perseverance in whatever he undertook, were eminent traits of character; and he shunned no labor, warfare and whenever he had the power to do good. In his manners he was distinguished for his urbanity, his accessibility, his simplicity, and perfect freedom from ostentation; and though from his talents and temperament he was always in the foreground in whatever society he mingled, yet it was evident no man ever thought less of himself as a leader. While he assumed for any object to which his mind and energies were devoted, all the importance which belonged to it, and to others it might be obvious that it was mainly effected by his personal exertions, yet no one ever assumed less for his own agency. Like the highest moral rank of minds, to which he belonged, he entirely lost sight of himself in view of any great object of social improvement, of usefulness and humanity. But what above all things was the crowning glory of his life, was his integrity; his clear and inflexible perceptions of moral right; his lofty and profound sense of duty; his honor, liberality, magnanimity and disinterestedness. We do not use these terms without meaning. In their highest sense were they applicable to the lauded subject of this imperfect notice. We have no hesitation, from a long observation and knowledge of his character, in pronouncing him one of the most intelligent, useful, and excellent men that ever adorned our community; and in saying, without disparagement to any one, that he has not left his superior.—We bow in humble submission to that solemn but mysterious mandate, which has removed him from among us. We may truly say of him here that he has come to his grave like a shock of corn fully ripe in its season. We cannot doubt that a mind so bright and a heart so pure, has been translated to a sphere more congenial to its purposes and affections, to diffuse a wiser and more beneficent influence than it could exert here; and that a life like his, of honor, integrity, usefulness, and beneficence, under the government of God, cannot fail of rewards corresponding to all our reasonable hopes and to our purest and best desires.

H. C.

NINTH AGRICULTURAL MEETING.

The Ninth Agricultural Meeting was held on Thursday evening, 12th inst. at the Representatives' Hall, Mr King in the chair. The attendance was quite full. The subject announced for the evening was the Silk Culture, and several gentlemen from other States attended the meeting.

Mr Timothy Smith, of Amherst, who came as a delegate from the Hampshire, Hampden and Franklin Agricultural Society, brought with him some beautiful specimens of raw silk, of sewing silk, and of lutestrings, the silk raised by himself and the manufacture done at Northampton.

Mr Benedict, likewise, of Pawtucket, R. I., exhibited some remarkably fine sewing silks.

The Commissioner presented some beautiful sewing silk, manufactured at Harvard; some splendid ribbons of various patterns and colors, and some silk velvet, the production from the worms, of Miss Gertrude Rapp, of Economy, Penn.; and some beautiful specimens of raw silk

from Dr J. Deane, of Greenfield, Mass.; and a specimen of raw silk from Mr. Cheney, of Burlington, N. J.; and samples of extraordinarily fine coccons, from Mr. Avery, of Brooklyn, Conn. These two last were from worms fed on the leaves of the *Morus Multicaulis*, set out the last spring.

The general objects of the meeting having been stated, and some history of the early introduction of the silk culture into N. England, the way was opened for some experimental and practical statements from Mr. Smith, of Andover, Mr. Sharp, of Chaplin, Conn. (formerly part of Mansfield,) Gen. Amory Holman, of Bolton, and Mr. Benedict, of Pawtucket, R. I., all of whom had been engaged for a length of time in the production of silk; and some inquiries and discussions in relation to the profits and prospects of the silk culture in New England, and the general importance of the subject, on the part of Mr. Dodge, of Hamilton, Mr. Davis, of Webster, Dr. Graham, of Northampton, and others.

Our reports of the statements and conversation, it will be seen from the state of our columns, are necessarily postponed.

H. C.

A CARD.

The Commissioner of Agricultural Survey has the pleasure to acknowledge the receipt of a model beehive, of approved construction, from Mr. John Sholl, of New York city, apianian, which he will have the pleasure to exhibit at the next agricultural meeting. Mr. Sholl is a thorough beehive master, and has given great attention to the subject. He is likewise the agent in this country for Nutt's celebrated beehive, one of the most beautiful erections which can adorn a garden. This hive goes upon the only righteous principle, that the laborer is worthy of his hire, and has the first claim to the fruits of his toil; and not upon the highwayman and assassin principle of either starving the laborer, after the fashion of Ireland; or, in defiance of all justice and humanity, putting him to death and then plundering his honest earnings—a principle of political economy if not carried to the extreme, yet but too often acted upon to a considerable degree in other communities than those of the bees.

He likewise acknowledges the receipt of a "Manual or Easy Method of Managing Bees," from Mr. John M. Weeks, of Salisbury, Vt.; full of excellent instruction, and an improved edition of which is now in the press of Weeks, Jordan & Co. Mr. Weeks has made himself familiar with the various and important details of these insect instructions, and has the most respectable and useful folk; and has invented a hive, which is highly commended wherever it has been used; and which is used upon the just and benevolent principles above referred to. He has promised the Commissioner a model of his hive, which when received, he will be happy to exhibit to his agricultural friends.

Disdain as much as we please the labors of these humble operatives, there is not a doubt that, under proper management, they might be made to produce a revenue of millions of dollars to the country, besides leaving them enough of their own produce for their own subsistence. A single hive this very last year, has given to its owner, (if our abolition friends will allow us to speak of an ownership of these industrious laborers, who are excellent mortals are continually putting to shame the indolence and improvidence of mankind,) of more than one hundred pounds; and this honey being free from bread and inclosed in neat glass boxes, commands in New York market fifty cents per lb. The previous year, we understood from an amateur apianian, that he took 124 lbs. from one hive.

The Commissioner acknowledges, likewise, a sample of Indian corn, called the *Ponroy* corn, from Messrs Ellis & Bosson, of a valuable variety; and another sample of corn from the Messrs Hovey, of extraordinary excellence, to judge from the accounts given of it, and its appearance, as will be shown, of four good ears on a stalk, which is stated to be common in the field.

He has likewise to acknowledge a second sample of butter of the finest description, from the farm of Mr. Geo. Denny, of Westboro', (the former having been distributed among our agricultural friends,) made from cows fed upon carrots and hay. For winter butter, we believe its quality cannot be exceeded; and the manner in which it is brought to town hardly admits of improvement. The best of June butter rarely exceeds it. This butter may be seen, we believe, once a week at Bishop & Bard's provision store, corner of Howard and Court st.

Mr. Denny has found upon trial, that the butter made from the cows when fed on sugar beet, is inferior both in color and quality to that made when the cows are fed upon carrots.

HENRY COLMAN,
Commissioner of Agricultural Survey.

TENTH AGRICULTURAL MEETING.

The tenth Agricultural Meeting will be held on Thursday next, at 7 o'clock P. M., at the Representatives' Hall. The subject, Root Sugar, and the cultivation of vegetables for Stock.

Mr. Teschemacher, and Mr. D. L. Child have engaged to address the meeting. We hope, likewise, to hear from Mr. Bosson, who went to France under the patronage of a liberal subscription, to possess himself of the latest and most authentic information on this important subject at the fountain head.

H. C.

MASS. HORTICULTURAL SOCIETY.

FRUITS EXHIBITED.

Saturday, March 7, 1840.

Mr. N. Whall exhibited Royal D'Hiver and L'Echassarie Pears.
Mr. Oliver—L'Echassarie Pears.
Mr. Wright—Cattilac Pears.
Mr. Downer—Roxbury Russet, Gold & Russet, Wales and Royal or Old Pearmain Apples, Iron Pears. Among Mr. Downer's Apples were some very fine specimens.

For the Committee,

E. M. RICHARDS.

BRIGHTON MARKET.—MONDAY, March 16, 1840

Reported for the New England Farmer.

At Market 315 Beef Cattle, 20 pairs Working Oxen, 20 Cows and Calves, 615 Sheep and 340 Swine.
Pigs—*Beef Cattle*.—The prices obtained last week for the best qualities were hardly sustained. We quote a few extra \$7 00 First quality, \$6 75 Second quality, \$6 50. Third quality, \$5 30 a \$6 00.

Working Oxen—We noticed the sale of a few yoke, \$75, \$80, and \$110.

Cows and Calves—"Dull" \$23, \$26, \$29, and \$38.
Sheep—Lots were sold at \$3 25, \$4 00, \$4 75, and \$5 00. A few fine Cusset or others at about \$10 each.

Swine—Several lots were sold on Saturday at 5 for sows and 6 for barrows. At retail 6 for sows and 7 for barrows.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northernly exposure, week ending March 15.

March, 1840.	7 A. M.	12 M.	5 P. M.	Wied.

FRUIT TREES FOR SALE.

A good collection of Apple, Pear, Plum, Cherry and Peach Trees, for sale at the Pomological Garden, Salem, Mass. Salem, March 15, 1840. ROBERT MANNING.

BOX FOR EDGING.

JOSEPH BRECK & CO. have for sale 500 yards of Box for edgings, in prime order; price 374 cents per yard; every yard will make two when reset.

Giant and Early Wilmot Rhubarb

Roots of extra large size at 25 cents per root, for sale by JOSEPH BRECK & CO.

Asparagus Roots.

Large transplanted Asparagus Roots, for sale by JOSEPH BRECK & CO. Also—Strawberry Plants, of approved sorts.

PUBLIC AUCTION.

The subscriber having leased his Farm near this city, will offer for sale, on sat. forenoon, on Wednesday, the 25th day of March inst. all of his valuable stock of neat Cattle, being about fifty head, mostly high bred animals, among which is one full blooded Durham Bull, four years old, from the stock of Col. Powell, of Philadelphia; ten or twelve Cows; three very fine yoke of working Oxen. The remainder young stock, very fine.

Sale positive and terms liberal. If the weather should be stormy, the sale to take place the first fair day.
Hartford, March 11, 1840 JOSEPH MORGAN.

BOX.

For sale at the Garden of SAMUEL DOWNER, in Dorchester a small lot of tall Box. Also, a large lot of short box, with fine roots and will make a neat border.
March 11. 31

MISCELLANEOUS.

THE MONKEY.

DEAR Brother of the wood!—I hail
 Your likeness! (Oh! except the tail!)
 When swarming from thy cocoa tree,
 The nimblest of "Jack tars" we see!
 And when curled up upon a rock,
 Like person peering in his back,
 Art thou descendant of poor Cain,
 Who took "the curse"—for Luther slain?
 And had impressed upon his brow,
 "A mark"—that all the world should know.
 Beyond a doubt thou art the same!
 Memorial of the murderer's shame!

And yet, in thee, much wisdom is!
 Altho' the world salute with hiss,
 I saw thee cure when sailor dazed,
 To pinch thy tail unseasonably hard,
 Catch up a ball of "spun yarn," and
 Upon the yardarm—take thy stand!
 Till "Jack," forgetting thy affront,
 Stood just below: (his own his wound.)
 When down upon his head there came
 The ball—*as comes the lightning's flame.*
 While on top gallant most secure,
 Thou clattered at his face demure!

Thou art the prototype of man!
 When Heaven first pronounced his ban;
 And now, thy race is often seen,
 Tripping with daisies on the green;
 A little sick to hand, and hair,
 Curling about his visage fair!
 The tail—tucked in his overalls;
 The ears, his cap above them fills;
 The beard shaved off his dimpled chin;
 But all the monkey—strong—*action!*
 Tobacco swells his lily rolls—
 The same as *thine*, when eye o'ersails;
 And all the difference in the "daily,"
 That thou drink *milk*, and he drinks *brandy!*

From the Farmer's Cabinet.

NUTRITIVE MANURES.

It is in the observation of every man, from the most illiterate to the most enlightened, that all kinds of animal substances, when thoroughly digested and corrupted, are the strongest and most powerful promoters of vegetation. The hair, the skin, the horns and hoofs, the urine and excrements, the flesh, blood, sinews, and even the bones, are all richly replete with matter which supports and invigorates vegetation universally. It is therefore undeniably certain that animal substances contain those principles which are the real and genuine food of plants. It is absurd, therefore, to suppose their food is earth, or water, or air, fire, or heat, or any one or single simple element or thing whatever. It seems clearly evident, that it is a combination of principles derived from animal substances by the chemistry of nature. When an animal substance has been thoroughly purified, almost the whole becomes volatile, and is so far attenuated, subtilized and refined, as to be rendered capable of entering the roots and fibres of the minutest plants.

It seems then, that as the animal kingdom is entirely supported by the vegetable, so is the vegetable by the animal, and each is reciprocally the support of and is supported by the other. The matter of each is essentially the same; each is endowed with the principles of life and augmentation, though appearing under very different forms; each mutually transmutable into the other by the mere unassisted operations of nature.

To this theory it may be objected, that vegetation may be successfully promoted by vegetable manures, without the least assistance from animal substance of any kind. Every one knows that it is

common to manure the ground by ploughing in green vegetables, such as buck-wheat, clover, &c., which often succeed well without any other help whatever. This objection falls short of its object; it only proves that profitable crops may be obtained without the cultivator's using animal substances under that form; but the theory supposes that every vegetable is replete with principles derived from animal substances, and only differs from them in being more subtilized and refined.

It is equally certain that vegetation may be profitably promoted, without haying or providing any manure at all. The horse-hoeing system of husbandry depends entirely upon reducing and pulverizing the soil. It cannot be reasonably supposed, however, that the spade and hoe, or plough and harrow, or cultivator or scarifier, convey any fertilizing principles. These operations which are found to render our lands so surprisingly fertile when judiciously performed, only prepare the soil for the easy entrance of those fertilizing principles with which the atmosphere is abundantly replete. The atmosphere is the grand magazine, the great receptacle of putrid exhalations, which incessantly fly off from all animal substances, the living as well as dead; and by their specific levity mount up into the air, from whence, being condensed, they return in dew, rain, snow, &c., and impregnate the soil as deep as it hath been duly pulverized.

"MUCH ADO ABOUT NOTHING."

"Nothing extenuate!"—*Shaks.*

Gentle reader, did you ever think of *nothing*? Your reflective faculty is not questioned; a mind will often think of *nothing*. *Nothing* pre-existed matter; yet *nothing* is new. *Nothing*, therefore, hath immortal youth. We can entertain the annihilation of *nothing*; and yet, it is said, we have the fullest assurance of the existence of *nothing*. Much has been written, said, and sung about *nothing*; and yet the world is ever slow to admit it knows *nothing*; truly, it fully comprehendeth *nothing*. I have pondered *nothing*, *nothing* more deeply than truth and duty. I have not thought I thought, (as is the case with most who ponder *nothing*;) but known I thought till I knew *nothing*. The fool knoweth *nothing*; the wise man knoweth that he knoweth *nothing*. I once heard it sagaciously remarked, that an eloquent preacher had "proved *nothing*," who proved that *nothing* was more evident than the indispensableness of religion. Skeptics believe in *nothing*; and believers hold *nothing* more essential to human happiness than Christian truth. The labors of many philosophers have established *nothing*; and science has sought *nothing* more than truth. The geologist gravely tells us that *nothing* which his researches have discovered is at variance with revealed truth, and the Mosaic account of the creation. *Nothing* causeth much mirth, and *nothing* often draws tears. *Nothing* is more coveted than wealth; yet *nothing* is more uncertain. *Nothing* is more urged in the pulpit than piety and devotion; yet *nothing* more needs to be urged. *Nothing* is more evident than the distinction between legality and equity; yet *nothing* is less insisted on. *Nothing* is more certain than the relation between cause and effect; yet *nothing* is often accomplished. Some love *nothing*, and are loved by *nothing* in return. (This is reciprocal attachment!) *Nothing* is deified: some worship *nothing*. Notwithstanding the crying sin of selfishness, (think, I pray you, of a sin crying! favorable omen, surely!) *nothing* is more common; yet, *nothing* is more rare than true Christian philanthropy. *Nothing* embitters life more than envy, jealousy, and strife; yet *nothing* promotes self-sacrifice, confidence and peace, more

than inward purity and rectitude. *Nothing* is the cause of more misery in social life than unreasoned passion, ill-considered attachment, and imprudent marriage; yet *nothing* assures of more bliss than the purest, most virtuous, self-forgetting love, and sympathy. If we ask any of the many repining and discontented, the cause of their misery, the answer will be, "*nothing*;" and, truly, *nothing* which dwells in the world around them is the cause. The man of learning prefers *nothing* to his books; the lawyer, *nothing* to his fee; the merchant, *nothing* to his gains; the votary to sense, *nothing* to his pleasures; and the Christian, *nothing* to his faith. Some spare *nothing* to compass their ends; though the guilty stop at *nothing*. He who is content, desires *nothing*; yet he who hath *nothing*, is not content. In the competition for the prizes of life, *nothing* is often obtained, yet *nothing* satisfies; still, he who loses *nothing* is fortune's favorite. Many have *nothing* to stimulate them to action, and *nothing* as the object of their being. *Nothing* may be found by those who seek; though *nothing* will be the reward of the indolent and negligent. *Nothing*, in fine, will be lost, if we hold fast to our integrity; and *nothing* is more enduring than power of mind and uprightness of purpose. Reader, what is *nothing*? Iago saith it is money—"Who steals my purse," etc. Yet, I desire to be persuaded of *nothing* more than this, Where is *nothing*?

"Where begin
 The suburbs of creation! Where the wall
 Whose battlements look o'er into the vale
 Of no existence? *Nothing's* strange abode!"

In thy mind is, most patient reader, and in mine
 hath been *Nothing*.

PEACH TREES.—One of our best fruits is the peach, yet it is very little cultivated in Massachusetts, except in the immediate vicinity of Boston. The tree requires different treatment from any other. It is subject to injury from the borer. This may be prevented by a free use of ashes, especially that of anthracite coal round the trunk. Its tendency is to run up like a maple in a swamp, and if left to itself it becomes in a few years something like a scraggy hop pole with a cabbage head on the top of it. This may be prevented by heading it down when first transplanted from the nursery. The second year it will be a spreading tree. To keep it so, cut off all the weak shoots and continue to head down the strong ones, moderately, as long as it makes new wood vigorously. I have trees treated in this manner, which have been in full bearing ten years past, without failing one season during the whole time. The peach is trimmed, I think, to the best advantage in February or March.—*Exchange paper.*

BOOK FARMING.—A correspondent of the Farmer's Cabinet says—"Many farmers set their faces against agricultural newspapers, and utterly discard all improved implements of culture. This is not right. Those who oppose these means of improvement, fight strongly against their own interest. I am free to confess that I was once set against theory and book farming, but since I became a subscriber to your publication, my views have not only changed, but the aspect of my land has changed, and that much for the better."

N. E. FARMER.

AN ADDRESS

Before the Essex Agricultural Society, at Georgetown, Sept. 26, 1839. BY ALLEN PUTNAM, of Danvers.

[Continued.]

Manures—the means and methods of increasing and compounding them; the particular soils and crops to which each kind is best adapted; in what state and at what seasons they should be applied; these all claim our careful attention and close study. Knowledge of these is the main-spring of improvement and success in husbandry. Attempting to farm without manure, is like setting up to be a gentleman of leisure and fashion without money. The thing wont go. The proper construction of yards for cattle and swine; the advantages of a cellar under the barn; the more common means of increasing the manure heap; I have no time for considering. Important as brevity is however, the claims of muck to our regard must not be passed over in silence. Many of our swamps and meadows consist of an invaluable collection of decomposed vegetable matter. This, by a few months exposure to the atmosphere, becomes an excellent material for making most valuable composts. I am persuaded that its worth, and the best methods of using it, are not generally understood. A highly intelligent member of this society, recently invited me into his fields, and I have seen but little corn of fairer promise any where, than was growing upon land broken up the present season, because bound out, and where the only dressing used was fifteen or sixteen cart loads of compost to the acre; three fourths of which was meadow mud, the remainder stable manure. Another of our members, intelligent and scientific, has a fine field of corn manured with meadow mud, mixed with quantities of stable manure and wood ashes so small as to make the whole an uncommonly cheap dressing for that crop. This field, perhaps, will teach some valuable lessons. I say no more, because, its owner will undoubtedly be the willing organ of its communication with this society. Unmixed with any other ingredients, this swamp mud, after being rendered friable by the frost, is a very considerable fertilizer of light soils; and will well repay the expense of using it as a top dressing upon grass lands. I will here remark that the meadows, in which good muck abounds, are among our most productive soils and most profitable for cultivation. The necessary draining may often be accomplished while one is obtaining muck for the manure heap. Where there is sufficient consistency for the use of the turf-spade, and where a new ditch is to be opened, this labor may conveniently be performed in winter, when the meadow is so firmly frozen as to make it convenient and easy removing the mud to the upland. This is no mere theory. These feet and these hands know to the full extent, what there is of cold and discomfort in working in the muddy ditch

on days that do no discredit to January; and they will tell you that when cased in boots and mittens they will not ask for a more comfortable place. As far as the farmer has opportunity to collect materials for his manure heap, and drain his wet lands at his most leisure season, prudence directs him to embrace them. But my subject is manures. Chaptal, in his Agricultural Chemistry, says that "the excellence of a soil depends upon its containing the right proportion of each species of earth, and that is supposed to be the best soil, in which the virtues of one portion of its constituent principles correct the faults or defects of the rest." To spread the sandy wash obtained by the road-side up-n sandy and gravelly soils; to put a dressing of vegetable matter upon the peat meadow or on a very black soil, would be "carrying coals to New Castle." It might not be entirely useless, but there is so much of the article already there that it might better be carried to places where it is less abundant. Is it certain that two loads of best manure from the stable would be much more serviceable on a light sandy soil than one load of manure and one of clay or tenacious mud? Can we say with confidence that pure animal manure will add more to the fertility of a vegetable soil than manure with an equal quantity of loam or sand? Would any other dressing be more valuable upon a clayey soil than one composed of half sand? May it not be true that much labor might be very profitably spent in carting soils from one portion of the farm to another, thus making more fertile ~~the~~ ^{the} ~~land~~ ^{land} ~~and~~ ^{and} ~~experience~~ ^{experience} give the expected answers to questions of this kind, we have, within convenient reach, abundant materials for enhancing the productiveness of our lands. A farmer, in the northern part of the county, informed me recently, that a thin coating of loam, upon wet meadow lands, has caused the growth of two tons of good English hay to the acre annually, for five or six successive years. No manure has ever been applied. Facts like this command us to give more attention than has been customary, to the mixture of soils.

The application of manures in a liquid state, so highly approved in Europe, should not remain long untried by us.

Observation satisfies me, that in soils not cold, unfermented manure, though less active than fermented in the early part of the season, will be found the most serviceable at the time when our crops need their greatest supply of nourishment. I have seen the two kinds tried repeatedly upon turnips sowed in August. In September, the plants upon the older and finer manure are far in advance of the others, but in November the tables are turned. The yield will average twenty-five per cent. more where the manure is applied in its green state. Corn, too, though more yellow upon this in June, will show as much yellow, I think more *above the husks*, in September.

Bone manure, last season, did pretty well. In all the operations I have aided to make with it the present year, it has been so mixed up with other

ingredients that it is impossible to judge of its efficiency. The corn where it was used, wore in the early part of the season a most sorrowful and forlorn aspect; the warm suns of July, however, enlivened its spirits and changed its complexion. Its present size would rebuke me were I to assert that it has not found somewhere a pretty good supply of nourishment. In the field of a friend, who left his corn to feed upon bones and meadow mud, or starve, its aspect a few weeks since indicated that the food was either difficult of mastication or hard to digest. Its growth was less vigorous and its appearance less healthy than that of the surrounding corn upon different diet. A rust, a bad rust, was upon all its leaves, while the neighboring corn on all sides was bright and healthy in its appearance. Probably you can find more economical means of enriching your soils than that of procuring bones.

Book farming. Do the words produce a sneer? Be that as it may; the thing, or what is often stigmatized as *that thing*, is not contemptible. For what is it? Not an attempt to comply with the advice and copy the example of every one who furnishes an article for an agricultural journal; not the adoption of every method of husbandry that is recommended in print; not a departure from all the usages of our fathers and neighbors; not a preference of the theories contained in books to the results of experience. No. I pity the stupidity of the man who thinks that if we use books, we must close our eyes against the light that is beam-~~ing~~ ^{ing} ~~from~~ ^{from} other sources; or that we must become mere theorists, and the victims of ruinous experiments. What I does a man lose his common sense, his prudence and his judgment, whenever he takes up an agricultural paper or opens a book upon husbandry? Cannot one make himself acquainted with the doings of others without losing his power to judge whether it would be well for him, in his circumstances, to copy their examples? Our brains are not so weak as this. The knowledge acquired from books does not make us all mad. But if it did, there would be more zest and true enjoyment in the learning mad-man's course, than in that of him who has learned out, and who thinks that books cannot make him wiser. I asked what book farming is? Common book farming is learning by means of books, new facts, opinions, results of experiments, modes of operation, and the using such parts of the information as can be turned to profitable account in our individual situations. If this be folly, we are content to be called fools. An agricultural paper will be worth to you every month, if not every week, more than its annual cost.

I have a few words for the farmers' wives. However skilful, industrious, and prudent your husbands may be, their success in money making depends as much upon you as upon them. Economy and skill on your part, in turning every thing to the best account, are essential to profitable husbandry. Perhaps there is scope for study, experiments, and improvement in your departments. All are not equally successful in the management

of the dairy. Poor pastures, poor cows, poor cellars, are the alleged reasons for the difference in results. These things undoubtedly are often the causes of failure to obtain butter in large quantities and of good quality. But may not the fault *sometimes* lie with the *dairy woman*? Is her business so simple as to be always well understood? You begin to suspect that I doubt whether some of you have perfectly mastered the art of butter-making. It may be an ungallant doubt; but listen to the particulars of one case in point and then judge whether I can help doubting. As stated to me, the facts are these. One of our farmers, the summer before the last, employed successively and for short terms each, three different dairy women. Here the cows, the pasture, the cellar, and all the dairy apparatus were the same; and how was the result? One obtained seventeen pounds of butter per week, the second twentythree, and the third twentyseven. Such facts should induce many of you to vary your processes and note results.

Philanthropy, looking forward, sighs at the consequences which must follow from changes that are taking place in the employments and habits of your daughters. Circumstances beyond your control have thrown the heedful spinning wheel and loom upon the pile of rubbish in the garret. Housework and the dairy do not furnish sufficient employment for all the females. Either mothers or daughters must resort to something else by which to contribute a share in the support of the family. It is too commonly the case that the daughters resort to some occupation that is not sufficiently active and invigorating. The needle is taking the bloom from many of their cheeks and vigor from their frames. The evil is augmented by that mode of dress, (I ought to use a harsher term,) which obstructs the natural and healthy development of the lungs and chest; also by imprudent prudence in avoiding exposure to the weather; and a too effeminate reliance upon the horse, for services which heaven intended should be rendered by their own limbs! The lamentable consequences will not be confined to them; children will inherit the feebleness of their mothers, and a sickly race will come after us.

Useful as the needle is, and beautiful as are its contributions to our show, I appeal to the mothers, to forbid its *excessive*, its *constant* use by the daughters. I entreat them as they value the well being of their children, to give the daughters daily and thorough training in the care and labor of the dairy and of all household affairs. It were well—well for them and for a future race, that they should revive the acquaintance which their mothers and grandmothers had with the milking-stool, the garden, and to some extent the field; for then, bloom would linger upon their cheeks; health would flow in fuller tides through all their veins; they would acquire vigor of body and soundness of mind, that will contribute to their usefulness and enjoyments when time shall bring them to the places which you now hold—shall make them the wives of farmers and mothers of the rising generation.

The command which Adam received, "to till the ground," was merciful in its design, and has ever been beneficent in its operations upon mankind. The husbandman's labors give healthful exercise to the body; and where he is attentive to the beauties, changes, laws, and mysteries of nature, his pursuit may furnish most profitable employment to the intellectual and moral powers,

Health finds as peaceful a home, and holds possession as securely, amid the tranquil nerves and the firm sinews that are covered by the farmer's sunburned skin, as is furnished for her by the men of any other occupation whatsoever. No other pursuit is attended by greater bodily comfort. But young men and boys are prone to imagine that some more cleanly and less active pursuit would be more agreeable and less exhausting than the cultivation of the soil. The browned face, the hardened hands, the aching back, the stiffened limbs, the muddied trowsers, and dirtied shirt, are unknown in the school room, at a merchant's counter and in the shops of many mechanics. Half the world avoid the dirt and hard labor which the farmer must encounter. It is not surprising that the young, observing this, should desire to quit the farm. Experience and observation have not yet taught them that every pursuit brings aches and various annoyances; or that dirt and hard work are not among the fatal foes to enjoyment. Perhaps a word from one who has experienced the sensations of both the student and the farmer, may not be worthless. The farmer's aches bring good digestion and quiet sleep. The night will repair the wastes of the day. But the excited nerves and throbbing temples of the student bring dyspepsia and exhausting restlessness. Morning often finds him languid; unrefreshed by his unquiet sleep. My oft repeated experience proves that the ordinary labors of the clergyman on the Sabbath are felt more on the following day, than is a tolerably vigorous use of the scythe, the pitch-fork, and the rake, for ten or twelve hours. Whenever called upon to labor seven days in the week, I have found myself least disposed to exertion on Monday morning. My advice to the young would be, never to quit the farm in hopes of finding an employment more conducive to their physical comfort.

Abundant food for the intellect and range for its exertion may be found in the sphere in which the farmer operates. Whether this pursuit has in ages past given sufficient employment to the minds of those who have tilled our soils, comes not within the range of my inquiry. Our farmers have not been the accurate and constant observers, the faithful recorders and logical reasoners, which the spirit of the present day is calling for. Husbandry in this region has been pursued in a less scientific and intelligent manner than its nature and importance demand. This is beginning to be known and felt; many of our farmers are waking up to the business of improvement, and give promise of favorable results. The work, however, is merely commenced. Many of the important principles of agriculture are yet but partially known, if known at all, among us; very imperfect, if any, records are here kept of the results of different processes, and of the cost and worth of different crops. Vagueness and inaccuracy characterize too much of our knowledge of our own pursuit. Could you, brother farmer, be induced to undertake to make the annual address before this Society, I fear that you would not be very certain about many matters which you now consider perfectly settled; your supposed knowledge, if not composed of more substantial stuff than mine, would mostly slip through the fingers, as soon as you attempted to grasp it and write it down. You might find that your observations have been less minute and accurate than you suppose; that your experiments have been conducted with

less care than you imagine; and that you are less well acquainted with your own business than you suspect. Such a lesson does no harm. I am tempted to wish that you might all learn it. You would then be made to know that we have scarcely commenced some of our appropriate studies—the study of the nature and composition of the various soils and various manures; the study of the habits and wants of the various grains, grasses, and roots; the study of the first principles of agricultural science, and of their application. Then you might perceive that our pursuits can furnish daily and abundant employment to every faculty of the mind, as well as to every limb and muscle of the body.

You might, if placed where I stand, suspect that one would find it serviceable to record whatever new knowledge he acquired, to keep accurate and full accounts of his expenditures, and his income. The difficulties which embarrass me at every step of progress in collecting matter for this address, induce me to advise every young farmer to keep a journal; to note down where and how he spends each day, to record his observations upon different modes of cultivation, the growth of crops, and everything connected with his pursuit. This journal might be so kept that at the close of the year it could be posted, and show the cost and value of each crop, and each variety of animals upon the farm. I know not in what other way one can learn with accuracy the comparative profits of his crops or stock. Such knowledge is surely desirable, and can be obtained. If procured in the way here recommended, the farmer's labors will become more intellectual and interesting than they now generally are. For the habit of recording at night the observations of the day, would keep the mind awake to the occurrences around it; would cause one to be accurate in his observations; inquisitive for the causes of what he witnessed, and a reasoner from the facts so carefully noted. Thus the mind being kept active and bright would acquire a deepening interest in a pursuit which is constantly presenting new views of nature's operations. If properly pursued and explained, I see not why the business of husbandry need be less attractive to the intelligent, active and enterprising boy, than is the business at the merchant's counter, the mechanic's bench, or on the merchantman's deck. But to render it such, more employment must be furnished for his mind than most of us had in the days of our boyhood. The boy is directed to learn in the school-room; but on the farm he must work. This is very well, though I cannot allow that it is enough. More pains than is usual should be taken to teach boys the best methods of doing their work, and the reasons for those methods; more care and experience bestowed in procuring for them the best of tools, particularly the scythe. I know not how a farmer can display greater inhumanity and improvidence, than by setting a boy to learn to mow with one of his worn out and cast off scythes; if, with the man's greater strength and many seasons' practice, the tool cannot be made to cut, what can be expected from it in the feeble and inexperienced hands of the beginner! But what I wish to present most distinctly here, is, the importance of disclosing to boys the reasons for nearly all the operations upon the farm. This method will give them a greater interest in their labors: will furnish occupation for their minds; will make them observers of the advantages and disadvantages of different modes of cultivation. It will lead them to study Agriculture in that period of life when the senses

the most active in noticing the various natural phenomena, and when the mind forms its most abiding habits.

Moral and religious character may be formed and nurtured as readily and successfully by one who is devoted to this most natural of all pursuits in any other of the many employments of man. One I believe will doubt that virtue and holiness are as often found in the farmer's home as beneath the roofs of any other class of our citizens. The plume of inspiration may be and is as reverently studied there as anywhere; and the husbandman must be constantly receiving salutary lessons from an "elder scripture," nature. In its moral tenets, this pursuit commends itself to all who cultivate virtue and piety at their proper worth.

But how does it speak to him who inquires for its culinary results? It answers in honest terms; its promises are less liberal than are made by most other pursuits, but its performance is more to be relied upon. It offers a comfortable support and it yields this more generally than almost any other occupation.

What is its repute in the world? How does it affect one's standing in the community? In what estimation are farmers held? Let us not be deceived by appearances. The striped frock and wide boots are not often introduced into the doors of the refined, the fashionable, and the rich. The unpolished husbandman is not the chosen companion of the refined merchant and professional man. And why thus? Not, I sincerely believe, because the better portion of those who move in that are called the first circles, regard the farmers less deserving of honor and esteem than themselves and their associates, but because there is a want of similarity and coalescence in the manners, bits, tastes and feelings of the two classes. Those who are robed in costly apparel may honor a laborer in his homely garb, and yet think, and justly think, that it would contribute to neither his joyment nor their own, to seat him at their elegant tables or receive him at their social parties. They know that this would be but cruel kindness; indecency; an attempt to mingle oil and water. The pursuit is respected as highly as any other. We, then, farmers of Essex, give contentment a permanent home in your hearts.

Destructive storms, withering drought, and killing frosts will sometimes disappoint our hopes. But it is wise to avoid the too common habit of over-estimating losses and speaking of them in a tone at borders upon complaint. The public journals often intimate that we are a complaining if not ungrateful brotherhood. I fear that our common, but thoughtless modes of speaking, will too nearly justify them in casting upon us the reproach. Let us, if ever we must, on that side which shows a con- fiding trust in the unsearchable wisdom and bound- less power of Him who has promised that "seed sown and harvest shall not fail."

"O fortunatos nimium, sua si bona norint
Agricolos."

has been echoed by every age since it fell from the lips of Maro's polished muse. Its truth may pass unquestioned. Though pleasure and happiness may be strewn as thickly upon the paths in which high- minded and faithful mechanics, merchants, manu- facturers, physicians, lawyers and divines wend their various ways, as over the husbandman's fields, it is yet true, that farmers would be a happy class, could they but appreciate in all its fulness, the

good they may enjoy.—And I close, Farmers of Essex, by appealing to you to be contented with your honorable pursuit, and to press forward with "unfaltering and unwearied steps," in the processes of acquiring Agricultural knowledge, of improving your farms, and increasing your productions; by appealing to you, also, and above all, to sow to the spirit, that you may pluck unfolding flowers, and gather immortal fruits in the fair gardens of the world above.

For the New England Farmer.

CROSS-BREEDING

AND BREEDING IN-AND-IN, IN THE VEGETABLE KINGDOM.

The terms cross breeding, and breeding in-and-in, are familiar to most of your agricultural readers, when applied to animals, but may not be so well understood when applied to vegetables, therefore a communication on this subject may be acceptable to some of your readers.

By the term cross breeding I would be understood as meaning that process by which the pistil, or female part of a flower becomes impregnated by the pollen from a flower of a different variety of the same species.

By the term breeding in-and-in, as meaning that process by which the pistil of a perfect flower becomes impregnated with the pollen from its own stamens, or those from another flower of the same variety, or in case the plants belong to the class Monœcia, by pollen from the male flowers of the same plant.

By the first process the object to be attained is to produce new varieties partaking of the nature of both the varieties from which the offspring is produced.

By the second process the object is to continue any well known, and valuable variety, by producing new plants from seeds, which shall retain all the valuable properties of the parent and so continue them, as with animals, for any length of time without degenerating by intermixture with inferior varieties.

Fully aware of the benefits which have resulted to the agricultural world, from the attention which has been paid by certain individuals, to the improvement of animals, both by cross breeding, and breeding in-and-in, I would inquire whether similar benefits might not accompany a like attention to the fructification of plants?

My object in calling the attention of horticulturists to this subject, is to inquire whether some process may not be discovered by which the flowers of our fruit bearing trees may be so impregnated, as to enable us to continue and multiply any known valuable variety, by raising young trees from seed so impregnated, at a cheaper rate, and with the prospect of greater durability, than we do at present by budding, grafting, or any other method now in general use.

Sir A. Knight has already enlightened horticulturists by his numerous experiments, made in what I term cross breeding, by which he has produced many new and useful varieties, both in annuals, biennials, and perennials, yet at the same time he sanctions the theory, that each plant produced from seed is a new generation, and as such has its limited time of duration according to the nature of the plant, when not only the plant itself but all propagated from it by budding or grafting will also die.

According to this theory the time will come

when all our present valuable varieties of fruit will become extinct. If this is correct is it not desirable that we should adopt some method to preserve them by reproducing them from seed? In what manner can this be effected but by breeding in-and-in?

By his theory of cross breeding he lays it down that the tree produced from seed when so managed, is a medium between the two varieties made use of in the fructification, in size, color, and flavor, but that the new plant in growth bears a strong resemblance to the mother, or plant which produced the seed.

We know many plants produce flowers, which from their peculiar shape, the parts of fecundation are so enveloped that it renders it very difficult for the pollen from any other plant to approach the pistil unless by artificial means. In such plants we rarely notice any variation—such are the flowers of the bean and pea, while others fully exposed, and that at the season when bees and other insects are numerous, as the *Bassica* tribe are constantly liable to sport, or produce new varieties.

Have we not reasons to believe that the pollen from different flowers act upon the same pistil, and in different degrees, each producing a corresponding effect upon the character of the future plant? And are not the pistils of perfect flowers, as the apple sometimes, so nearly impregnated with their own pollen as to produce plants from their seeds with but little variation from the mother plant? Upon what other principle are we to account for the great similarity that is found to exist in certain families of apples, viz: the Junettings, Seekno-furthers, Pippins, Russetts, and some others which might be named? In the first of these we have no less than four distinct varieties, "alike yet various," all possessing the general characteristics of the family which are singular—such peculiarity of growth of tree, time of ripening of the fruit, its size, shape, color, and flavor. The same observations will apply equally to the Seeknofurthers, of which we have three varieties very distinct, and a fourth which so nearly approaches as to leave little doubt as to its parentage. The Pippins also are becoming a numerous family.

I am convinced that if the principles of the fructification of plants were more generally understood by our agriculturists and horticulturists, and that emulation excited which exists among those engaged in the breeding of animals, that a corresponding improvement might be made, and attended with as fair a profit to the persons engaged, while for every improvement they would merit the lasting gratitude of their country.

I am, gentlemen,
Your obt'
N. GOODSSELL.

In the year 1497, in a fish pond in Suaba, a Carp of prodigious size was found, which had in its ear a ring of copper, with these words in Latin inscribed upon it:—"I am the first fish that was put into this pond, by the hands of Frederick the Second, Governor of the World, the fifth day of October, 1130." So that this Carp must have lived to the remarkable age of more than two hundred and eighty-seven years. We wonder, says an old writer, whether this memorable fish was doomed to end his days in a stew-pan!

ROBERT COLT'S FARM IN PITTSFIELD.

The answers of Robert Colt to the questions proposed.

Question 1. Of how much land does your farm consist, exclusive of wood land?

Ans. Three hundred acres.

2. What is the nature of your soil—does it consist of sand, gravel, clay, loam, or peat?

Ans. It consists (with the exception of 12 acres of peat, or what was a few years since a black ash swamp) of loam, with a hard pan subsoil, and a mixture of lime stone.

3. If a part, or all of the above kinds, what do you consider the best method of improving them?

Ans. By a rotation of crops, viz., first, oats on green sward; second, corn or root crops, with a dressing of manure; third, wheat, barley, or oats, (prefer wheat or barley) with a stocking six quarts (or 12 lbs. clover and 8 quarts of herds grass seed, and remain clover two years and then taken up. Always plough in the spring, and on sward use a colter. My reasons for this are these: sward lands that are ploughed in the fall, become compact during the winter, the finer parts washed between the furrow slice excluding the air, and preventing the surplus water from draining off, consequently the turf lies dormant, with but little benefit to the crop. On the other hand, plough in the spring, the soil is light, and receives the harrow kindly, and the furrow slice does not become so compact as to prevent the circulation of the air, and allows the excess of water to take its proper course, and the land, when the crop comes off, will be in a more forward state of decomposition than if ploughed the fall before. I am fully satisfied from experience, years since, that the ploughing of green sward or stubble in the autumn, is a loss on the following crop of at least 10 per cent.

4. How many acres do you till, and how many cart-loads of manure (meaning by cart-loads 30 bushels at least) do you put on an acre?

Ans. Fifty-five acres,—fifteen of which are hood crops; manured with 20 cart-loads of compost manure to the acre.

5. Is your manure applied in its long or green state, or in compost?

Ans. Given under the preceding question No. 4.

6. Do you spread and plough in your manures put upon fields to be planted with corn or potatoes, or put into the hills?

Ans. Is found under questions 13 and 14.

7. What is your method of ploughing and cultivating green sward?

Ans. Given under question 3d.

8. How many acres of upland do you mow, and what is the average quantity of hay upon an acre?

Ans. Sixty acres—average 2 tons per acre.

9. How many acres of grass land do you irrigate—at what season, and how long do you allow the water to flow your land, and what is the effect?

Ans. I have no lands so situated as to allow irrigation.

10. Do you manure the lands irrigated, or any other land you mow—how much to an acre—and what kind of manure do you put on?

Ans. I manure 20 acres a year with 10 loads of unfermented sheep manure per acre, drawn out upon a sled from the sheep folds before the snow is off, in March, and spread immediately after the ground is bare, and the next year the land thus manured is plastered with 2 bushels to the acre.

11. How many acres of low land not suitable for the plough do you mow,—and what is the quantity and quality of hay cut the present year?

Ans. I have 12 acres of red top with a mixture of clover and herds grass, that give me this year 2 1/2 tons per acre. This piece of land six years since, and at the time I purchased the farm, gave me 5 loads (about 3 tons) of coarse wild grass, most of which had to be carried out upon poles, as it was too wet and miry for a team to pass over it. A part was then hedged and cleared off, and that season cleared the remainder, and drained the whole thoroughly. The next spring, or five years ago last spring, I gave it a dressing of 10 loads of unfermented sheep manure per acre, and 2 years last spring I gave it a similar dressing of manure, and the last spring a part of it, and it has not given me less than two tons, and from that to three for the last five years, of a good quality of stock hay; and a team can now take a load of hay over any part of it without injury to the land.

12. What is your method of reclaiming low, bog, or peat lands, and what has been your success?

Ans. After draining it thoroughly, extract the stumps, alders, or what it may be wooded with, pair the bogs and burn them all together upon the ground, sow a crop of oats, and stock it with clover and herds grass or red top. The kind of seeding would depend entirely on the state of the land, whether it be wet or dry. The ashes being left upon the land and spread, would throw up a vigorous crop of oats, which will destroy all, or most of the wild grasses. Ashes have a fine effect as a top dressing on low lands, while lime, so far as I have made the experiment, is worthless.

13. How many acres of corn have you planted the present year—what was your mode of preparing the ground and the seed—the kind and quality of manure used to an acre—the manner of applying it, and the quantity of corn raised to an acre?

Ans. Seven acres of corn upon an oat stubble, ploughed from the 1st to the 10th of May, and spread on the furrow 20 loads of compost manure per acre, followed with a thorough harrowing and tightly ridged 3 feet 4 inches apart, with a double mould board plough, which covered the manure; planted the seed dry; the hills two feet apart on the ridge. A part of the seed was 12 rowed yellow, called the "Cady corn;" the remainder, the Manchester 8 rowed. It was run through with the cultivator and dressed with the hoe three times, on the 17th June, 6th and 20th of July, with a sowing of plaster at broad cast, of 2 bushels per acre after the first hoeing. On the 16th September cut up and stooked; and lusked on the lot three weeks after, and stalks secured. The product was 110 bushel baskets per acre. I also sowed two rows of the flat turnip after the last hoeing, and in October fed off by my sheep.

14. How many acres did you plant with potatoes the present year—what was your method of planting—your manner of cultivating—and what the average quantity raised on an acre—and what kind did you plant?

Ans. I planted 4 acres upon a clover sward; ploughed on the 20th May, with a dressing of 20 loads of manure per acre, most of it compost, spread and harrowed in upon the surface; furrowed lightly, (not to disturb the turf) 3 feet apart; potatoes dropped 20 inches apart upon the surface between the furrows and well earthed. On the 29th June dressed with the cultivator, and slightly earthed

with the hoe, and two bushels of plaster sowed at broad cast, per acre. On the second week of October I harvested them, and the average was 400 bushels per acre; 300 of which were the Mercer and pink eye for the table, and 1300 of the flesh colored, called the Burr, for feeding my stock.

15. What number of acres of other vegetables did you plant—what kind, and how many bushels of product had you to the acre, and to what use shall you apply them?

Ans. Four acres; 1 of sugar beet, that gave me 600 bushels; and 3 acres of ruta baga, which produced 800 bushels to the acre. This crop was planted on land from which a potato crop was taken the last year. It was ploughed twice, dressed with 20 loads of manure per acre; harrowed and ridged 28 inches apart; sowed with a drill harrow one row on a ridge. The crop was dressed out with a hoe twice, on the 10th and 25th July, and plastered at first hoeing, and was harvested on the third week of October. My beets are fed to my swine after steaming, and to my milch cows with cut corn fodder. My turnips are cut and fed to working oxen and young cattle with cut straw, and to my ewes at and before lambing, grated and mixed with cut hay. My principle is, to feed no grain or roots to cattle, sheep, or horses, without being mixed with a portion of cut straw or hay. Two bushels of grain or roots fed in this way, is worth 8 bushels to pass through the stomach alone, particularly if fed in large quantities at a time.

16. How many acres of winter or spring grain did you sow the present year—how was this ground prepared—what quantity of seed did you sow on an acre—if you have raised wheat, of what kinds—the nature of the soil—and was it sown with or without using lime?

Ans. I sowed 40 acres, namely, 20 acres of oats. This field last year was a stiff sward pasture; ploughed early and sowed to oats; stubble and clover ploughed in during the first week ending the 4th of May last, and harrowed thoroughly before sowing 2 1/2 bushels oats per acre, cross harrowed and stocked with 4 quarts of clover and 8 of herds grass per acre. This field gave me—judging from a portion threshed—60 bushels per acre. A light dressing of plaster was cast on the lot the last week in May. Ten acres of wheat and oats upon sward ploughed the 6th and 8th of May, harrowed lengthwise of the furrow; sowed with 1 1/2 bushel of oats, and half bushel of wheat per acre, harrowed well both ways after sowing. It gave me 50 bushels per acre. I sowed 10 acres of spring wheat from the 18th to 20th of April inclusive, on a loam soil, (from which was taken a crop of corn and roots the last year) ploughed twice, and harrowed, and sowed with 1 1/4 bushel of Tea wheat per acre, except two acres, 2 1/4 bushels per acre, all rolled in lime, after having lain in salt, and saltpetre and water 12 hours. Stocked this part of 10 acres with 6 quarts of clover and 6 quarts of herds grass to the acre; harrowed, and designed for mowing. On the 24th of August finished the harvesting of my wheat, and was satisfied that there was a difference of 15 per cent in favor of 1 1/4 seeding to the acre to that of 2 1/4 bushels per acre. The number of shecks cut from the field was 266; and judging from the yield of that already threshed, it will give 28 bushels to the acre. It is very essential that all lands designed for small grains should be well harrowed before sowing. Some experiments made this year in my oat crop by sowing upon the fur-

row were almost a failure. In my experiments last year with Tea, Italian, Silician, and Red Chaff Wheat, I came to the conclusion that for our soils, and to escape the fly and rust, the Tea wheat stood first. I think that all wheat ought to be put into the ground as soon as possible after the opening of the spring.

17. How many acres have you laid down to grass the present season—at what time in the year did you sow it—how much seed to the acre, and was it sown alone, or with a grain crop?

Ans. I have laid down to grass 30 acres this season; sowed the last of April and the first week in May, all with grain crops. On 10 acres of which, designed for mowing, I sowed 6 quarts of clover and 6 of herds grass per acre, and 20 acres with 4 quarts of clover and 8 of herds grass per acre for pasturage.

18. What are your means, and what your manner of collecting and making manure?

Ans. In the fall my yards, both cattle and sheep, are covered from 4 to 10 inches with muck hogs and manure taken from my ditches and low grounds, the amount of from 80 to 100 loads, and a sufficient quantity of leaves to bed my stock during the first of the winter. The last of March, all the green manure made by my sheep is hauled out as a top dressing upon my mowing grounds, and all that is made after this, together with the stable manure, on the last of April is heaped in the yards with the muck, and remains a few days until partially fermented, and then taken out for root crops. I collect at all seasons of the year muck, earth, leaves, and any vegetable substance that will absorb the urine, with my horse manure, and place it in my piggery; this is afterwards taken out and piled, and covered with earth or muck for my corn crops.

19. How many oxen, cows, young cattle, and sheep, do you keep through the year—what is the size of your barns, and have you a cellar under them—is your manure covered?

Ans. I have 6 oxen, 6 cows, 14 young cattle, 4 horses, and 900 sheep. Nine-tenths of my manure is under cover. The size of my barns is as follows—

No. 1. 108 feet by 36, with a shed at one end 46 by 16 feet, on the other end a shed 24 by 12 feet, with a barn attached 36 by 22 feet. These buildings are placed on a side hill, and have a basement story, and can be secured from cold by doors.

No. 2. 44 by 24 feet, with a shed at each end 18 by 36 feet. This barn has a cellar for roots under one of the bays, 16 by 12 feet.

No. 3. 30 by 40 feet, with sheds at each end, 24 by 30 feet.

20. Are your calves of the native, foreign or mixed breed?

Ans. My calves are cross of the Devonshire, young cattle Devon and Ayrshire.

21. What is your management of calves intended to be raised?

Ans. Take the calves from the cows and feed them with 3 quarts of new milk twice a day for 3 months, adding after they are 3 weeks old, a little rye and corn meal scalded, then weaned off upon dry provender and grass, roots, or hay, as the season may be.

22. How much butter did you make this year, and how much cheese, and what proportion new milk?

Ans. Owing to my having raised 14 calves, I

have made little or no cheese, and have made about 100 lbs. butter.

23. How many swine did you keep, what quantity of pork did you make, and of what breed were your swine?

Ans. I have 24 swine, 17 to winter, and 7 for pork, that will weigh 2000 lbs.; they are of the Berkshire, and most of them of the pure breed.

24. What do you feed them upon through the summer months, and on what do you fatten them?

Ans. They are fed during the summer months, on clover, mowed and given them in their styes—with shorts, water and the waste of the house. Commence fattening with equal portions of potatoes, apples, pumpkins, and from this to equal parts of sugar beet and potatoes and a portion of oat and wheat provender, and at last with corn meal, their food being cooked and fed to them warm.

25. How many cart loads of manure do you take from your hog styes in a year, and of what materials is it made?

Ans. I make 20 loads by collecting muck, leaves and earth with the coarser part of the horse litter.

26. What number of hands are employed on your farm, and what do you pay for labor?

Ans. I have one man and a boy through the year, two extra men 6 months each spring and summer in addition; in addition in haying, paid 30 days by the day. Wages vary from \$10 to \$12 in the winter, and from \$12 to \$16, spring and summer, per month, and \$1 per day in haying and harvesting.

27. What is the number of your apple trees, and are they of natural or grafted fruit?

Ans. I have 100 bearing trees; most of them have been grafted by myself within the last ten years, with choice selected fruit.

28. What number of fruit trees have you, exclusive of apple trees?

Ans. I have 40 pears and plums.

29. Have your trees been attacked by canker worms or borers, and what is your method of destroying them?

Ans. They have not.

30. In the cultivation of your farm, do you allow the use of ardent spirit?

Ans. Not in the least.

It would be proper here to state that in addition to my farm I hire for the purpose of pasturing my sheep, a mountain lot, for which I have paid \$90 for the year.

The above answers are true according to my best knowledge and belief. ROBERT COLT.

Pittsfield, 2d Dec. 1839.

Examination of Mr Colt's Farm.

The farm lies in a body, on a ridge or swell of land, of rather an uneven surface, with considerable many hills or prominences and dales; some of the latter are or were moist and unproductive; but a small quantity however, is now unproductive. The ridge extends north and south, and the farm is mostly on the east side of it, that is, there is but little of it on the west side. It is divided into convenient lots, and well fenced. There is considerable stone or rock (all limestone) on the middle section of it; on which also, are a small farm house, and two barns, 60 rods or more, apart, with good accommodations for keeping sheep, with convenient spring water for each. The principal house and barn is at the south end of the farm; the water is brought by acqueduct, and with several convenient outlets at the barn; both the house and

barn are new; the hogpen is under a wing of the latter, with a horse stable over it and a room for corn and grain. This barn is so arranged as to have sheep under the whole of it, except a central compartment (on the inner side) which forms a spacious cellar or vault, for vegetables. There is a little land not yet reclaimed, and some coarse grass; but the farm is well cultivated, and the general appearance, (though in an unfavorable season) is good. The cattle, sheep, &c. look well.

H. HUBBARD.

For the New England Farmer.

RAISING CALVES.

MR. ERROR.—Many have been the modes or methods, proposed and recommended for the raising of calves. Some recommend milk porridge, some water gruel, or meal and water boiled, some skimmed milk and Indian meal.

To make the best calves, with the least expense, I object to all these, more particularly to Indian meal, in any way, because I have always found that it causes the calves to scour, which is a great injury to them.

As every man is apt to think his own way the best, I will state mine, which is the best for me. It is to take the calf from the cow, when quite young, say a day or two old, learn it to drink new milk first, in such quantity as it will take, as there is not much danger of its taking too much when so young. When it drinks well, skim the milk that has stood from morning to night, or night to morning, and heat it, so as to give it to the calf blood warm, and two quarts at a time, twice a day; when the calf is a week or two old, let the milk stand longer before skimming and as he grows older, increase the quantity till it gets to four quarts at a time, twice a day. If the milk is scalded and then cooled to blood heat, it will be better. If the milk is given cooler than blood heat, it causes the calf to scour, which is very injurious.

I have raised nearly all my stock in this way, for many years, with very good success. My heifers and steers at three or four years old, will compare well with those that suck the cow till they are three or four months old. This method well practiced, not only makes good cattle, but for me is the cheapest—for generally the butter, by the time the calf, if fattened, would be fit for the butcher, will bring as much as the calf would, so that I get a good calf for the skimmed milk and a little work, and the work ought not to be thought much of, for farmers have nothing without work. One reason of my taking the calf off so young is, the cow forgets the calf sooner, and will be more quiet than when it is older; another is, it is in every respect better for the cow. A FARMER.

March 4, 1840.

At Raleigh, N. C., the season is so far advanced that the farmers are ploughing and the gardeners busy at work, while the peach and other fruit trees are much advanced in vegetation.

Butter is selling at Albany, at from 12 to 16 cents a pound. In New York and Philadelphia, from 18 to 25.

During the month of February, upwards of 23,000 barrels of flour were forwarded from Fred-eric to Baltimore.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, MARCH 25, 1840.

THE TENTH AGRICULTURAL MEETING

Was held at the Representatives' Chamber on Thursday evening last. Mr Brigham, of Westboro', presided. The subject allotted for the evening was Beet Sugar and Vegetables for Stock.

The Commissioner presented a valuable variety of corn from Messrs Ellis & Bosson, called the Pomroy corn. It is a short ear, eight-rowed, well filled out at the end, and a good bearer. We have known this corn a long time. With good cultivation on good land, it has yielded seven-ty-five bushels to the acre, and ripens seasonably.

He presented also some corn from the Messrs Hovey, which was a small eight-rowed ear, long and sound. It is cultivated in Worcester county, and greatly esteemed. The farmer who has planted it for several years, is anxious to allow but a single stalk in a hill; but this stalk produces four and five ears. We are promised more particulars in regard to this corn, which we shall give when received. It is greatly esteemed by those who cultivate it, and its appearance is much in its favor.

He exhibited, likewise, some potatoes, produced by Mr Pollard, of Maine, from the seed of the Chenango. They wore a large long potato, resembling in appearance the Cow-horn; and said by those who had cultivated them, to be uncommonly excellent. They were distributed among several farmers, who will undoubtedly give a good account of them.

He exhibited, also, a model bee hive, of a cheap construction, since it is made of a common flour barrel, and suspended to a tree or any other convenient position. It is the invention of Mr John Sholl, of New York city, apianian, No. 557 Houston street. We do not choose, whatever our private opinion may be, to pronounce it superior to any other; because there is seldom right or propriety in attempting to elevate one man by putting him upon another man's shoulders; besides that, no man likes to have his shoulders used for a stool; but we think it greatly to be commended for its cheapness; and the provision for extracting the surplus honey without robbing or killing the bees. It is thought, too, from the mode of entrance that it affords an efficient protection against the bee moth. This, however, remains to be proved by the only perfect test, experience. The hive is well deserving attention.

He stated, likewise, the merits of Weeks' Vermont hive, which is greatly to be approved, and a sample of which may be seen at Messrs Ellis & Bosson's. It is an excellent hive, and he will soon have a model for exhibition.

Mr William Clark then made some explanation of some remarks which had before fallen from him on the subject of Indian corn, in respect to which he thought he had been misunderstood. He did not wish to be understood that corn might be planted as closely as any one might choose; and the more thickly planted the more productive. There was of course a reasonable limit; but understanding it with proper qualifications, the more thickly planted, where the condition of the ground admitted of it, the more corn would be grown upon an acre. Nor would he be understood that the more thickly the corn was planted the less likely was the land to suffer from drought. In his opinion it was otherwise; as (as we understood him,) the more thickly the ground was covered with vegetation, the greater would be the abstraction of moisture from the earth.

Mr Teschemacher then exhibited a specimen of a most

fertile soil which had been brought from the island of Batavia, with plants for the Botanical Garden. This gave upon analysis 24-300 of vegetable and animal matter.

The subject of Beet Sugar then coming up, Mr Teschemacher after a few remarks, was followed by Mr D. L. Child, Mr Bosson, Mr A. W. Dodge and others. The reports of their remarks as well as of the preceding meeting on the subject of silk, are in preparation, but of necessity deferred to another occasion.

The meeting voted unanimously that the thanks of the meeting be given to the several publishers of newspapers in Boston, who have kindly and gratuitously inserted from week to week the notices of the agricultural meetings.

This meeting closed the series of meetings for the season. They have been throughout most respectably attended. They have drawn the attention of the public strongly to the great subject; they have been conducted throughout in a courteous and agreeable manner, without as we are aware, of the occurrence of a single unpleasant feeling or remark; they have elicited much information; and been attended with great interest and pleasure. We conclude as we began, "Speed the plough." H. C.

We have no room to extend our editorial, and insert a communication on the subject of the Worm in Locust trees. This with another on the cultivation of the Yellow Locust, (which will be given in our next,) should have accompanied the report of the committee of the Massachusetts Agricultural Society on Mulberry Trees and Live Hedges, published in the Farmer of the 11th. There are other communications belonging to this report which will be given in our next, and we shall hasten the publication of the other papers connected with the reports of farms, with all practicable dispatch. H. C.

OF THE WORM IN THE LOCUST TREE.

To Peter C. Brooks, Wm. Prescott, E. H. Derby, Josiah Quincy, jr., and Elias Plimney, Esqrs., Committee of the Massachusetts Society for Promoting Agriculture.

GENTLEMEN—In your List of Premiums under "Experiments, Discoveries and Inventions," is the following: "For an effectual and satisfactory mode of extirpating the Worm that attacks the Locust tree."

You will please indulge me in a few remarks relating to the locust tree, one of the most valuable and durable trees for fencing, posts, or ship's use; being convinced of its utility, and in consideration that the charters of our agricultural societies are based upon giving encouragement for the growth of timber trees, each being required to appropriate a portion of their funds to that special object. The Hampshire, Franklin and Hampden Agricultural Society very early took this subject into consideration, and have annually offered premiums to encourage the growth of the Yellow Locust, having other forest timber in abundance.

Not knowing, however, where to procure the seed, as secretary of the society, I wrote to various places in New England and the middle States with no success, until the editor of the N. E. Farmer advertised the wishes of this society; and from that time to this, there has been plenty of seed in market, of which I have availed myself, and transplanted from my nursery to a very poor soil, annually, some thousands of the locust trees from the seed, and began setting them at the distance of about two rods, but soon commenced setting them about six feet apart every way, that the branches might the sooner shade the soil and cause the grass to grow where scarcely any vegetable grew before. Another object for setting the trees so compactly was, to partially exclude the light from the body of

the tree and prevent the insect from attacking the tree when protected by shade.

Upon the same principle, the inhabitants on the borders of the Connecticut, on tide water, where there is considerable ship building, who are paying us, among others, one dollar per cubic foot for locust timber, to prevent the effects or injury of the borer or worm, are removing young locust trees and transplanting them into the midst of other forest trees, for the benefit of its umbrage, and to obtain more sound timber than could be had from the open fields and fence borders.

Between the years 1824 and 1830, I had sparsely set over several acres, with all the tops and branches, and found that many trees perished for want of sufficient root to support the tops; and was necessitated annually to replace them with other trees; but within the last few years, have set out roots with only a few inches of stump above the root, and have had vigorous shoots in return; and have now 1764 fine trees, more than three years old, standing compactly on about an acre and a half: although some have been set 14 or 15 years, yet standing so close, have not attained a great size: the largest may be 6 to 8 inches diameter and 20 feet high or more.

In illustration of the effects of the rays of light, direct or reflected, I would mention that a few years since two locust trees for shade, were set in front of the court house, in Northampton, at the distance of about 17 feet from the east front wall: both of these were subsequently attacked by the insect; not so much on the sunny side of the trees as the southerly and sides facing the court house; the brick walls of which are painted of a light straw color. The tree set at the S. E. corner was so much injured by the insect that it came over in about three years after setting, both of which were sound and uninjured at the time of setting out. One tree is now standing and about 12 years old, 8 inches diameter and about 30 feet high. It was supposed that the reflection of the sun from the walls of the court house, might have been congenial to the habit of the insect, and the occasion of the greatest deprecations, occurring not where the rays of the sun were most direct.

The condition of these trees confirmed the opinion that an umbrageous location for the locust tree was necessary, to avoid the evil complained of. One year, when the perforations of the tree were more numerous than usual, and appeared as if recently made, it was observed that there were many very slender green lively bugs passing in and out of the holes, and when approached, if they could not scamper away, took to the wing, but immediately returned to the tree: some of these bugs were nearly half an inch long: the holes were frequently scraped, pared smooth, and some of them grew over. On a more critical examination, small eggs were found deposited in crevices of the bark. The body of the tree having been thoroughly scraped, no additional injury has occurred since, nor have I heard of or seen a similar insect. A few of them were put into a vial for preservation, but small ants took possession and became their executioners.

Having procured a tract of about twelve acres of the most sterile soil, at a place in Northampton called Rocky Hill, to experiment upon with the locust tree, have taken great pains to eradicate and prevent the deprecation of the insect, and am pleased to find my plantation of locust on the interior secure, and even on the exterior so little injured. The trees now growing produce abundance of seed, and there is beneath the trees a plentiful crop of luxuriant grass. Within the last 4 or 5 years, I have set out many hundreds of trees, not counted among the 1764; and have more than 5000 seedlings of this year's growth, and hope eventually to have eight or ten acres of the most worthless soil covered with the locust tree; and by estimate, taking into consideration what has been done and taken from soils, think I may be encouraged with the

belief that every acre thus set with the locust, within 30 years from the time of setting the seedlings, (15 years on good land would do the same,) might have a growth of trees worth from one to three thousand dollars, and the trees of nine now growing, in less than 15 years more, may be worth, for ship timber, from four to five thousand dollars; whereas the land for the cultivation of any kind of grain, is not worth five dollars the acre: Nevertheless the present year, on less than half an acre of the same poor soil, have been grown 15,000 splendid large leaf Canton trees, worth at least 3750 dollars: this shows on what inferior soil this most valuable mulberry will flourish.

From the foregoing it may appear that the most effectual mode to extirpate the worm or insect from attacking the locust tree, is to exclude as much light and heat from the body of the tree as is consistent with its growth, by dense plantation, or by transplanting the trees into the midst of other forest trees.

All of which is humbly submitted by
DANIEL STEBBINS.

NORTHAMPTON, Sept., 1830.

P. S.—I am now about surrounding the borders of the locust with a row of horse chestnut, not only for ornament but to protect the borders from any supposed or real injury.

BRIGHTON MARKET.—MONDAY, March 23, 1840.

Reported for the New England Farmer
At Market 250 Beef Cattle, 35 pairs Working Oxen, 17 Cows and Calves, 230 Sheep and 950 Swine.
Prices.—Beef Cattle.—Sales were a little quicker without much advance from last week. We quote a few extra \$7 00 First quality, \$6 75 Second quality, \$6 25 a \$6 50. Third quality, \$5 50 a \$6 00.
Working Oxen.—A large number were sold. We notice the following: \$25 50, \$28 00, and \$31, \$28 50, \$30, \$100; two at \$21 1/2, \$15 and \$13.
Cows and Calves.—\$25, \$23, \$27, and \$42.
Sheep.—We did not learn the price.
Swine.—Lots to peddle at 4 3/4 and 5 for sows and 5 3/4 and 6 for barrows. Large selected barrows at 5 1-2 and 6. A lot to close, half barrows, 5 1-8 and a lot, two-thirds sows, at 4 1-8. At retail 6 and 7.

THERMOMETRICAL.

Reported for the New England Farmer.
Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending March 22.

TREES, SEEDS, &c.

WILLIAM PRICE & SON, Flushing, can supply as follows—Fruit and Ornamental Trees of all kinds, and the latter of very large size. Green House Plants; Endless Flower Roots; a most splendid assortment of Dahlias at \$2 to \$4 50 per dozen. Genuine Morus Mulcaulis, Alpine, Elata, Expansa, and other Mulberry Trees and Cuttings of the same at low rates and on a liberal credit for notes or good mortgages. Genuine Alpine, Broussa, Elata, Moretti, Rose of Lombardy, and White Italian Mulberry Seeds. Silk Worms! Eggs of the White and Yellow Peanant; Piedmont White and Yellow, Bologne large White, Manmout White and Yellow, Thrice shedding, (new,) Two crop White, and other choice kinds at \$3 to \$5 an ounce. 100 bushels fine Rolan Potatoes, of Flushing growth. The Mulberry Trees are in the most perfect condition, not a bud injured, and each one will produce more growth than a dozen of the miserable imported trash.
Priced Catalogues will be sent to every applicant and orders by mail will meet prompt attention.
March 25.

FOR SALE.

A short horned Durham Bull, bright red, four years old in April next, was raised by Gorham Parsons, Esq. at Brighton. Apply to MARTIN DAVIS, River Street, Dorchester.
March 25.

SILK WORM EGGS.

The Eggs of the celebrated *Silkworm*, now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The *Silk Worm* was introduced to France from China by Louis XVI in 1754, and has been traced by M. Beauvais to the superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously just received, by the subscriber, from the Chevalier Edouin who is the only agent for their sale in France.
Each sheet contains an ounce and is signed "Camille Beauvais." Price \$5.

Apply to JOSEPH BRECK & CO
March 25.

FOR SALE OR TO LET.

A wooden two story house, with six or nine of fettle land, situated in Medford, within half a mile of the village. Said house contains four rooms on the first floor and six chambers. The premises are plentifully supplied with a variety of choice fruit trees, in a thrifty and bearing condition.
A portion of the land is a superior location for a sheep yard. The above is a pleasant and desirable place for a country residence.
For terms inquire of JONATHAN BROOKS, near the premises, or WILLIAM BRIGHAM, No. 25 Court Street, Boston.
March 25.

GARDEN FOR SALE.

MOSES GREENLEAF, of Bolton, offers for sale about 10 acres of fine land, on which is a good house and barn, and a good assortment of fine fruit. He has raised on this ground Onions, at the rate of 750 bushels to the acre. Persons wishing to purchase would do well to call and view the premises, or inquire at the N. E. Farmer Office.
March 25.

TAVERN FOR SALE.

For sale, at public auction, on Thursday, April 6th, 1840, at 3 o'clock, P. M., the Tavern situated on Waltham Plain, known as the Green Tavern, formerly kept by Leonard Smith, now occupied by Nathan Nourse, together with the land adjoining, consisting of 25 acres of pasturing and Tillage. The premises are too well known to need a particular description. The house and land will be sold together, or the land in lots as may be desired. The sale will be positive and the terms liberal. For further particulars inquire of FRANCIS WINSHIP, Brighton.
March 25, 1840.

FRUIT TREES FOR SALE.

A good collection of Apple, Pear, Plum, Cherry and Peach Trees, for sale at the Pomological Garden, Salem, Mass. Salem, March 18, 1840. ROBERT MANNING.

BOX FOR EDGINGS.

JOSEPH BRECK & CO. have for sale 500 yards of Box for edgings, in prime order; price 3 1/2 cents per yard; every yard will make two when reset.

Giant and Early Wilmot Rhubarb.

Roots of extra large size at 25 cents per root, for sale by JOSEPH BRECK & CO.

Asparagus Roots.

Large transplanted Asparagus Roots, for sale by JOSEPH BRECK & CO.
Also—Strawberry Plants, of approved sorts.

PUBLIC AUCTION.

The subscriber having leased his Farm near this city, will offer for sale, on said farm, on Wednesday, the 23th day of March inst. all of his valuable stock of neat Cattle, being about forty head, mostly high bred animals, among which is one full blooded Durham Bull, four years old, from the stock of Col. Powell, of Philadelphia; ten or twelve Cows; three very fine yoke of working Oxen. The remainder young stock, very fine.
Sale positive and terms liberal. If the weather should be stormy, the sale to take place the first fair day.
Hartford, March 11, 1840. JOSEPH MORGAN.

BOX.

For sale at the Garden of SAMUEL DOWNER, in Dorchester a small lot of tall Box. Also, a large lot of short box, with fine roots and will make a neat border.
March 11.

TO FARMERS.

500 casks Lime, of good quality, for sale by the subscribers at their wharf Front Street.
We would remind consumers of this article that the casks are larger and have at least one fourth more in quantity than in former years. Price 112 cents per cask.
CARTER & WILLARD.

MISCELLANEOUS.

SELFISHNESS.

Within his house, in a great arm chair, before the fire, sat an old gray headed man, ripe for the grave. "T was winter; and the cold wind whistled among the leafless branches of the trees, and the snow and sleet rattled against the windows. The old man chuckled, for he was warm and comfortable, and the biting blast touched him not. He said, "I have enough—I am rich—so blow ye winds, and drift ye snows, I am safe." A servant entered and said, "Sir, a woman is at the door, trembling in the cold—and has no house to go to. She begs for a corner in your kitchen, to pass the night in." "Away; I've no room for thieving beggars—there is a tavern close by; tell her to go there." The servant delivered the heart-rending message, and returned; "She says she has no money, and begs you to give her enough to buy a meal and lodging." "Begone! Drive her off. What I've got's my own, and I'll keep it. I've none to squander on worthless mendicants."

The next morning the old man stepped out into his porch, and there, upon one of the benches, sat the poor beggar woman. His rage was kindled. "Did I not tell you I have nothing for you, impudence! Come, come, tramp; leave my house, I say; d'ye hear?" She heard him not! *She was dead!* The old man smote his breast, and entered his house. He never left it again—for he also died; and died miserably.

One of Cromwell's followers, who filled the important station of an Irish justice, at the period of 1661, having occasion to write the word *usage*, contrived to spell it without using a letter of the original word—thus "yowzitch." When some one remarked upon this specimen of his ignorance, he averred that "nobody could spell with pens made from Irish geese." It was the same fellow, probably, who first discovered that ingenious way of spelling "coffee"—viz. *kauphy*.

EARLY CEDO NULLI PEAS.

These very superior Early Peas, every way worthy of their name, are again recommended, and challenge my pen in America to beat them, being ready for the table on the 23th of May (if sown in March)—are, moreover, *dear* and *inexpensive* bearers. All who had them last season gave them the character of being not only the earliest, but best pea ever raised. The following short note near home will give an idea of their success; it is from Mr Vaughan, Long Island, dated 26th May, 1839. "On the 7th of March I planted your cedo Nulli Peas, and have them on my table today; had the early part of this month been as favorable as April, they would have been, I don't not, ten days sooner, as they were in bloom the 1st of May." Other references near this city, and in Dutchess county, can be given, if required. Price 25 cents per quart; may be planted the moment the ground can be worked.

Also, Early Warwick Peas—a fine sort—25 cents per quart; Early Race Horse (a new kind from England), 50 cents per quart; Knight's Dwarf Green Marrows, 50 cents; Dwarf Blue Imperial, 25 cents; and fine Dwarf Marrow-falls, 25 cents. Also, English Broad Windsor Beans, Sword Long Pod Beans, Early Mazarin Beans, 25 cents per quart. These should be planted in March, to succeed in our climate. Also, Early York Cabbage, Cauliflower, Broccoli, Purple Egg Plant, Tomato, Squash, Pepper, Early Scarlet Radish, &c. &c. suitable for hot beds. Also, Early Potatoes, several varieties. GEO. C. THORNBURN.

March 11, 1840.

CATALOGUE

OF

CHOICE IMPORTED PEAR AND PLUM TREES.

JOSEPH BRECK & CO. have received, by the Switzerland, a choice collection of Pear and Plum Trees, selected from the Nursery of the celebrated Chevalier Soulaige-Bodin, Jardin du Fromont, near Paris, and embrace some of the finest varieties now cultivated. Those who would like to make additions to their collections would do well to make an early application, as many of the varieties will soon be exhausted.

PELMS.

- No. 1. Reine Claude Violée.
- 2 " " dorée.
- 3 Royale de Tours.
- 4 St. Jean.
- 5 Monsieur Hatif
- 6 " " Tardif.
- 7 Reine Claude Vert.

- B 38 Beurre de Benumont.
- B 39 Beurre de Malines.
- B 40 Nouvelle Mahle.
- B 41 Poire Auger.
- B 42 Doyenne d'hiver nouveau.
- B 43 Beurre pater roster.
- B 44 Beurre Roman.
- B 45 Beurre d' jel.
- B 46 Beurre Bronze.
- B 47 Galessemme.

PEACH TREES ON PLUM STOCKS—ESPALIERS.

- B 48 Grosse Mignonne.
- B 49 Madeline.
- B 50 Teton de Venus.
- B 51 Bourdine.
- B 52 Galande.

Gentlemen ordering any of the above trees will please to give the number, or the number and letter of those wanted. There has not been a finer lot of trees ever offered to the public than those in the foregoing lists, nor in better condition. They will be sold from 75 cents to 1 dollar each, with the exception of some of the new varieties, which will be \$1.50.

JOSEPH BRECK & CO.

March 25.

Fruit and Vegetable Garden, and Mowing Land. Two Miles from the City. To be Leased.

The subscribers offer to let on a lease of two or more years, the land situated in Dorchester, (about two miles distant from the O'd South Church, Boston,) belonging to Z. Cook, Jr. There is a garden on the premises of about 2 acres, having a southern aspect; well filled with fruit trees of every kind. The land is rich and strong, and can be made to yield early and abundant crops, and from its vicinity to the Boston Market, offers the greatest inducement. The remainder of the upland is now laid down to grass, of which it yields abundantly, and there are several acres of salt marsh immediately adjoining. A large and convenient barn is also upon the ground.

The above will be let upon the most favorable terms, on application to
3w COOK & COFFIN.
No. 65 Commercial Wharf.

FOR SALE OR EXCHANGE.

A valuable farm in Harvard, County of Worcester, the well known Bromfield Place; an excellent dairy farm, well wooded, the house spacious, fitted for two distinct families. The situation among the best places to be found, especially for private or High School. Bordering a part of the farm is a beautiful sheet of water, containing two islands belonging to the estate. Inquire of the Subscriber at South Natick.
March 4, 1840. H. T. BLANCHARD.

FARM FOR SALE.

For sale, a superior farm of nearly fifty acres, between Boston and Lowell, 15 miles from the former place; on which is situated a convenient dwelling house, barn, and other buildings in good repair, and an orchard of choice fruit trees. For further particulars inquire of the subscribers, No. 52 North Market Street. JOSEPH BRECK & CO.

N. E. FARMER.

PREMIUM FARM REPORTS.

Statement of Joshua K. Lawton, of Great Barrington, whose farm obtained the second premium of the Massachusetts Agricultural Society.

Question 1. Of how much land does your farm consist, exclusive of wood land?

Ans. 185 acres, having added 12 acres of pasture the present year.

2. What is the nature of your soil—does it consist of sand, gravel, clay, loam, or peat?

About three quarters consists of a sandy loam and loam, and one quarter of clay loam; all resting or based on limestone; no peat or gravel.

3. If of a part, or all of the above kinds, what do you consider the best method of improving them?

To break up or plough the sward land in 4 or 5 years, first spreading about 20 cartloads (I speak in reference to my means of manuring the farm,) of long or compost manure per acre before ploughing, for a corn and potato crop, which should be taken the first year of tillage; a crop of spring grain should be taken the next year, without applying manure, except plaster, which is as good ploughed in, unless grass seed is sown, (that is, the land is laid down,) and then it had better be spread after the grain has come up; if a third crop is taken before seeding down to grass, it had better be winter grain, spreading before ploughing, 10 or 12 cartloads of long manure; but after, if the manure is fine, to the acre; and sow on plaster in the spring following, a bushel to the acre, on both winter and spring grain. Grass land should not be fed down close in the fall, especially on clay or clay loam land. I sow a bushel of plaster to the acre on all my grass land.

4. How many acres do you till, and how many cart-loads of manure (meaning by cart-loads 30 bushels at least) do you generally put on an acre?

54 acres this year, and put on when I manure, from 12 to 15 such loads to the acre.

5. Is your manure applied in its long or green state, or in compost?

Both in a green state and in compost.

6. Do you spread and plough in your manures put upon fields to be planted with corn or potatoes, or put it into the hills?

I always spread and plough in manure for corn and potatoes, and sometimes in addition, put a little fine manure in hills of corn.

7. What is your method of ploughing and cultivating green sward?

I plough it in the spring and after the ground is settled and thoroughly dry, plough again from 4 to 5 inches deep, laying the furrows at an angle of from 30 to 40 degrees, thinking it better than to lay them flat, and harrow the first time in the direction of the furrow, and after, a little obliquely, till the ground is mellow—always using the double-jointed harrow, because it covers the turf with the soil, sinks into a hollow, in fine, by conforming its shape

to that of the ground, and does its work evenly and alike.

8. How many acres of upland do you mow, and what is the average quantity of hay upon an acre?

45 acres, yielding on an average 1 3/4 ton to the acre.

9. How many acres of grass land do you irrigate—at what season, and how long do you allow the water to flow your land, and what is the effect?

I do not irrigate any.

10. Do you manure the lands irrigated, or any other land you mow—how much to the acre—and what kind of manure do you put on?

I stack hay on the poorest part, in the hay season, and fodder it out in the winter, when I also on other poor parts, put hay or straw in pens and fodder it out; and in the spring, put a little compost on that which is moist.

11. How many acres of low land not suitable for the plough do you mow,—and what is the quantity and quality of hay cut the present year?

5 or 6 acres: the produce is red-top and fox-tail, and in quantity from 1 1/2 to 2 tons the acre.

12. What is your method of reclaiming low, bog, or peat lands, and what has been your success?

By draining and under-draining, which made that productive that before produced nothing.

13. How many acres of corn have you planted the present season—what was your mode of preparing the ground and the seed—the kind and quantity of manure used to an acre—the manner of applying it, and the quantity of corn raised to an acre?

About 14 acres; which was green sward. I ploughed and harrowed as before described, spreading the manure before ploughing, about 15 cartloads to the acre, on 4 acres, and none on the remaining 10 acres, it having lain down 7 or 8 years. I planted the seed dry. The product was 36 bushels to the acre.

14. How many acres did you plant with potatoes the present year—what was your method of planting—your manner of cultivating—and what the average quantity raised on an acre—and what kind did you plant?

About 4 1/4 acres of green sward; ploughed and harrowed as aforesaid; being first spread over with green manure and compost, about 15 cartloads to the acre. I furrowed it both ways, 3 feet apart one way and 2 1/2 feet the other, and planted one or two whole potatoes in the angles, and ploughed and hoed them twice; raised about 300 bushels to the acre, principally the round pink-eyes, some ladies' bakers, Mercer, &c.

15. What number of acres of other vegetables did you plant—what kind, and how many bushels of produce had you to the acre, and to what use shall you apply them?

About one acre of ruta bagea—produce 800 bushels to the acre; and shall feed them chiefly to cattle and sheep.

16. How many acres of winter or spring grain did you sow the present year—how was the ground prepared—what quantity of seed did you sow on an acre—if you have raised wheat, of what

kind—the nature of the soil—and was it sown with or without using lime?

About 32 acres; 18 acres with spring grain, and on stubble ground, of a sandy loam and clay loam, ploughed one inch deeper than I plough sward-land, harrowed once previous to sowing; sowed 2 bushels of Italian wheat rolled in lime to the acre, and 3 bushels oats to the acre; no manure was put upon it. [I sowed the wheat from the 18th to the 20th of April, and had a good crop; not a head of that sown the 20th had an insect in it, but a few heads of that sown the 18th, had.] The remaining 14 acres was stubble and fallow ground, and was ploughed and harrowed the same as were the 18 acres, and was sown with winter rye, in a dry state and 5 pecks to the acre.

17. How many acres have you laid down to grass the present year—at what time in the year did you sow it—how much seed to the acre, and was it sown alone, or with a grain crop?

51 1/2 acres—37 1/2 in the spring, with 7 quarts timothy and 3 quarts clover seed to the acre; 14 acres of which with a grain crop, and the residue, 23 1/2 alone; and 14 acres this fall with a grain crop, with 7 qts. timothy seed to the acre.

18. What are your means, and what your manner of collecting and making manure?

My means are the droppings of my cattle, &c., hay, straw, wash of street, soil and turf carted from the highway. I put them in barn-yards and hog-pens.

19. How many oxen, cows, young cattle, horses, and sheep, do you keep through the year—what is the size of your barn or barns, and have you a cellar under them—is your manure covered?

From 2 to 4 yoke of oxen, according as my business requires; 6 cows, 10 young cattle, 4 horses, and 400 sheep. (I hired pasturage this year to the amount of \$55.) Have two barns; one is 30 by 60 feet, with a cow-house as high as the barn, 24 by 51 ft.; the other, erected this year, is 35 by 45 feet, with a cellar under it, and a straw-house attached to it, 20 by 30 feet. The large spaces under the buildings are accessible to cattle, sheep and swine, and will cover a large proportion of the manure. Water is brought in aqueducts to the barns as also to the piggery.

20. Are your cows of the native, foreign or mixed breed?

They are mostly native.

21. What is your management of calves intended to be raised?

I have generally taken them from the cow at 4 days old, and fed them 2 weeks on new milk, and after on skimmed milk till they are 10 or 12 weeks old, and then put them wholly to pasture.

22. How much butter did you make this year, and how much cheese, and what proportion new milk?

About 500 lbs. butter, and 1200 lbs. cheese—of new milk.

23. How many swine did you keep, what quantity of pork did you make, and of what breed were your hogs?

I have kept 50 swine this year; 23 are of the

gross, crossed with a French breed, and '27 (the offspring of the former), are crossed with the Berkshire breed. I made over 7 1-2 thousand pounds of pork last year, and shall make about that quantity this year.

24. What do you feed them upon through the summer months, and on what do you fatten them?

Keep them through the summer months in a clover pasture altogether; and fatten them on boiled potatoes and ruta бага and Indian meal mixed together and fermented—until the last stage of fattening, when give nothing but scalded Indian meal.

25. How many cart loads of manure do you take from your bog styes in a year, and of what materials is it made?

70 cartloads, and is made of straw, soil, &c., taken from the highway.

26. What number of hands are employed on your farm, and what do you pay for labor?

Three hands through the year and one additional hand in haying and harvesting; and pay \$14 per month.

27. What is the number of your apple trees, and are they of natural or grafted fruits?

100—mostly of natural fruit.

28. What number of fruit trees have you, exclusive of apple trees?

About 20.

29. Have your trees been attacked by canker worms or borers, and what is your method of destroying them?

They have not been.

30. In the cultivation of your farm, do you allow the use of ardent spirit?

I do not.

The above answers by me made are true according to my best knowledge and belief.

JOSHUA K. LAWTON.

Statement of Inspection of Mr Lawton's Farm, Amount of Produce, &c., by H. Hubbard.

Mr Lawton read to me from his farm book as follows, viz:

Estimate wheat raised this year,	337 1-3 bush.
—Rye,	191 "
Oats,	365 "
Ruta Бага,	885 "
Potatoes,	1200 "
Hay,	78 tons.

His farm is all but contiguous: the 12 acres pasture purchased this season, is a few rods off on the N. W., and it is divided by the road running across the S. E. corner, where the dwelling house and barns, &c. are, with the meadow, some pasture and wood-land on the E. and S. There is a ridge back (west) of the house, of moderate height and acclivity, where the orchard is, but rising higher and growing steeper as you go north to his northern boundary. The main part of the farm lies on the top and west side of this ridge, falling or sloping gradually to the west, and rising gradually to the north, to about the middle of the farm, where the highest part of the ridge is depressed or spread out westerly into a wide and nearly level plain, dipping a little towards the south: here the farm too widens or extends to the west, and has buildings erected for keeping sheep, and hay is stacked in the field: it is very pleasant, and well cultivated, and the soil is warm and rich to the summit; not a barren or unutilizable spot on the whole. The farm is well fenced and divided into lots of convenient size; the house is in good repair, as are the other buildings,

barns, carriage house, corn house, and hog-pen, which last contains a collar on a level with and adjoining the area, where are the boiler and two vats on either side of it to receive the food, from which it is shoveled to the troughs in the pen lining the area. Water is carried from the aqueduct into the boiler by a movable spout. The water for the barns, &c. is taken from a spring in the door-yard. The sheep, swine, &c. looked well. Mr L. has a very commendable zeal and ambition to be a good farmer. Mr Colman, the Agricultural Surveyor, who has viewed this and Mr Colt's farm, may give a clearer description of the premises.

H. HUBBARD.

Examination of the Farm of Increase Sumner Wheeler, of Framingham, which received the Society's third premium.

The Committee, by their agent, having proceeded to examine the farm of Increase Sumner Wheeler, of Framingham, county of Middlesex, carried on by Persian H. Vose, find as follows:

That the said farm consists of two hundred and fifteen acres, exclusive of wood-land; there being thirty acres of wood-land on the outskirts of the farm. About seventy acres of mowing and tillage, and five acres of very ordinary meadow land. The land is generally susceptible of good production in grain or grass, but mostly and more particularly of the latter. Fifteen acres of light soil. The soil is deep, and the pan retentive, composed of gravel and clay.

Our Mode of Improvement.

A liberal supply of manure, as well as rotation in crops, we consider indispensably necessary towards the good management of a farm. It has been our usual practice to keep up the land from three to four years. Much time has been spent and pains taken for several years past in making compost manure, using one load of green manure with one or two of meadow mud or loam. The application of the meadow mud with manure to the light and high soil; that of loam to that portion of our soil approaching meadow land. We have purchased some bone manure this fall, which has been mixed with meadow-mud, and which we intend in the spring to apply, by harrowing, to the inverted sod of some portion of the fifteen acre lot above mentioned, and plant with corn. Three acres of land at the remote corner of the farm have been enriched by ploughing in a green crop of rye, and one of buckwheat, which we intend planting the next spring with potatoes.

How many acres tilled the present season?

Eighteen acres.

How many cartloads of manure, (meaning by cartloads thirty bushels,) do you generally put on an acre?

Of compost manure about forty loads to the acre, equal to ten cords.

Is your manure applied in its long or green state or in compost?

Both. Our practice has been to spread the long manure, and plough it in with a light furrow. The compost is applied to the surface with the cultivator and by harrowing.

Do you spread or plough in?

Both. We prefer spreading, and then mixing it well with the soil.

What is your method of ploughing and cultivating green sward?

We spread our long manure in the early part of

May, upon the green sward, and cover it over with a shallow furrow, taking care the next time we plough not to disturb the soil.

How many acres do you mow?

Fifty acres of upland.

What is your average production of hay?

One and a half to two tons; on some land, two and a half tons to the acre.

Do you irrigate or allow water to flow your land? No.

How many acres of low land unfit for the plough, do you mow?

Two or three acres, or next to none.

What is the quantity and quality of your hay cut the present season?

Mostly English hay, and about one hundred tons.

Do you reclaim low bog and peat lands, and how?

By draining and using the meadow plough, then applying compost manure and seeding down to grass. The result appears promising.

How many acres of corn planted this season?

Six and a half acres, averaging fifty bushels to the acre, which has been wholly planted this season by Wm. Buckminster, Esq.'s Corn Planter—about four or five kernels in the hill; distance of the rows three and a half feet by two, running east and west. If the land was ploughed in the fall, we spread on forty loads of compost manure to the acre; if not, the green manure is spread on the green sward, and ploughed with a shallow furrow, and compost manure harrowed in on the surface, amounting in all to about forty loads to the acre.

We planted this season two and a half acres with potatoes, and raised eight hundred bushels.

Our method of planting potatoes, which we consider *ceteris paribus* by far the cheapest and most productive, is this. We take a piece of green sward, plough it with a *side-hill* plough, fill the furrow with manure, and then drop the seed and cover it by another furrow, then plough two more furrows and plant again in the same manner. We dig the potatoes so planted with the *side-hill* plough, which combines two advantages—that of cheapness and of mixing the manure with the soil. The other method is the usual practice, sometimes manuring in the bill, and sometimes spreading, three and a half feet by two. The blue English potato is the kind generally planted.

We should have added under the head of cultivating corn, that we make frequent use of the cultivator, running it through the rows of corn three or four times during the season.

What other vegetables did you plant, and to what use shall you apply them?

Ruta Бага. We raised from two acres sown with Mr Willis' seed-sower, about one thousand bushels, which we are now feeding to four cows and one yoke of oxen that we are fattening, and five calves which we are raising. We give them in winter to our milch cows, which we think increases the quantity and improves the quality of their milk, as well as betters their condition.

Of winter grain we raised none: of spring grain, sixty bushels of oats; fiftyseven of barley, and twentytwo of wheat. We made use of the Bedford oats, the Black Sea wheat, and two-rowed barley. The barley and wheat were sowed on land which was planted with corn last season, and oats on land planted with potatoes—the former seeded down, the latter to be again manured and planted this next season with corn. We sow two and a

half bushels of oats to the acre, two of barley, and one and a half of wheat.

Have you used lime?

None, it not being easily had.

How many acres laid down to grass this year?

Eleven acres. Four acres seeded in the spring. Seven acres of grass land, approaching the meadow and, turned over in September, then rolled, and twenty-two loads of compost manure applied to the acre, thoroughly harrowed and seeded and again rolled. It now looks very promising. We tried a year ago this fall, three acres of the same kind of land in the same way, and cut this season two and a half tons per acre. We sown one and a half to two pecks of herds grass seed, one bushel of red-top seed to the acre. In the spring we sowed twelve pounds of clover seed to the acre on the three acres seeded in the fall, and intend sowing twelve pounds per acre upon the seven acres. We do sow with the grain crop.

What are your means and what your manner of collecting and making manure?

Loam where it can be had, meadow mud from the ditches, and refuse vegetable matter. Having a cellar under the barn, we tie up our cattle—in the fall of the year we east in loam directly under their stalls and spread it. We keep our fat cattle in the cellar, and every morning throw under them a few shovels full of loam.

What is the number of your cattle?

Three yoke of oxen, two horses, twenty-six cows, (twenty-one only of which we have milked,) one bull, and five calves, which we are raising from our best cows. Also, one hundred and forty Merino and Saxony sheep.

What is the size of your barns?

One barn 84 feet by 36, and 21 feet deep bay; cellar under the whole—a part for manure and one end for vegetables. The other barn 50 feet by 33, standing lower, and of necessity without a cellar, which is used for our sheep in winter.

The breed of our cattle is native cows of well related native breed, principally. The bull, a part of English breed.

A part of our calves run with their mother—a part fed with skim-milk and meal.

How much butter made this year?

Twenty-four hundred and fifty-five pounds. (Most of our cows calved in the early part of winter.)

How much cheese and how much of it new milk?

Four hundred and seventy-eight pounds of cheese—fifty-five of new milk.

How many swine?

Eleven fat hogs and eleven stores.

Of what breed are they?

A crossing of the Mackay and Colombia county, New York.

We feed them in summer on boiled potatoes and skim-milk, and fatten them on potatoes, pumpkins, apples boiled and mixed with meal.

How many cartloads of manure do you take from your sty in a year, and of what materials is it made? One hundred cartloads, made of loam, meadow-mud and vegetable matter.

What number of hands do you employ, and how much do you pay for your labor?

Mr Vose's labor with one man through the season, at \$18 per month; 35 days labor in haying—a part of the labor done in haying with a horse rake.

The number of your apple trees?

About one hundred.

Are they natural or grafted?

The greater proportion natural. Have no other fruit trees.

The canker-worms and borers have not as yet appeared.

Ardent spirits have not been used on the farm for the last fourteen years.

We have sold ten hundred and seventy-five lbs. of pork, and have eleven hogs now to kill, which will probably average from 375 to 400 lb. each.—\$40 11 have been taken for pigs.

The amount of produce sold from the farm for the last seven years, has averaged two thousand dollars per year. The largest amount being twenty-four hundred and forty-four dollars. Only one thousand and fifty dollars worth of hay sold during the seven years.

[The following statement of Dr Stebbins, with the one in our last paper, should have been published in connexion with the Report of the Committee "on Trees and Live Hedges," given in the Farmer of the 11th ult.]

OF THE YELLOW LOCUST.

To Peter C. Brooks, Wm. Prescott, E. H. Derby, Josiah Quincy, jr., and Elias Phinney, Esqrs., Committee of the Massachusetts Society for Promoting Agriculture.

GENTLEMEN—Under the article of "Trees and Live Hedges" in your list of premiums, is mentioned the yellow locust tree, growing on not less than one acre nor fewer than 1000 trees per acre, raised from the seed, and not less than three years old, and in the most flourishing condition on the first day of September, 1839.

I have a grove or plantation of yellow locust trees, not before offered for premium to the Massachusetts Agricultural Society. The trees are of different ages and size; the first were planted out about twelve years since, from the seed, to which additions have been annually made, to supply the places of those which had perished for want of sufficient roots to support the tops; to avoid which, have more recently adopted the plan of heading them down to 3 or 4 inches above the root at the time of transplanting from the nursery, and with manifest advantage to the growth.

The trees are set at about an equal distance of six feet each way, requiring 1210 to an acre. The soil is very sterile, dry and gravelly. The growth has been slow, but if the trees had been planted on rich soil, they might have been of sufficient size to commence using very soon; but growing on so poor soil, will require from 12 to 15 years more to attain the most profitable size for use.

The object of setting the trees so close was, that they might the sooner shade the surface and promote the growth of grass. This object has been already realised to my entire satisfaction; where before nothing better than a few stunted weeds and running briars grew, nor did these "ill weeds grow apace."

The estimated value of the yellow locust is stated in another paper accompanying this; in addition to which it may be remarked, that from the sowing of the seed, the increase of value is estimated, by those who have for years cultivated the tree, at not less than twelve and a half cents for the product of each seed, *annually and perpetually*.

All of which is respectfully submitted by

DANIEL STEBBINS.

We hereby certify, that at the request of Dr Daniel Stebbins, we have counted his yellow locust

trees on Rocky Hill, in Northampton, being over three years old, and found the number to be seventeen hundred and fifty-four, and in a flourishing condition on the first day of September, 1839, growing on about one and a half acre of land and averaging more than one thousand to the acre; planted on a dry gravelly knoll, of very poor soil, yet there is a luxuriant crop of grass under the trees, while the land contiguous, of the same quality, produces only a few stunted weeds and running vines or briars. We estimated the average height of the trees at nine feet, and the average girth at half a foot, yet many are much larger and higher.

WILLIAM W. COOK.

(Northampton, 1839.)

For the N. E. Farmer.

ZOOLOGY IMPORTANT TO FARMERS.

A righteous man regardeth the life of his beast.
SOLOMONS.

This language, though uttered many centuries ago, and by one to whom wisdom was granted in compliance with his request, inasmuch that he has been reputed as possessing it in a superior degree through all intervening ages, is nevertheless by many of our enlightened day, considered as highly figurative, or else, as so far partaking of the mistaken ideas of those old-fashioned times, as to deserve being held in remembrance only as relics of antiquated notions. Hence we see men of every tribe and nation—every sect and party—of all ranks and in all situations—setting aside its injunctions and treating the animals which Providence has created for their convenience, enjoyment, and as the pioneers of wealth, as though they had actually been placed at their disposal as subjects on which they were to exercise all the rigors of spite and vengeance which their "little brief authority" can command. How strange must the infatuation be, which prompts or tolerates such conduct.

The beasts of the field were evidently created for the benefit of man, and in forms and for purposes adapted to his convenience. "The ox was formed for labor, and much increase is by his strength." The horse, adorned with beauty, is endowed with qualities for speed. And so the chain is filled up with links varying as the variations of his wants require. In return for the benefits which man receives from the beasts at his disposal, he has obligations towards them, which if he fail to perform, he is held reprehensible by the moral, and should be by civil law, while at the same time he is suffering pecuniary losses from his negligence towards them, inasmuch as the animal subjects itself to vicissitudes which it does not meet with in a wild and unshuffled state, by becoming his servant. Among these changes may be noticed the liabilities to disease which we believe in most instances among the brute creation, arise in consequence of an exchange from a wild to a domesticated state. As long as an animal ranges the fields or forests in native freedom, it is the judge of its own necessities and provider of its own wants. It eats such things as are congenial to its nature, drinks, lies down and rises up when it pleases;—but when brought under the jurisdiction of "the lord of this lower world," it must obey the injunction of eating "such things as are set before" it—"and learn therewith to be content";—while in drinks it is often brought under principles of "total

abstinence," yet sometimes allowed to drink to excess, and this at times when abstinence might be salutary. Fatigue in the animal is often rewarded with the whip, and as its strength decays, the excitements to go forward in its compulsory path are increased. Who can wonder, under such circumstances, that many animals are subject to sickness, and that many, very many, do not "live out half their days." Now, can man be a guiltless being when inflicting cruelties on his beasts, or when placing food before them which is calculated to create disease and pain in them? Justice, mercy, indeed every noble virtue which can warm the breast of philanthropy forbid it. And we, in charity to our fellow-men, believe that they would never be guilty of such outrages upon them, were they not ignorant of their nature, habits, &c.

Hence we infer the utility, if not the necessity, of those interested, making that science which has special reference to them, a part of education.—And first their anatomy. Whoever investigates this science will learn that like ourselves they are "fearfully and wonderfully made," and are admirably adapted to the circumstances in which our convenience may require them. Although they possess a general formation and habits of much hardness, yet there are delicate springs in their structure which, if roughly touched, will throw the whole machinery out of order. Thus in certain seasons, a moderate rap on the horns of an ox, will induce a disease, for which, comparatively, no one can apply an efficient remedy. And it is so through all their varieties, and in all the circumstances through which they are continually passing: they are liable to injuries at all times and in a variety of ways, which a knowledge of their structure and habits might teach us to prevent. The constitutional habits of the animals which come within the range of man's care, must necessarily be various as the different varieties. The fine sheep of Saxony will not bear the same management as the South-Down, or the "old-fashioned" sheep of our own country. Of course they will not succeed with such management. The difference may arise, to some extent, from change of climate, which may be remedied in a proper way; but there is a habitual and constitutional difference beyond this, which must be closely observed and its peculiarities regarded, by doing which, not only their health may be secured, but their pacific qualities developed and realised.

Loudon says, that "of all mammalia, man, in a demoralized state is most injurious. The remedy is furnished by law,—preventive, good education, civil and kind treatment." The remarks which apply to man, so far as preventives are concerned, are four-fold applicable to his beasts, inasmuch as the latter never swerve from the habits which education has enforced, and always reciprocate the civil and kind treatment which they receive from their boasting lord and master. The importance of early kindness to domestic animals is fully developed by the growth and the kindness of disposition which, thus early encouraged, characterises them in after years. So an ox which is accustomed to the yoke, even while yet a calf, is broken into his employment with less labor, and makes a firmer and more valuable ox than one whose disposition is unchecked, and whose corporeal form is allowed unrestrained growth for two or three years. He possesses more strength of bone and sinew. These remarks apply also to the horse, and indeed they extend in their proper application to all domestic animals. The cow which has always been kindly

treated, is a gentler, better cow, and of course rewards her owner more liberally. So with the sheep, and even the swinish multitude. The domestic animals do not confine their obligations to kind masters by mere labors of gentleness and servitude; they carry expressions of gratitude in their countenances for all the goodness manifested towards them, and look up to him as their benefactor and friend. In health, they meet our caresses with joy, and in sickness, with looks demanding our compassion, they demand our aid. How great is our obligation to make them happy, so far as happiness can be theirs, and how guilty if we neglect and abuse them!

But the domestic animals are not all, which motives of policy require should invite the study of the farmer. There are others which, mayhap, partake more of the nature of man, that demand his attention, and which, if left unnoticed and alone, will enter largely into the blighting of his hopes and destruction of those things for which he has labored. The sly, insinuating fox, the wolf, with many others, not excluding those of lesser character, such as squirrels, rats, mice, moles, which build railways with more than human speed through his meadows,—weasels, that infest his poultry-yard, &c. &c.,—all well enough in their places, but exceedingly apt to get out of their orbit. The invasions of these are to be remedied, and how? By making that acquaintance with their instincts which will subserve the end; not by a long and tedious course of observations,—though observations should be as constant as the circumstances which invite to them—but by making their history a subject of investigation, as we do arithmetic and every other, to whom circumstances have afforded more favorable opportunities to become proficient in these matters than we can expect, with our diversity of cares to possess.

W. B.
Mont Osceola, March 10, 1840.

For the New England Farmer.

BEAN PODS POISONOUS TO SWINE.

MR BRECK.—Some years ago, I had thrown into my hog pen, where there were six shoats, some Saba, commonly called Civy, bean pods. When I came from my work at noon, I found them all sick, vomiting and in very great distress. Not knowing then that the bean pods had been given to them, I went to dosing them with such things as I supposed might be good, but, in spite of all my efforts, in about one hour after my first discovery of their being ailing, five of them were dead. I opened and examined one of them, and found that all of a liquid kind was thrown up, and the potatoes with which they were fed in the morning, together with whey, were in a hard lump, and the bean pods mixed in with them.

Some suppose that it is the spur on the end of that kind of bean pod which does the mischief. I am of a different opinion, because those spurs, when green, are too soft to have any bad effect. I believe them to be poisonous: my hogs were evidently poisoned. Every man, who keeps hogs, and raises civy beans, ought to know that it is dangerous to give these pods to hogs, and that it may be more generally known, is the reason of this communication.

LEVETT PETERS.

Westborough, March 3, 1840.

From the Farmer's Cabinet.

MANURE, AND THE BIL EFFECTS OF DIRT IN STABLES.

The following judicious remarks on the preservation of the urine of animals, have been extracted from Hayward's Agriculture, and may be accepted as able and useful to the readers of the Cabinet.

"The superior effect of putting the manure on the land as it is produced, as stated by Sir H. Davy to be the case with Mr Coke, may be accounted for as arising from the urine absorbed by the matter which, if left in the usual way, spread in an open yard, would have been wasted and lost."

To show the fertilizing effects of urine, Sir H. Sinclair says, "every sort of urine contains the essential elements of vegetables in a state of solution. The urine of a horse, being so much lighter, would be more valuable than its dung, if both must be conveyed to any distance. The urine of six cows or horses, will enrich a quantity of earth sufficient to top-dress one acre of grass land; and as it would require four pounds worth of dung to perform the same operation, the urine of a cow or horse is worth about twelve shillings (£3) per annum, allowing eight shillings per acre as the expense of preparing the compost. The advantages of irrigating grass lands with cow urine, almost exceeds belief. Mr Hanley, of Glasgow, who keeps a large dairy in that town, by using cow urine, cuts some small fields of grass six times; and the average of each cutting is fifteen inches in length."

In a note to the above, the author observes, that "while recommending the careful and effectual draining of stables, for the preservation of the urine, as the most valuable part of animal manure, I will also state a circumstance which cannot be thought unworthy of notice to agriculturists, which occurred to me, to show how necessary this is also to the health of animals.

"I took possession of some stables, with the horses that had been some time kept in them, and, to my misfortune, in a very short time I found that horses kept in those stables had been subject to the dreadful disease called the mad staggers for several years. Some horses had died, and the horses then there, and which had been for some time kept in the stables, were in wretched condition. Two fine fresh horses which were put into them, were within a few months seized with the mad staggers, and one of them literally killed himself by knocking his head about against the manger and stall; the other was saved by copious bleeding and removed into a fresh stable, but was so reduced as to be lessened in value one-half. My neighbors advised the pulling down the stables, considering the disease infectious; but having, on going into the stables early in the morning, been almost suffocated and blinded by obnoxious gas, I examined the floor and drains, when I found the former to consist of large burr stones, laid on a stiff clay; and the floor sunk so low below the drain, as not to admit of the draining away of the urine. This struck me to be a sufficient cause to affect the brain of any animal confined in it, the same as it had the horses. I therefore had the floor taken up, relaid, and properly drained; and the walls and ceiling, manger, cribs, &c. washed with quick lime; and from that time for ten years, I never had a diseased horse."

The mad staggers is undoubtedly a violent inflammation of the brain of the horse, produced, in all

probability, by inhaling noxious, acrid gases, such as are the product of foul stables; for we never see cases of this disease among horses who breathe a pure, uncontaminated atmosphere. Horses which are kept in confined stables in cities, where the manure and urine are deposited in cellars underneath them, are most subject to this disease. The remedy, or rather the mode of preventing the disease, is so obvious, that every person who has charge of so valuable an animal as the horse, should be apprised of the importance of keeping a clean stable, so as to insure a pure atmosphere, that the lungs or brain may not suffer injury by inhaling ammonia gas or spirit of hartshorn, which tends to produce irritation and inflammation of the fine, tender membranes, which line the nasal processes and the lungs of all animals.

The disease called hollow horn in cattle, is inflammation of the interior of the head and horns, which communicate with the nasal processes, and very probably proceeds from the same cause which produces mad staggers and glanders in horses: to wit, foul acrid gases, inhaled in sufficient quantities, and for a time sufficient to irritate the very delicate membranous structure of the interior of the head, so as to excite inflammation, and finally suppuration, mortification and death. This is rendered the more probable, as horses and cows when stabled are generally enveloped in one common atmosphere, and the disease does not often show itself till the season is considerably advanced, when the foul malaria has had a long time to operate on the tender parts to which it is constantly applied while breathing. Milk cows are generally more closely confined than bulls or young cattle, and it is believed they are much the most frequent subjects of the disease. It is hoped this subject will claim the careful examination of all intelligent farmers, and it is desired that their observations may be recorded and published, whether they go to sustain the above theory or to destroy it. Of one thing we are all certain, that to breathe pure, uncontaminated air is more conducive to health, than to inhale that which is foul and irritating to the lungs. An occasional smell of a hartshorn bottle may not be disagreeable or unwholesome, if it is not too concentrated; but to be enveloped in an atmosphere of it for half our time, during the winter season, which is the case with a very large proportion of our horses and cattle, cannot be expected to promote the healthy action of the system, but on the contrary to produce disease and premature death.

AGRICOLA.

From the same.

A LETTER FROM PETER JONES ABOUT BOYS.

MR CABINET.—A neighbor farmer who reads the Cabinet with a great deal of pleasure, and speaks highly of its merits, hopes your correspondents will continue to favor the public with a continuation of their favors. He says he is growing old and stiff, and is not able practically to carry out the many valuable suggestions contained in your monthly sheet. He has several boys, as he terms them, though they are all grown to man's estate; yet he insists on calling them boys, and he says he is apprehensive they will continue to be boys all their days, yet he hopes they will be benefited by your paper. The fact is, Mr Cabinet, these boys were not reared right, although they are pretty steady,

moral young fellows, but they were permitted when young to fall into desultory, idle habits, working or letting it alone, as best suited their inclinations; the consequence is, that having now become men in age and size, they are boys still, and boys likely to be, unless your Cabinet eloquence should arouse them out of their present state of apathy. They know well enough what is right, but they hate to do it; they will come as well pretty well for a short time, and then relapse suddenly into their old idle, lazy habits, and let things take care of themselves. Now this is what I suppose doctors call a constitutional or chronic complaint that takes time to cure. These are the sort of chaps that are constantly trying to get something for nothing; to achieve great ends with little means; or as a friend of mine observed, to bore an auger hole with a gimblet; which you know is not an easy matter, and requires a full grown man of very considerable abilities to accomplish it, with any kind of decency, so that it is hardly worth while for a common lazy scab of a fellow to undertake so difficult an operation. Besides there has so many embarked in this mode of getting along through life of late, that the competition is so great as to produce great discouragement in the operators of latter time.

Agricultural produce has of late in consequence of a concurrence of circumstances, united with too much legislation, and that of a vicious quality, become much reduced in price, so that it behoves farmers to look sharply about them and see if they cannot make some improvements in their domestic arrangements that will counterpoise the low price of the products of their farms. One of the first movements in this reformation, perhaps, ought to be that of more economy, particularly in that valuable commodity called time, for "time is money," as poor Richard said, about one hundred years ago; it having stood the test of a century, and it is true still, showing in a remarkable manner the truth of the saying, that "truth is truth to the end of the world."

If people were taxed by the State to the amount of but one-tenth part of the time that is idled away or mis-spent, it would be deemed such an act of tyranny and oppression, that it would soon produce a revolution in the commonwealth; but voluntary taxes are cheerfully paid, whilst those that are imposed on us without our consent are grudgingly discharged.

Those who employ laborers to do work which ought to be performed by their own children, not only give away their money, but are doing a permanent injury to their own offspring; for every boy that is intended to be educated for a farmer, should be put through a regular course of practical instruction in every branch of business belonging to agricultural life adapted to his age and strength. There should be no selection of tit-bits for a favorite boy, if his best and permanent interests are truly regarded. There should be no entrance through the cabin windows, as sailors say; if a boy is intended for a seaman, a farmer, or for any other occupation, begin with him at the beginning, and put him through every part of the process thoroughly; if you spare, you spoil him. Many fine children are ruined for life by the indulgence of foolish fathers or silly mothers, in the endeavor to protect them from what they consider the hardships incident to a life of industry, and yet they are willing to ascribe the result to any other cause than the true one.

Instruct a boy thoroughly and practically in any useful branch of business—implant in his mind a

strong sense of religious obligation—instill into him the indispensable importance of industry and economy, and of the necessity of preserving himself free from every moral taint, and you may turn him out into the world without a cent in his pocket or a second shirt to his back, and he will succeed; he will establish a character and a name for himself; he will become a man of business in the true sense of the term; he will rise to eminence in his calling, what ever it may be; whilst those who appeared to have the start of him in the outset of life, being educated in indulgence and ease, with a prospect of ample means and influential friends to set them afloat, will lag behind and finally be lost sight of in the distance.

It is the poor boys of the present generation who are to be the men of business, the rich men of the next; and the rich boys of the present stock, if they don't mind their P's and Q's, will be their servants and hirelings. So argues a thinking old man of my neighborhood. PETER JONES.

Bucks Co., March 1st. 1840.

PROFESSIONAL LIFE.

The ambition of adopting professional life of all kinds, at the present day, is the source of countless instances of misery. Every profession in England is overstocked; not merely the prizes are beyond the general reach, but the merest subsistence becomes difficult. The "three black graces, law, physic and divinity," are weary of their innumerable worshippers, and yearly sentence crowds of them to perish of the aching sense of failure. A few glittering successes allure the multitude; chancellors, bishops, and regiments figure before the public eye; and every aspirant from the cottage, and the more foolish parents of every aspirant, set down the bauble as gained when they have once plunged their unlucky offspring into the sea of troubles, which men call the world. But thousands have died of broken hearts in these pursuits, thousands who would have been happy behind the plough, or opulent behind the counter; thousands, in the desperate struggles of thankless professions, look upon the simplicity of a life of manual labor with perpetual envy; and thousands, by a worse fate still, are driven to necessities which degrade the principles of honor with them, accustom them to humiliating modes of obtaining subsistence, and make up, by administering to the vices of society the livelihood which was refused to their legitimate exertion.—*Buckwood.*

Canker Worms.—Mr David Buffum, of Middletown, R. I., states that having an orchard of upwards of one hundred apple trees that had been badly eaten by the canker worms for a number of years, he, in the fall of 1838, had one-half of it guarded with the leaden roof and trough, invented by Jonathan Dennis, jr., of Portsmouth, R. I., and he is satisfied that if timely care and attention be paid to keep the troughs well supplied with oil at the time when the grubs ascend the trees, it will prove a thorough remedy. He states that he was so well pleased with the result of the trial, that he had the other half of his orchard furnished with the leads in the fall of 1839. The part that was supplied the first produced about seventy-five bushels of apples, whereas the other part produced scarcely any, having been eaten very much by the worms, while the part secured by the troughs was scarcely eaten at all.—*Erchange pap.*

For the Farmer's Cabinet.

BIRDS.

The great and the good protect, and the wicked and the vile destroy.

The season for the singing of birds having arrived, let us all unite in their preservation and protection. Let every parent discourse to his children on the advantages derived from the feathered songsters in the economy of nature. Tell them of the millions of insects destroyed by a single pair of little birds, during the season of rearing their infant family; and the millions of millions of pernicious insects which would be the progeny of those thus destroyed if they were suffered to survive for a single year. Inform them of the quantities of grain and grass, and fruit which perish annually by the depredations of the insect tribe, and that the birds are the only antagonists which we can avail ourselves of for protection from such insidious invaders of our rights. Remove the smaller birds which keep the insect tribes in check, and the earth would soon become one great desert, uninhabitable by either man or beast, for the food designed by Providence for sustenance, would be wholly swallowed up or destroyed by the myriads of insects which would speedily cover its surface. Beasts of prey and other invaders of larger growth, skill, and science can subdue or annihilate, but insects set all the boasted knowledge of mankind at defiance, and we have no protection for them but that which is furnished by our little friends the birds.

Now where is the boy, who knowing that his very existence depends on the industry and vigilance of birds, will be wicked enough to kill, and destroy, and persecute, and break down the habitations of his friends and protectors. Is there one to be found in this Christian country, who would do this, if proper care was taken to instruct, and enlighten him on this very interesting and important subject? No, not one. Therefore let parents and teachers be alive to this subject, give the rising generation suitable instruction, enlighten them, convince them of the wickedness, the inhumanity, the impolicy of destroying their best friends, and the great mischief will soon be stayed, and the birds will once more sing in peace and safety.

REB: CA.

INSECTS.—Some kinds of vegetables, as soon as they appear above ground, are very liable to be cut off by insects. The best preventive is to roll the ground immediately after sowing. This should always be done, unless the ground is too wet. The insects are thus deprived of shelter behind the lumps of earth—are more exposed to winds, storms, and extremes of heat and cold. Small chickens, turkeys, and ducks, the mothers of which are confined in coops, will destroy many insects in a garden. A mixture of dry wood-ashes, lime, and gypsum put into the hills or drills, and covered with a little soil before dropping the seed, afford protection to the roots from these insects that prey on these plants. Infusion of waste tobacco, lime-ashes, soot, cow-dung, elder, and some other leaves will, when moderately sprinkled over the beds, often drive off insects. Grubs may be destroyed by searching for them; and these insects that adhere to the leaves, may be destroyed with the leaves. Slugs are said to be enticed by slices of turnips on the beds, and early in the morning may be killed.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, APRIL 1, 1840.

POULTRY MANAGEMENT.

We give the following letter to our readers with great pleasure. The author is the distinguished temperance agent, who has sown the seeds of virtue and sobriety broadcast over Massachusetts, of which the harvest is already abundant. God bless him!—We understand that he stated in one of his lectures, that he taught his children to consider him as the handsomest man in the world. Don't let him insist upon our signing that creed without some qualification; because we think we have in the course of a pretty extensive acquaintance, seen one or two men quite as handsome. But then if "handsome is as handsome does," we must admit that he does a great many things very handsomely, and a great many very handsome things. Witness this essay upon poultry management. Though he has a great deal to say about eggs, he very properly says nothing about egg noggs or mulled wine. These are ungracious abuses of these excellent gifts, against which he eloquently protests. H. C.

To the Editor of the New England Farmer:

DEAR SIR—At your request I furnish for your paper a few remarks on the subject of chickens.

1. Never allow more than twelve hens to one rooster: a smaller number, say eight, would perhaps be better.
2. Never allow the roosters to go together: they are very jealous, and always pugnaciously interfering with each other's rights. The strongest lead away the hens: the consequence is, the eggs are fewer and do not hatch well. Hence the universal complaint that a larger number of hens are not as profitable, in proportion, as a smaller number.
3. Chickens require a good deal of water to soften their food, and gravel to grind it. They also require animal food. In winter they often cannot get water, nor gravel, nor insects or worms. They are well fed, it may be, with grain, yet do not lay. Supply their natural wants. Give them water, gravel and animal food, such as fat meat, liver, or indeed any kind of fresh meat. Keep them warm, not permitting them to become chilled, and they will lay as well in the winter as during any other season.
4. Do not permit your hens to set at different times, or rather only a few at a time. This causes broods of different ages, and the younger are usually injured or deprived of a fair quota of food by the older. When your hens manifest a disposition to set, let them remain on chalk eggs until as many as you intend to set are ready. Then place fifteen eggs under each hen. Select your eggs by holding them up to the light. Those which have bluish, watery specks in them had best be rejected. They do not hatch as well, nor are their chicks as healthy as the eggs that have no blemish.
5. When the young are hatching do not interrupt the hen. When hatched, feed them with Indian meal, with a large proportion of pounded egg shells. Hens that set "out," as it is called, generally have healthy chickens. I often have examined their nests, and seldom found any remains of the shells in them. The little ones eat them up. I have found that egg shells greatly advance their growth and health.
6. If all the little chickens could be taken from the hen and kept in a room warmed by a stove, I am satisfied from experiments, that they would do much better than to be with the hen.
7. Never allow the young chickens to get wet, nor to

become cold. See that they are supplied with ground worms (fishing worms.) They will repay you for this trouble.

8. Three times a year, at least, grease the head, throat, and under the wings of your chickens. A very small proportion of precipitate added to the lard is *à* service. You will never have your hens troubled with lice if you follow this rule and keep the hen-house clean.

9. Never allow your chickens to be without food. I have often been asked what is the best food to make hens lay? I have made several and repeated experiments to decide this question. The result is, give your hens and rooster, (who by the way requires as much, nay more attention than the hens,) water, gravel, and animal food, and they will lay as well on one kind of food as on another. Potatoes, corn, wheat, rye, oats, buckwheat, barley, and any thing that they will eat, will do. Boiled food is cheapest and best for hens, especially if kept up all the year, as they should be. I have followed the above rules ever since I owned chickens. We have always had more eggs than was required for use; and our chickens have never had any epidemic among them. With the exception of moulting season, that is when they shed their feathers, with judicious management, hens will lay for 260 days in the year.

10. Hens lay well and do well for four years. How much longer they would continue fruitful I know not.

11. There is a great difference in hens. Some breeds lay every day, until they empty the ovary. Others twice in three days. Others only every other day. The creole breed are the best layers I have seen, except a breed at Judge Burr's, in New Jersey, called Booby chickens. They lay every day. Eggs large; chickens strong, large and of quick growth. Hens set well.

12. Never frighten nor chase your chickens, unless they get into your garden. In that case I have found that the crack of a whip more effectually deterred them than any thing else, from venturing into forbidden ground. I do not know why it is, but they seem more afraid of the smack of the whip than any one would suppose who has never tried it.

If these remarks are not deemed sufficient, any other in addition will be cheerfully made when required, by

Yours, respectfully,

THOMAS P. HUNT,

WYOMING, Penn.

The Drunkard's Friend.

MAGNIFICENT INDEED!

The following product of pork, as the annual return of one farmer, though not all on one farm, is probably unrivalled in New England or Old England. These were all fattened the last year and sold as stated. Total weight, 44,303 lbs. Our respected friend at Lexington is now distanced; for which we frankly say we are not sorry, because we know he will not be sorry; and for the simple reason that he will rejoice in any new stimulus or incentive to agricultural improvement. When we published his account, we supposed he had reached the top of the tree; and we knew a good many snarling fellows who were trying to look at him, (though the eyes of such folks seldom leave the ground,) and crying out 'sour grapes.' What will they say now! Here is a Rhode Island farmer who has planted his feet upon *his* shoulders, and stands a full length above him. All we can do is to pray the Supreme Court of the United States, when they come to decide the disputed boundary line between the two States, by all means to take this good man and his farms into Massachusetts. We want him. We must have him,—though what is to become of our little sister, if we take him away, we do not very well see. But then why should we desire to rob Rhoda of her jewels? It would not be just. Let us wear brighter if we can.

We subjoin the following letter, and express our regret that it was a month in travelling from Pembroke to Boston, at least we infer so from the date, since it was not received until the 26th ult. The corn referred to has not yet reached us. Certainly if we cannot have a railroad between this and Pembroke, we may at least rail at the present road. H. C.

PEMBROKE, 26th of 2d mo., 1840.

RESPECTED FRIEND—I herewith send thee a few ears of flesh-colored corn, a variety which I have cultivated with good success for several years, and which has been esteemed as ten days or two weeks earlier than the common white corn; but as all corn tends to ripen a little later each year, farmers have found it necessary to change their seed in order to secure its perfection before our early fall frosts, and more especially for three or four years past, for which reason I have mostly discontinued cultivating this kind for two years past, although it ripened well the last season, and is remarkable for earing long and full and filling over the end of the cob, as thou wilt observe. The specimen here presented is remarkable for nothing but its abundant increase, being the entire production of one kernel of corn only, and is the more remarkable as it is well known that single blades of corn standing remote from any others, (as was the case in this instance,) are seldom as productive of full sound ears as those standing in fields. The history of this instance is, that a neighbor of mine, Capt. Joseph Cotes, found a single blade of corn growing in his garden among his other vegetables, and observing it to be vigorous and strong, cultivated it to its perfection: it had eleven beads for ears, on all of which there were sound kernels: he has counted the whole, and states them to be 2134 kernels, and I believe there is no doubt of the fact of this statement, although I did not see the corn when growing;

and being at his house a few evenings since, he produced them, and I solicited him to give them to me for the purpose of sending them to thee for exhibition, as a very large increase for one year's growth from one kernel. I have also inclosed an imperfect ear of the wild corn thou saw growing in my yard last fall. It was planted too late to come to perfection, and was killed by frost before it was full. Its cob and short husks may be a curiosity to those who have never seen a sample of this kind of corn.

With respect, I am thy friend, &c.
SAMUEL BROWN.
REV. HENRY COLMAN, *Agricultural Surveyor.*

BRIGHTON MARKET.—MONDAY, March 30, 1840.
Reported for the New England Farmer.
At Market 515 Beef Cattle, 25 pairs Working Oxen, 15 Cows and Calves, 140 Sheep and 1850 Swine.
Prices.—Beef Cattle.—The prices obtained last week for a like quality were not generally obtained. A very few extra brought \$7 00. First quality, \$6 50 a \$6 75. Second quality, \$6 00 a \$6 25. Third quality, \$5 50 a \$6 00.
Working Oxen.—We notice a few sales. \$80, \$90, \$92, and \$110.
Cows and Calves.—\$23, \$27, \$35, \$38 and \$42.
Sheep.—Sales not made public.
Sows.—Lot to peddle at 4 1-2, 4 3-4 and 5 for sows and 5 1-2, 5 3-4 and 6 for barrows. Large selected barrows, in lots of 25 50, 5 1-4. At retail 5 and 7 according to size and quality.
About 50 Beef Cattle and 60 Swine unsold.

THERMOMETRICAL.

TO LET.
A large Garden, Green House and Hot House, situated in Cambridge, about one mile north of the University, and within three miles of Faneuil Hall Market. Said Garden contains about four acres of excellent land, and the houses are spacious and convenient, and well stocked with young grape vines. The above described property will be let upon moderate terms. For further information application can be made to the subscriber in Cambridge.
Cambridge, April 1. 31* OZIAS MORSE.

ASSIGNEE'S SALE OF FARMS.
Will be sold at Public Auction, without reserve, on Saturday, the 4th day of April, 1840, at 4 o'clock, P. M. on the premises.

All the right, title, and interest of the Assignees of John Parkinson, in the Wait farm, so called, on Back street, in Roxbury, containing about one hundred and sixty six acres, consisting of tillage, woodland and pasture, with a Dwelling House and convenient out buildings. One large barn, 50 by 44 feet, a cellar under the same and another barn of a smaller size. The farm is about five miles from the State House in Boston, and is well watered with streams and good springs. The farm has been occupied and improved by Mr. John Parkinson, for the last thirteen years as a milk farm. Also, all the right, title and interest of said assignees, in and to one undivided half part a moiety of another farm adjoining the said Wait farm. The whole consisting of about forty seven acres, with a dwelling house thereon. The farms may be viewed on any day from 11 to 4, P. M. on application on the premises. Conditions at sale. By order of the Assignees.
Roxbury, April 1, 1840.

TAVERN FOR SALE.
For sale, at public auction, on Thursday, April 9th, 1840, at 3 o'clock, P. M., the Tavern situated on Waltham Plain, known as the Green Tavern, formerly kept by Leonard Smith, now occupied by Nathan Nourse, together with the land adjoining, consisting of 25 acres of pasturing and Tillage. The premises are to be well known to need a particular description. The house and land will be sold together, or the land in lots as may be desired. The sale will be positive and the terms liberal. For further particulars inquire of Francis Winship, Brighton.
March 23, 1840.

MISCELLANEOUS.

THE HORSE.

On Eastern plains—his native land—
Free, uncontrolled, he paws the sand;
His mane streams in the desert wind,
As faints the caravan behind;
And neighing at their hapless fate,
Flings out his heels in scornful hate;
Nor stops, till at some fountain's side
He cools his bright and reeking hide;
And thinks how better off he is,
Thus matchless in his liberty!

On meadows green a fettered slave,
He still is proud, sagacious, brave;
By him the earth is tilled—the land
Yields generous crops at his command.
He leads the advance guard of war;
Brings tidings from all lands afar;
Serves faithfully till life is past,
And drags us to the tomb at last!

THE CULTIVATION AND USE OF TEA.

Tea has become an article of such general use, that few persons in our country are ignorant of its color and taste. But many years have not passed, since it was unknown in Europe or America, and some people were so unacquainted with its use, that they at first boiled the tea leaves as they would boil greens. Even now, when so much of this article is consumed in the country, many persons are ignorant of its culture and the manner of its preparation.

The tree, or rather shrub, from the leaves of which the beverage called Tea is made, is a native of China and Japan, in which countries alone it is cultivated for use. It is an evergreen, somewhat resembling the myrtle in appearance, and grows to a height varying between three and six feet. It is capable of enduring great variations of climate, being cultivated alike in the neighborhood of Canton, where the heat is at times almost insupportable to the natives; and around the walls of Peking, where the winter is, not unfrequently, as severe as in the north of Europe.

The best sorts, however, are the production of a more temperate climate; the finest teas are said to be grown in the province of Nanking, occupying nearly the middle station between the two extremes of heat and cold. The greatest portion of what is brought to the Canton market, and sold to the European merchants, is the produce of the hills, but populous and industrious, province of Fokien, situated on the seacoast to the north east of Canton. It appears to thrive best in valleys, or on the sloping banks of hills, exposed to the southern sun, and especially on the banks of rivers or rivulets.

The first European writer who mentions tea is Giovanni Botero, an eminent Italian author, who published a treatise, about the year 1590, on the magnificence and greatness of cities. He does not mention tea by name, but he describes it in such a manner, that it is impossible to mistake it. "The Chinese," he says, "have an herb, out of which they press a delicate juice, which serves them for drink, instead of wine: it also preserves their health, and frees them from all those evils which the immoderate use of wine produces among us."

The tea-plant is propagated from the seed. Holes are drilled in the ground at equal distances, and in regular rows; into each hole the planter throws as many as six, or even a dozen seeds, not above a fifth part of the seed planted being expected to grow. While coming to maturity, they are carefully watered; and though, when once out of the ground, they would continue to vegetate without further care, the more industrious cultivators annually manure the ground, and clear the crop from weeds.

The leaves of the tea-plant are not fit for gathering until the third year, at which period they are in their prime, and most plentiful. When about seven years old, the shrub has generally grown to about the height of a man, and its leaves become few and coarse; it is then generally cut down to the stem, which, in the succeeding summer produces an exuberant crop of fresh shoots and leaves; this operation, however, is sometimes deferred till the plant is ten years old.

The process of gathering the tea is one of great nicety and importance. Each leaf is plucked separately from the stalk; the hands of the gatherer are kept carefully clean, and, in collecting some of the fine sorts, he hardly ventures to breathe on the plant. At a place called Udsi, in the island of Japan, is a mountain, the climate of which is supposed to be particularly congenial to the growth of tea, and the whole crop which grows upon it is reserved for the sole use and disposal of the emperor. A wide and deep ditch round the base of the mountain prevents all access, except to the appointed guardians of its treasures. The shrubs are carefully cleansed of dust, and protected from any inclemency of the weather. The laborers who collect the leaves, are obliged, for some weeks previous, to abstain from all gross food, lest their breath or perspiration might injure the flavor; they wear fine gloves white at work, and during that period bathe two or three times a day.

Notwithstanding the tediousness of such an operation, a laborer can frequently collect from four to ten, or even fifteen pounds a day. Three or four of these gatherings take place during the season: viz: towards the end of February or beginning of March; in April or May; towards the middle of June; and in August. From the first gathering, which consists of the very young and tender leaves only, the most valuable teas are manufactured: viz: the green tea called Gunpowder, and the black tea called Pekoe.

The produce of the first gathering is also denominated in China, Imperial tea, probably because where the shrub is not cultivated with a view to supplying the demands of the Canton market, it is reserved, either in obedience to the law, or on account of its superior value, for the consumption of the emperor's court. From the second and third crops, are manufactured the green teas called in our shops Hyson and Imperial, and the black teas denominated the Souchong and Congou. The light and inferior leaves separated from the Hyson by winnowing, form a tea called the Hyson-skin, much in demand by the Americans, who are also the largest general purchasers of green teas. On the other hand, some of the choicest and tenderest leaves of the second gathering, are frequently mixed with those of the first. From the fourth crop is manufactured the coarsest species of black tea called Bohea; and this crop is mixed with an inferior tea, grown in a district called Woping, near

Canton; together with such tea as remains unsold in the market of the last season.

Owing to the minute division of land in China, there can be few, if any, large tea growers; the plantations are small, and the business of them carried on by the owner and his own family, who carry the produce of each picking immediately to market, where it is disposed of to a class of persons whose business it is to collect, and dry the leaves, ready for the Canton tea-merchants.—*Parley's Magazine.*

A TRUE STORY.

There lived some years ago, in the town of _____, in Connecticut, a man who was much addicted to the practice of converting his neighbor's property to his own use and benefit without 'if' or 'and.' The clergyman of the town suspecting him of making too free with his hay, had one night concealed himself in his barn with a dark lantern. The thief soon appeared and tying up a large bundle, had just left the premises, when the Reverend owner, instead of bawling out 'You scoundrel you! what do you mean by stealing my hay!' disengaged the candle from the lantern and dexterously applied it to the combustible load. The bundle was soon in a light blaze, and the unlucky fellow, suspecting he was pursued by some person with a light, laid his feet to the ground with uncommon agility. But it was in vain to escape the pursuing fire. The blaze increasing brighter as he ran, seemed to his terrified imagination to come nearer; till venturing to look around to discover the extent of his danger, he perceived to his astonishment, that the stolen hay was on fire. How it came so, puzzled him not a little. But the conscientious guilt assisted his natural credulity, he settled down upon the conclusion that the fire was sent from heaven to admonish him of his transgression. Full of this alarming notion he gave himself no rest until he had gone to the parson, and made confession of his crime, and related the warning from heaven. The Reverend gentleman humored his credulity, under the idea that it might reform his life. He was not mistaken; for the blazing hay made so deep an impression on the fellow's mind, that from henceforth he forsook his evil course, became a valuable member of society, and was united to the flock of the judicious clergyman who had assisted so materially in his reformation. He finally died an honest man, in the firm belief of the interposition of providence in setting fire to the stolen hay. The parson kept the secret till the poor man was laid in the dust, but then even the clerical tongue could no longer resist the desire of communicating so serious an incident.

NOT BAD.—A blacksmith brought up his son, to whom he was very severe, to his trade. The urchin was a most audacious dog. One day the old gentleman was attempting to harden a cold chisel which he had made of foreign steel, but he could not succeed. "Horsewhip it, father," exclaimed the young one: "if that will not harden it, I don't know what will!"

BOSTON, WEDNESDAY EVENING, APRIL 1, 1840.

CATALOGUE

OF

CHOICE IMPORTED PEAR AND PLUM TREES.

JOSEPH BRECK & CO. have received, by the Switzerland, a choice collection of Pear and Plum Trees, selected from the Nursery of the celebrated Chevalier Soulangue Rodin, Jardin du Fromont, near Paris, and embrace some of the finest varieties now cultivated. Those who would like to make additions to their collections would do well to make an early application, as many of the varieties will soon be exhausted.

PLUMS.

- No. 1 Reine Claude Violete.
- 2 " " dorcé.
- 3 Royal de Tours.
- 4 St. Jean.
- 5 Monsieur Hatif.
- 6 " Tardif.

- Red Tankard do.
- Yellow Scotch do.
- White Tankard do.
- Purple Top Hybrid.
- Red Globe Mangled Wurtzel.
- White do do.

We have also received some of the Early Hope Cabbage Seed, which was tried last year at New York and proved to be superior to any Early Cabbage hitherto known in the country.

We have now in New York, which will come to hand in a few days, some of the Chevalier Barley, which we shall be happy to offer to our customers.

It has been understood by some that the seeds were left with us for gratuitous distribution. We wish to correct this mistake as it is not the case. We were directed to dispose of them at a small advance, sufficient to pay for our trouble, storage, &c. **JOSEPH BRECK & CO.**
Boston, Feb. 12, 1840.

STRAWBERRIES.

Those who are desirous of cultivating this delicious fruit are respectfully informed that the subscriber has succeeded, after a number of years experimenting upon the Strawberry, not only in obtaining new varieties, but in ascertaining the best method of cultivation.

Specimens of the fruit grown in his Garden have been exhibited at the Massachusetts Horticultural Society Rooms, the four past years, and are also to be well known in Faneuil Hall Market to need particular notice here.

He has for sale at his Garden, in Brighton, Mass., the following eight varieties of Plants. They are of superior stock and quality, all warranted to be truly named and free from the mixture often found in those offered for sale promiscuously.

Those who are in want of Strawberry Plants, are respectfully invited, and they will find it interesting, to call at the Garden and see the manner of cultivation. The method of cultivation, and any information desired will be cheerfully given.

Warren's Seedling Melon.—A new and valuable kind. A free bearer, fruit very large and juicy; fruit measuring four and a half inches have been exhibited the past season.

Melrose Castle.—Fruit extremely large, high flavored, and showy. Specimens of this kind have been exhibited at the Horticultural Rooms for two years past, measuring five and a half inches in circumference.

Bath Scarlet.—Fruit large, full bearer, and beautiful scarlet.

Early Virginia.—This is considered the earliest fruit—a free bearer, large, and very early; decidedly a fine kind for market.

Royal Scarlet.—Fruit long oval shaped and juicy.

Andalus.—Fruit very large but very numerous.

English Wood.—Fruit well known.

Monthly.—Fruit is gathered from the vines from June to October, and in good quantity and fine quality.

Orders left at the Garden, or directed to the subscriber, Brighton, Mass., or left at Messrs. J. Breck & Co.'s Agricultural Warehouse, Boston, will be carefully and promptly attended to, and all Plants will be carefully packed and forwarded agreeably to directions.

JAMES L. L. F. WARREN.
Nonantum Vale, Brighton, Mass., March 4.

 - New Dwarf Red Solid do.
 - Do White do.
 - Superior Double Curled Parsley.
- For sale by **JOSEPH BRECK & CO.**
February 19.

PLOUGHS.

Constantly on hand, a good supply of Howard's Improved Cast Iron Plough.

This implement, one of the oldest and most useful employed on a farm, has undergone of late years, a wonderful change in all its most essential parts, and has been greatly improved. The Cast Iron Plough is now most generally used among the best farmers, and considered decidedly the best. Among the different ploughs now made of cast iron, Howard's stand unrivalled. They have been used at the different Cattle Shows, and Ploughing Matches, and have in all cases been approved by them. At the Brighton Cattle Show at the exhibition in October, 1832, they received the premium of \$10, awarded as being the best plough presented.

Also, a good assortment of other Cast Iron and Wood-ploughs; With's Improved Cultivators; Chandler's Improved Double Harrow; Lock's Garden and Field Rollers; English Scarifiers; Davis's Improved Patent Dirt Scrapper, &c. &c.

JOSEPH BRECK & CO.

March 11, 1840.

WILLIS'S LATEST IMPROVED SEED SOWER.

STILL LATER.

Willis has made some considerable improvement in his Seed Sower for the present year, making it as complete as last year and hard study can possibly make it. He sold of the last year's improvement, over eighty machines, being all that was manufactured, (and could have sold at least fifty or sixty more had they been made), every one of which gave universal satisfaction. In using this machine, the farmer may be certain that his seed is put into the ground, and at the same time in the best possible manner. There has been a great difficulty in machines for sowing garden seeds: they are very apt to clog up, and the farmer might go over an acre of land and not sow a single seed; but not so with this; it is so constructed that it cannot possibly clog. In using this sower, the farmer can save one half of his seed, and do the work at less than one quarter the expense of the common way of sowing his seeds, and have it done in a much better manner; it opens the furrow, drops the seed, covers it over and rolls them down. It will sow any kind of Garden Seeds; say Ruta Baga, Mangel Wurtzel, Turnips, Carrots, Beets, Parsnips, Onions, &c.

IMPROVED HAND SOWERS.—Calculated for sowing small Garden Seeds, and very useful for the purpose intended. March 11. JOSEPH BRECK & CO.

April 1. JOSEPH BRECK & CO.

SINA SILK WORMS EGGS.

The Eggs of the celebrated Sina Silk Worm, now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The Sina Silk Worm was introduced to France from China by Louis XVI. in 1781, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France.

Each sheet contains an ounce and is signed "Camille Beauvais." Price 8s.

Or apply to JOSEPH BRECK & CO.,
March 25. eptf

Inquire of the Subscriber at South Natick.
March 4, 1840. I. H. T. BLANCHARD.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure. They are also stated to possess the precious property of hatching simultaneously.

He keeps constantly on hand a supply of Ground Bone and solicits the patronage of the agricultural community. Price at the Mill 32 cents per bushel, put up in casks as delivered at any part of the city at 3 1/2 cents per bushel, and no charge for casks or carting.

Also, Oyster Shell Lime, price 10 cents per bushel at the Mill; put up in casks, each at 60 cents per cask delivered at any part of the city.

Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

March 4, 1840. NATHAN WARD.

URATE AND POUURETTE.

The Company known in the City of New York by the name of "THE NEW YORK URATE AND POUURETTE COMPANY" has been incorporated by the Legislature of the State of New Jersey, by an Act, entitled "An Act to incorporate 'THE LODI MANUFACTURING COMPANY,' for purposes of Agriculture—with a Capital of 2000 Shares, each Share \$100, being equal to a Capital of \$200,000.

A Pamphlet has been published containing particulars and very important information to Farmers and Gardeners, a Copy of which may be seen at this Office, or procured from "The City, No. 71 Cedar st., New York.

The particular attention of the reader is requested to the following particulars:

1st. A Subscription for a part of the Stock of "THE LODI MANUFACTURING COMPANY," will be open at the house of Moses Miller, keeper of the Eagle Hotel, in Jersey City, opposite the City of New York, on Wednesday and Thursday, the 8th and 9th days of April, 1840, from 10 o'clock in the forenoon until 3 o'clock in the afternoon of each day, and the payment of \$25 on each Share will be required to be paid at the time of subscribing, (either in Specie, or in Bank Bills of Specie paying Banks.) See Section No. 1 of the Act of Incorporation.

2d. Any person who, if the whole 1500 shares shall be subscribed for, that nothing more than the \$25 may be called in upon this Stock; but if any person chooses to pay the whole amount, he will draw dividends accordingly.

3d. If 500 Shares shall be subscribed for, on the 8th and 9th days of April, 1840, and if it is now ascertained they will be a further subscription of 500 Shares by Farmers and Gardeners exclusively, will be opened at the Office of Dey & Elmendorf, No. 71, Cedar street, in the city of New York, and be continued open 60 days, commencing on Monday the 13th April, 1840, from 10 o'clock in the forenoon until 3 o'clock in the afternoon of each week day, and to continue open until the 20th day of June inclusive, or until the whole of the said 500 Shares shall be subscribed for; and as soon as these 500 Shares shall be subscribed for, the Stocks will be closed. The Dividend on these 500 Shares is to be 50 bushels of Poudreite to each Share, for 5 years, which is equal to 20 per cent per annum, so that at the end of 5 years they will have received back their whole money. See Section No. 6.

The object of the Company in procuring Stockholders is to procure consumers, and therefore they prefer Farmers and Gardeners to subscribe one Share of the reserved Stock, rather than five shares to which each is entitled, and it is believed the other 1500 Shares of the Stock of the Company will turn out equally valuable, but then there is no authority given by law to the Company to guarantee that 20 per cent shall be paid in Poudreite. It is expected that the Dividend on this reserved Stock will be made, half in May and half in September, in each year, and therefore the whole amount of the reserved Stock, say \$100 each Share, must be paid for at the time of subscribing.

4th. Persons disposed to subscribe, may authorize any person to do so for them as follows:

I, of the Town of in the County of and State of Farmer, (or Gardener as the case may be,) do hereby authorize to subscribe my name for Shares of the Stock of the Lodi Manufacturing Company, and pay the monies required to be paid at the time of subscription.

Witness my hand this day of 1840.

WITNESSE PRESENT.

The subscribers are not held responsible to pay any thing beyond the payment required at the time of subscribing.

Any number of Farmers in one neighborhood may authorize one of their number or any other person to subscribe for them.

4th. AGENCIES.—A number of Persons have already been appointed as Agents in different parts of the United States. The Company allow Agents a commission of 10 per cent for their trouble, on the net amount of the cost of the Poudreite.

By the 6th Section of the Act, Farmers and Gardeners exclusively are secured the preference of a bonus equal to \$45,000 over any other consumers. They are secured an annual dividend of 50 Bushels of Poudreite for every 100 dollars they invest in the reserved 500 shares of the Stock of the Company, which at the price the Company have sold and are selling the manures, gives a dividend of 20 per cent per annum for 5 years; after which they divide equally with the other Stockholders. It is believed, however, from data which have been furnished in a pamphlet, that the dividends on all the stock will not be less than 20 percent per annum.

One cent's worth, under the provision of the 6th Section, will insure 100 hills of corn. One gill of Poudreite to each hill of corn in 1839, ripened corn in three months from the time it was planted, so far as to render it too hard to eat as green corn, which would save it from destructive effects of an early frost.

One of the greatest advantages that Poudreite has over every other manure, is the saving of labor in its transportation to the farm and its application to the soil. The saving is one half in the amount of cost, labor and expenses attending the same.

Any Farmer in moderate circumstances who loans his money at 6 per cent. interest per annum, may take one share

in the stock of the Company which would cost him \$100, and receive a dividend of 50 Bushels of Poudreite which would cost him 50 cents per Bushel, and will do his land and crop more good than 50 loads of the best horse manure that would cost him \$50, besides the labor and expense of carting and putting it on the land.

If any person wishes further information on the subject, they will please apply to ANTHONY DEY, either in person or by Letter, directed to him at his office, N. 71 Cedar street, New York.

New York Urate and Poudreite Company.

JOSEPH BRECK & CO. are agents to receive subscription for stock in "The New York Urate and Poudreite Company.

The manures are not divided among the Stockholders, as are those belonging to another establishment, but sold, to applicants, for cash on delivery. Orders are supplied in the order of time in which they are received. Urate 50 cents and Poudreite 40 cents per bushel, with contingent charges for bags or barrels &c.

The material is disinfected and rendered free from offensive smell, by a compound, every part of which is in itself a good manure.

The experience of the past and present years, 1838 and 1839, on Long Island, has satisfied many of the farmers that these manures have the quickest operation upon vegetable matter, producing greater abundance, and the cheapest of any manure they have ever tried.

Amended instructions for their use, the result of practical experience, will be furnished on application. The effect of Poudreite upon Grape Vines and Morus Multicaulis is beyond all cooperation. JOSEPH BRECK & CO., Agents.

March 11.

URATE AND POUURETTE.

JOSEPH BRECK & CO. would inform their friends and customers that they are agents for selling Urate and Poudreite, which will be delivered at their store, at New York prices, with the addition of expense of freight and trucking.

Also—Agents for selling BOSE MANURE and Oyster Shell Lime.

March 11.

AGRICULTURAL BOOKS.

JOSEPH BRECK & CO. offer for sale a great variety of Agricultural books, among which are the following:

Loudon's Encyclopedia of Gardening.

" " of Plants.

" " of Agriculture.

" Salubrian Gardener.

Forbe's Hortus Woburnensis.

Practical Agriculture, by David Low.

Chaptal's Agricultural Chemistry.

Hogg on the Cultivation of the Carnation and other Florists Flowers.

The Florist Cultivator.

Prigden's Gardeners Assistant.

Fessenden's American Gardener.

" Complete Farmer.

Kenrick's Orchardist.

Manning's First Book of Fruits.

Sayers' Fruit Garden Companion.

" Flower Garden Companion.

Treatise on Sugar Beet, by David Lee Child.

American Swine Breeder.

Mowbray on Poultry.

Monography of the Genus Camellia.

Dennis' Silk Manual.

Cobb's do.

Kenrick's Silk Growers Guide.

Whitmarsh on the Mulberry Tree and Silk Worm.

American Farmer.

Parley's Encyclopedia of Botany—The Young Florist.

Weeks' Treatise on Bees.

February 5.

ELEMENTS OF PRACTICAL AGRICULTURE.

Just received, a supply of the Elements of Practical Agriculture, comprehending the cultivation of plants, the husbandry of domestic animals, and the economy of the farm. By David Low, Esq. F. R. S. E., Professor of Agriculture in the University of Edinburgh. Second edition, with numerous engravings; 718 pp. London published. For sale by JOSEPH BRECK & CO., No. 51 and 52 North Market Street.

February 5.

FARM FOR SALE.

For sale, a superior farm of nearly fifty acres, between Boston and Lowell, 15 miles from the former place, on which is situated a convenient dwelling house, barn, and other buildings in good repair, and an orchard of choice fruit trees. For further particulars inquire of the subscribers, No. 52 North Market Street. JOSEPH BRECK & CO.

February 26.

N. E. FARMER.

AN ADDRESS

Delivered before the Middlesex Society of Husbandmen and Manufacturers, at their Annual Cattle Show, Oct. 2, 1839. By HENRY COLMAN, Commissioner for the Agricultural Survey of the State. Published in the N. E. Farmer by request.

Farmers of Middlesex and Fellow Citizens:

Agriculture is the theme of this occasion. You expect me to speak of it. It is for this reason you have honored me with an invitation to address you. Possibly I may speak of it with some measure of enthusiasm. My sense of its importance, in various respects, cannot be increased. I entreat you to hear patiently and judge with candor. It would appear like affectation if I should pretend to any fluency in speaking on this subject; but believe me, I am not wanting in a just sense of my own deficiencies, nor in the respect which is due to the intelligent audience whom I address.

The cultivation of the earth is man's duty and business. He was formed for labor. Labor is the indispensable and inevitable condition of his health, his bodily and mental health, his physical, intellectual, moral energy and vigor. Some have represented the love of ease and repose as a natural instinct. It is no more natural than the love of labor and action. Properly speaking, it is not so natural; and that we easily slide into habits of indulgence and indolence, is the fault of education, of false sentiments concerning the hardships of labor and the value of repose, of vicious cockering in our childhood, and sometimes of the exaction of labor beyond our power, and to an excess which makes it painful. Every young animal, the human as well as the brute animal, finds his chief pleasure in the exercise of his limbs, the expansion of his lungs, and the full display of all his senses and faculties. He delights to run, to leap, to dance, to wrestle. His mind wakes with his body. He is full of thought. He pants with curiosity and inquisitiveness. His imagination gathers its golden treasures every where, from field and roadside, from hill and valley, from the depths of the sea and the profounder depths of the azure ocean in which he floats. The beams of light bear him from sun to moon, from moon to stars. Nothing satisfies him. His mind never cries "enough." He penetrates into the third heavens; and explores a universe, on the gossamer wings of thought. The muscles having once tried their strength, acquire continually increased power, and find relief only in exercise. So it is with the mind: There is between them an electrical sympathy, the chain of which cannot be broken. It would continue so through life, until the light began to flicker in its socket, if we did not undertake, as we sometimes call it, to amend nature, but more properly, to defy and outrage her. We begin by repressing the vivacity of youth and childhood, and utter our solemn rules of decency and order, as though not a motion must be made, unless made in the precise line or angle or periphery of authority. Then fanaticism,

with its lean and lengthened visage, puts on its cowl, and comes upon the green, and tells the boys and girls bryant in the joy of life and youth, that it is a mortal sin to play and dance. Why does he not go to the lambs, and tell them not to skip and play; and clip the wings of the birds; and silence the busy hum of the insect tribe, rioting with ecstasy in the joy of existence, and thus proclaiming the beneficence of the Creator! Then, too, we begin the work of improving the human frame, and cramp it with ligatures and bandages and elastics, which render every healthful effort of the muscles almost agonizing, until use has reconciled us to this vile durance; and distort the joints and repress the rushing tide of the blood, and derange the pulsations of the heart. The feebler sex require a peculiar discipline, and with them the miraculous machinery of digestion is to be compressed and crowded into the smallest space possible, and the body cased so tight in its iron armor, like a chicken trussed for the spit, that respiration becomes all but impossible; and the spine is so crooked and twisted that an upright woman is hardly to be found in the community; and then with a *nonchalance* and a self-complacency ineffably ridiculous, we call the limping Chinese barbarians! This incapacitates us for labor; this destroys all muscular energy; this makes the plow wither; and renders every exertion painful. Then, likewise, we accustom ourselves to speak of labor as an evil, and to talk of rest and ease as a great boon. We compassionate the laborer. We pity his condition as severe. We look upon labor as vulgar, and to be dreaded and disdained. Then, likewise, much of labor is severe. It is the more severe and oppressive, because so large a portion of the community evade their obligations and do nothing, but consume the fruits of labor, excepting that with gracious condescension, not to say, more properly, with insufferable arrogance, they boast of their philanthropy and charity in patronizing labor, by permitting the industrious classes to administer to their pleasures and dissipations, and then paying them out of their own earnings for these services. The fill-horses do the work; they bear the weight; they start the load; they hold back; while many, like the forward horses in the team, wear the bells and wave the nodding plume; and amble and prance this way and the other; but take good care not to rub their sides with the traces, and do not move an ounce.

In the beautiful allegory of Genesis, man is represented as having been placed in a garden, redolent with spicy perfumes, and filled with every luxury which could regale or entrance the senses and charm the imagination. The velvet couch of green sward to recline upon; the gurgling brook to warble his lullaby; the shaded bower to protect him from the noontide sun; days unclouded by tempests; nights peaceful, serene, and spangled; and the earth pouring out its richest treasures, and scarcely demanding that he should stretch out his hands to gather them. This is portrayed in the brilliant language of oriental poetry, as the golden infancy of the human race. But man could not

stay there. I will awaken no painful recollections by alluding to the irresistible seductions which tempted him by an inexcusable disobedience, to forfeit all this luxury and delight. I would offend no man's prejudices; but I understand this as the language of poetry, and suited to point a most important moral. It is evident that man could not endure this condition. He would have sunk into effeminacy under such indulgence. Therefore it was that the Creator expelled him from Paradise, and sent him to till and to dress the earth, and to get his bread by the sweat of his brow. So long as his nature is what it is, the divine Providence could not have ordained for him a greater benefaction.

The cultivation of the earth, therefore, is man's duty and business; made so by his constitution; by the necessities of his condition; and by the appointment of his Creator. Let us not complain of it. Let us thank God, for we have great reason to thank him, that it is so. If we must complain, let us complain as we may with the best reason, of every institution, sentiment, custom of man, and the world is full of them, which prevents or interferes with this great law of his being.

The earth, then, was given to man to cultivate. It must be cultivated or he must perish. All the bread which sustains him comes from the earth, and from no where else. All the clothes which he wears come from the earth, and from no where else. The various professions and occupations in society arrogate to themselves a great importance and an extraordinary and exclusive utility. What a dust we make, said the fly, as he whirled round upon the cart-wheel! We should be sorry to disturb the self-complacency of any of them; but you might extinguish all the commercial and trading community to-morrow; all the merchants, and bankers, and speculators; all the learned professions; all the fancy and ornamental professions and operatives; and the world could get on without them. But without the cultivation of the earth, the whole race of man must become extinct.

Look next at agriculture as the source of wealth. We shall not now entertain the discussion as to what constitutes wealth. We shall not undertake to consider the position, that agriculture is the only producer of wealth. Both these positions, however, are more nearly true than most persons would be perhaps at first willing to admit. These positions are indeed fully true of labor, though not exclusively of agricultural labor.

We admit that all may be called wealth which a man can appropriate to his necessities, to his uses, to his comfort, to his pleasure, to his improvement, or to his ornament. These several ends give a different comparative or relative value to different substances. Their value is also affected by their scarcity, or the difficulty or the ease of obtaining them, and the profusion in which they may be produced. We admit, likewise, that many of the products of agriculture require, besides the labor of production, much other labor to bring them into a condition for use. The manufacturer, therefore, from the turnspit at the fire, to the most delicate

worker of lace, who, in her exquisite workmanship, plies a needle in fineness almost rivaling a pencil of light; to the chemist, who examines the various soils and manures in his crucibles and filters, and explains their needs and uses; to the mathematician, who points out to the farmer in respect to the mould-board of his plough the precise angle of incidence or flexion by which the sod may be elevated and turned over with the least power of draught, and placed in the position in which it is desirable it should be laid, so as to expose the greatest amount of surface to the light and air; and to the philosopher, who calculates the planetary changes, and instructs the farmer as to the times and seasons of his various operations—all may be considered joint laborers in producing the means of subsistence and in fitting them for the use of man.

But none of these considerations affect the fundamental position that agriculture is the great source of wealth, of individual and of national wealth and power. Look around you, and of the things which you call your own, which you use, which minister to your pleasures or your comfort, what a vast proportion of them are the direct products of agriculture. Look at your tables, and what is there that you eat or drink, save the simple beverage of nature, which does not come from the field? Look at your dress, and what article either of comfort or ornament, of necessity or use, which is not the direct product of agriculture? Even the silken fabric, so bright, so fine, so beautiful, so brilliant, in its changing colors reflecting the gorgeousness of an autumnal sunset, and the plaited straw of the most exquisite fineness and finish; and even the paper of your books, radiant with the visions of the imagination, or beaming and burning with the flashes of genius and eloquence, what are all these but the products of agriculture? Ah, indeed, how is philosophy itself to subsist, how is the machinery of thought to go on, how is eloquence itself to pour forth its gushing and blazing torrents, without the products of the earth?

What constitutes national wealth? What are commerce and trade and manufactures all concerned with but the products of the field? A single article of the produce of southern agriculture is rated this year at 80,000,000 of dollars. But vast as this value of the cotton crop may seem, it is little compared with the value of the wheat and the corn crop, and the amount of vegetables and grasses, of dairy produce and of pork and beef and wool that are required and produced for the use and trade of the country. It is impossible to come at any exact estimate of these matters; but every individual may approach an estimate by considering what is the expense of cotton to him in the year, compared with other expenses incidental to his clothing and subsistence.

We have, it is true, in modern times invented another mode of increasing national wealth, and that is by the creation of bills of credit, bank notes, promises to pay.—Many of us are simple enough to believe that we grow rich just in proportion as we multiply and can circulate these promises to pay. Now, I admit, that to a certain extent and within rigid limits this may be a wholesome operation; but is it any actual increase of wealth? Does a man grow rich in proportion as he multiplies his promissory notes of hand? In private life, this would be deemed an *Irish* way of getting rich; in associations it does not differ from this. I mean where it is mere credit; not resting upon actual accumulations, nor based upon prospective results,

which are as certain as any thing future in human calculations can be. But when these promises to pay are once made, who is to pay them? If they are ever paid at all, it must be by the hand of productive labor—by the products of the field or the sea. If productive labor does not make them good, they will never be good for any thing. Every bill of credit that is issued is an assessment upon the industry of the country. It would have been well for the public had they seen this before they incurred the tremendous losses which they have already suffered. It would be well if they could see it now in season to guard, as well as they may, against the tremendous explosions which must accompany the extravagance and reckless extension of a system fraught with innumerable evils to the honest industry of the country, and adapted to frame the prodigal idler's palace out of the laborer's bones!

But when will men learn any thing from experience? What we call the public is a long-eared animal. The crafty understand him. They go into the pasture with their measure of oats, the same decoy which has caught many silly animals before him, and shake it before his eyes, holding the bridle behind their backs, and coming up the blind side of him, before he can touch his nose to the grain he finds the bits in his mouth. Then it is all over; and he must take patiently the whip, which sometimes at every stroke brings blood, if he attempts by rearing or kicking to throw his rider.

The manufacturer leans upon agriculture as their main support. Who turns these thousand spinning jennies, in gyrations which no other Jennie, not even a Vestris or Celeste, could ever dream of rivaling? Who moves the power wheel, the mighty mammoth, which revolves in thundering circles in his subterranean cave, hoary with the glittering jewels that trickle from his crown, and pour themselves down his sides? It is his noble sister; the elder sister of the household of industry, Agriculture—without whose aid and bounty all the operations of the family must cease at once.

Take that most beautiful of all artificial creations, the combination of the noblest triumphs of human art, that magnificent sea-bird, a gallant ship, with her wings spread to the favoring gales, floating in silent majesty over the crested wave, dashing the glittering gems from her sides, now calmly mounting the heaving surges, and now gracefully plunging into the azure valleys, fearless alike whether the zephyrs make her masts their lute, and utter their sweetest notes among her strings, or whether the tempest, pouring its violence among them, causes her spreading wings to echo and re-echo its voices of thunder—look, I say, at this beautiful, this grand object, when she leaves your port to explore many a trackless sea, and to carry your sympathies into lands many a sun's journey from your own, and ask yourself, what are her timbers, her masts, her sails, her ropes, her supplies, her cargo—but the products of agriculture? and how could they who build, and they who load, and they who navigate her, live a day without these products?

Agriculture, under God, is a creator. She speaks and it is done. She stretches her mighty wand over the earth, and countless beautiful and glorious forms rise at her bidding. She casts the seed into the ground; perhaps it is the least of seeds; but see how soon it becomes a tree, and its branches are glittering and pendant with fruit. What amazing miracles does she work before our eyes! With

what a boundless profusion does she compensate the labors of industry and skill! What marvellous products does she pour out, in fifties, in hundreds in thousands! The product of a single grain of wheat in a single season, was ascertained to be 21,109 ears, measuring three pecks and three quarters of grain, and producing no less than 376,844 kernels. What instrument secondary to the Almighty agent, is a creator like agriculture? and what is all the real, substantial, useful wealth of the community but its products? The agriculture of a country is the great source of its riches, and the right arm of its power.

Consider agriculture as a profession or occupation. I do not wish to speak invidiously of any of the occupations which society permits. I arrogate to myself the keeping of no man's conscience; and it is employment enough for each man to take care of his own. There are men living without any occupation whatever. Is this honorable? Is it a *honest* mode of living? I would not ruffle, even with a feather, the smooth waters of this day's festivity; and therefore I shall not say what I think of such a life as this. There are men who live upon the vices and corruptions of other men; vice and corruptions which they themselves help first to produce. These are the carrion birds of society, to whom the more putrid the carcase of their victim becomes, the more and the sweeter the gust with which they seem to hover round it. Need any thing be said of professions which require, at their inevitable price, the sacrifice of what ought to be far dearer to a man than his life, I mean his self-respect, his conscience, his moral nature and dignity? There are professions in society whose tendency is to absorb the whole soul in the pursuit of mere pecuniary gain. There are professions which tax all the powers of body and mind to minister to mere frivolity, show, fashion, and parade. There are professions and occupations, where days and nights are dragged out in never-ending toil, in the noisy streets or the subterranean hiding places and vaults of cities, where the glorious sunrise and sunset are never seen; and where the balmy air of heaven, as it sweeps over the green and dewy fields, is never breathed; but only pestilential vapors of a thousand commingled and detestable odors. There are professions called learned and honorable professions, too often the object of a mistaken envy; for they are full of headache and heartaches; of feverish days and sleepless nights; of sorrowing bosoms and throbbing temples; and deeply cankered and poisoned by avarice, and envy, and ambition, and the lust of power and the hatred of competition, and the chagrin of disappointment; and the countless evils which the inexorable and capricious tyrant, public opinion, whose bond slaves they are and must be, has always at hand to pour out of his Pandora's box.

Physic is an uncertain practice, where few can tell whether they kill or cure; where doubts hover in thick clouds over the reflecting mind; where an experience increases, distrust of one's own skill and the power of medicine itself it crosses; where uncorrupted modesty and incorruptible integrity shall often go feeless, when quackery shall change its labelled and gilded pill-box into a coach and four and where to be an "Indian doctor," or a "blind doctor," or a "rain water doctor," or to be an old woman and descended from the seventh son of some seventh son, or, better still, not to have been born at all, and to have had neither father nor mother, but perhaps to have come into the world as was

said of one. "By the force of vegetation,"* is likely to prove a better introduction to a wide and successful and profitable practice, than to have spent days and nights and months and years in studying the human frame, in watching the aspects and progress of diseases, and gathering knowledge and skill in the painful and disgusting but benevolent and useful offices of dissecting rooms and hospitals.

Law is a profession full of study and labor, of perplexing difficulties and subtleties, which are sore entanglements to the conscience; busied, in too many cases, about little else than the chicaneries and vices and tricks and crimes of the unprincipled and profligate; where a man sells himself to his client—perhaps the greatest villain unhung—soul and body; and where, after he has committed himself to his cause, it must be his great business to study what advantage he can take of his adversary; or to creep stealthily in the dark and see if his opponent has left his garden gate open or his door unlatched; or if perchance he has dropt asleep on the edge of a precipice, that whether innocent or blameable, he may shove him over; and then, if by any art or skill he can untie the net or break the meshes of the snare in which his client, whose name he knows is Legion, is caught, and set him free again to prey upon society—why then he has done only his duty; if such a course, by any honest rule of morals, can be dignified with the sacred name of duty.

What shall we say of theology, I mean sectarian theology; for a minister must be sectarian or partisan, or he will have few friends. Sectarian theology is generally a muddy pool, where the deeper one plunges the thicker it becomes, until perhaps he loses himself in the bathos of metaphysical subtlety and jargon. Here, if a man is simple-hearted, and frank and cheerful and playful, and does not go about in the world with the face of one who has just risen in his grave clothes, and when you offer to shake hands with him, does not deem it necessary to prove his dignity by putting into your warm grasp a bundle of icicles, people will say he is not serious; and when Sunday comes, before he can preach, like an honest man, on righteousness, temperance, or judgment to come, perhaps he must look out of his window at the vane of his church and see which way his people have determined the wind shall blow that day; or else, if he is not John Rogersized, his crying children shall have no more bread and milk from that magnanimous people. I ask, what attractions has such a profession, thus servilely dependent on popular caprice, likely to have with an honest and independent mind?

What shall we say of politics as a profession?—a game full of uncertainties; where to-day men shout hosanna, and to-morrow there is none so vile as to do you reverence;—where in general all is as heartless and hollow as heartless and hollow can be; where every man is for himself, or for the public, if the public is for him,—and where, in the race of competition, like shipwrecked sailors in a storm, they will shove their own friends and companions

from the same floating fragment, if in any respect they endanger or impede their own arrival at the shore; where men, however honorable their purposes, and high-minded and upright their conduct, must come before the public as a target to be pelted and shot at with missiles as vile as those who send them; and where if you break or slip the collar of party, though it may chafe your neck so badly, that "the iron enters into your soul," then the hounds are unleashed upon you, and will hunt you to the death without favor or pity.

The profession of agriculture bears with it none of these evils. If there lives the man who may eat his bread with a conscience at peace with man and God, it is the man who has brought that bread out of the earth by his own honest industry. It is cankered by no fraud—it is wet by no tears—it is stained with no blood. The profession of agriculture brings with it none of those agitating passions which are fatal to peace, to satisfaction, or to the enjoyment even of the common blessings of life. The profession of agriculture presents few temptations to vicious indulgence, and removes a man from those seductions by which too often in other situations, health and character and peace are sacrificed. The profession of agriculture is favorable to health, and to long life, to habits of industry and frugality, temperance and self-government, to the cultivation of the domestic virtues, and to the calm and delicious enjoyment of domestic pleasures in all their purity and fullness.

Allow me to speak of agriculture in the next place in its aspect of utility and beneficence. In this respect, as far as its power extends, no profession goes before it. The man who does what he can to multiply the productions of the earth, labors most effectually at the advancement of the general welfare and comfort. The more bread, the more meat, the more wool, the more flax are raised, so are the necessary supplies of life cheapened, and the more comfortably are the poor fed and clothed and lodged and sheltered; the more are early marriages promoted; and then the more are the ties of social life strengthened; the more are the domestic virtues, the virtues of all others most conducive to man's happiness and his moral improvement, formed and encouraged.

What a means of imparting pleasure is an improved agriculture. How many charming examples present themselves among us of improvements which every eye gazes upon with unmingled delight. Let a man according to his power, take his ten, his twenty, his fifty, his hundred acres. Let him comb the hair and wash the face of nature.—Let him subdue, clear, cultivate, enrich, embellish it. Let him smooth the rough places, and drain the wet, and fill up the sunken, and enrich the barren. Let him enclose it with a neat and substantial fence. Let him line its borders and roadsides with ornamental trees, and let him stock every proper part with vines and fruits. Let his fields and meadows wave with their golden harvests, and let his hills be covered with the herds, rejoicing in the fulness with which his labors, under the blessing of God, have spread their table, and who, when he goes among them, hasten from all sides to meet him, and gratefully recognise in him a friend and benefactor, and lick the hand which is accustomed to feed and fondle them. Here now let us see the neatly painted cottage with its green shades, its piazzas trellised with vines, its sides covered with the spreading elm or the flowering acacia, with here and there the beautiful fir to shade the picture, and the mountain

ash, showing its rich clusters of crimson fruit among the deep green foliage, and the smooth and verdant lawn, stretching its soft and beautiful carpet in the front view; then look again, and see the parents at the close of day, resting from their labors and enjoying the calm evening, with the pledges of mutual and devoted affection rotating before them in all the buoyancy of youthful innocence and delight; and if at such an hour as this, you can hear the hymn of grateful praise rising from this humble abode of peace and love, and its charming notes mingling with the music of the gurgling brook that flows near by, or broken by the occasional shrill and hollow notes of the gentle and fearless birds, which deem themselves loving members of this loving household,—if then, whether traveller or sojourner, your heart is not touched with this charming and not unusual picture of rural felicity, cease to call yourself a man. If still you sigh for the bustle and the noise and the confinement of the city, with its impure water, with its offensive odors, with its despicable affections, with its heartless formalities, with its violent excitements, with its midnight festivities, with its utter destitution of sympathy, with its low estimate of human life, with its squalid poverty, its multiplied forms of wretchedness and crime, its pride, its vanity, its ambition, its pomp, its servility; then go back into your gilded prison-house, and to pleasures which an uncorrupted and refined taste, accustomed to drink in the free air of heaven, and to appreciate its freshness, its purity and its salubrity, will find no occasion to covet or envy. The man who by his cultivation and good husbandry presents such a picture to the passer-by, shall he not be called a benefactor to the community? Has he not done much to improve and bless society by his example? Has he not built a monument to his own honor, more eloquent than the sculptured marble?

I have already anticipated, in some measure, much that I designed to say of agriculture as matter of taste and of science; and of the profession of agriculture in its moral and religious character.—As matter of science and as concerned directly with the profoundest intellectual investigations, I know few pursuits of practical life that should take a higher rank. Botany, geology, chemistry, natural philosophy, in all its departments, vegetable physiology, comparative anatomy, the propagation of fruits, the improvement of plants and animals, the changes of the nature of plants by art, the habits of animals, of birds, insects and reptiles, the influences of meteorological changes, the mechanical construction of implements of husbandry, the influence of other arts upon the rural arts, the political economy of agriculture, agricultural education, agricultural improvement, are all matters of science, all having a direct bearing upon, and an immediate affinity with agriculture. The art must remain in its infancy until all these subjects of science are studied and applied in their connexion with it.

As matter of taste agriculture presents scope and demand for the exercise of the most refined sentiments. The farm offers a field for the embellishments of taste in the construction of buildings, in the laying out of grounds, in the leading of water courses, in the arrangement of the garden, in the planting of trees, in the cultivation of flowers, so as to combine and embody the highest efforts of the graphic art. As yet ornamental farming has made little progress among us. In Europe it has become a study and has engaged the attention of some of the brightest intellects. Your own county

*The following is an inscription on a gravestone of a man much esteemed by his neighbors, in Edgartown, Mass. which shows that there is no limit to the eccentricities of the human mind. We cannot say much for the poetry of the sentiment we say nothing. It was inscribed upon it by a direction in his will, and made indismissible upon his heirs.

"By the force of vegetation
I was brought to life and action.
When life and action that shall cease
I shall return to the same source."

presents almost the only examples in New England where it has been attempted on an enlarged and liberal scale; and the munificent proprietor of one of these beautiful establishments has set an example of tasteful embellishment, which though it can be followed, if followed at all, only at a very humble distance by the great body of our farmers, has already imparted a large amount of gratification to the crowds who have been permitted to visit these highly improved grounds; and cannot fail to exert a beneficent influence upon the public taste, and extend its effects far and wide, though the sources of this influence may not be always directly traced.— Wealth cannot purchase for itself cheaper or farther reaching or less exclusive means of embellishment than in these rural embellishments, which bring a double compensation in that the more they are enjoyed by others, the greater the pleasure which the liberal owner himself finds in them.

Of the moral and religious influences of agriculture, I have left myself but little space to speak. Certainly if there be any thing suited to impress the mind with the sentiment of its dependence upon a divine Providence, if there be any thing to make man feel the presence of God near him and always with him, if there be any thing to reveal to man the wide spread and unstinted bounty of heaven, it is the operations and the results of agriculture.

What a humble ministry is that which man performs in the cultivation of the earth; and yet what wonders follow the exertion of that humble agency! Who can remark the changing seasons, the miraculous influences of dew and frost, of heat and light, of rain and snow; who can watch the germination of the seed and trace the progress of vegetation, from the bursting of the dry kernel to the gathering of the ripened sheaf; who can remark the infinite multitudes of animated existences, and the diversities of their form, organization and condition, all sustained by the products of the field; who can reflect upon that bounty which takes care of all, and from the products of the earth daily spreads a repast for every thing that lives, so that not one is sent empty away; who can see all this, and fail to lift up his soul, with grateful adoration, to an all present but invisible Benefactor, and see "God in all and all in God."

Such, my respected audience, are some general remarks which I have taken leave to address to you as not inappropriate to the occasion on which we have assembled. They are perhaps less practical than you may have felt a right to expect; but I shall have other opportunities of supplying this deficiency. I might have illustrated them by facts and examples without number, but I have already, I fear, occupied too much of your time. I wish most earnestly that by any efforts of mine I could produce, especially with the young, a higher appreciation of the honor of the profession, and of the value and dignity of agriculture as an art and a science.

It has indeed small pecuniary advantages to commend it; yet it is not without its profits. It never refuses an ample compensation and an honorable support to well-directed and intelligent labor, and exemplary sobriety and frugality. Its gains are small but sure; and it is secure from those violent risks to which all commercial and trading pursuits are always exposed, and by which so many fail.—Fortunes in agriculture are not to be made sudden-

ly; and to those who are accustomed to hear of an independent estate coming as the profits of a single voyage or a single speculation, and to those who choose only to reckon by their tens and their fifties and their hundreds of thousands, agriculture must be looked upon with disdain. Yet agriculture in New England, in instances which every where meet our observation, is the source of an ample and comfortable subsistence, and as often the foundation of a competence and independence in advanced life as certain and sufficient as a well-disciplined mind can desire.

The profession of agriculture is often contemned as vulgar. Vulgarity is too often its concomitant, but it has no necessary or essential connexion with it. Much has been done to get rid of the vulgarity which has been too justly complained of with farmers by getting rid of those filthy, useless, and detestable habits, tobacco chewing and smoking and rum drinking. The general improvement which has already taken place in the houses and premises of many farmers by the disuse of these vile articles is great, and in the interior every where perceptible. May the great revolution go on in improving and elevating the character of our rural population.

As education likewise advances, the character of farmers must become more respectable and honored. Education is particularly important to the farmers, not merely as exalting their profession, as giving them the influence which as a class they ought to claim in the community; but especially as furnishing a needed and delightful resource in days when the labors of the field must be intermitted, and in the long evenings of winter. There is in truth no condition which among us affords a more favorable opportunity for intellectual improvement and cultivation.

To the successful and happy pursuit of agriculture as a livelihood and profession, we must first of all things bring our desires within the healthful limits of sobriety, and acquire such habits of industry as shall make work a pleasure. When thus entered upon and pursued, no profession, no condition of life affords, under the influence of sound judgment and religious principle, a fairer chance of earthly happiness, better opportunities of sound mental improvement, and a condition of more respectability.

New England, our beloved New England, presents the means of this rational rural felicity in rich profusion to all her sons and daughters, who will avail themselves of their advantages and perform their own part well. Its rough climate, though so often reproached, is in the highest degree favorable to labor and to intellectual power and improvement. The condition of society in New England is full of advantages for rural enjoyment. May her children continue to love and honor her.

Her soil is hard, but it may be made eminently productive. The winters are long, but the time of labor is in this way curtailed, and a better opportunity presented for the cultivation of the social affections, the interchange of delightful sympathies, and the general improvement of the mind. Her social institutions, her churches, her school-houses, and the general advancement of education, all favor her agricultural condition and progress.

The mechanic arts in her borders have reached an extraordinary success. May the sister arts of agriculture and horticulture still advance on her soil with the rapid strides of a few past years, until every hill-top and every valley of her picturesque territory is enriched and adorned by their skill and

taste. You have met here to-day to celebrate the innocent festivities of these beautiful arts; and to bring offerings of the rich fruits and the gay flowers of your cultivation to that Gracious Being, who has most signally blessed us in our gardens and fields. Thank him from your hearts for his wonderful, ceaseless, and unstinted bounty. Speed the plough and honor the cultivator of the soil. Let every blessing upon your labors attach you the more strongly to your homes; and remember that the best return we can make for the extraordinary beneficence which distinguishes our condition, is to enjoy with innocence, to improve with diligence, and to impart with liberality.

For the New England Farmer.

THE INDIAN CORN CROP.

MR. EDITOR—In every country there is an adaptation of soil and climate to some particular crops which may be cultivated with more certainty of success than any other crop. The prosperity of the farmer very much depends on the selection of plants which are indigenous in the country, or proved by long experience to prosper and mature in the soil and climate as the leading objects of his attention. In New England, too little attention has been given to this subject, and our agriculture, in many instances, like several other branches of business, has been carried on amid so rapid and expressive transitions in the objects of pursuit, that numbers have exhausted their capital, and without looking at all into the indiscretions of their course, have endeavored to cast all the reproach on soil and climate; ascribing to good mother earth all the whims of a capricious or avaricious step-mother. The proper remedy of this serious evil may be found in reflection, inquiry, and discussion. We anticipate highly beneficial results from the weekly discussions in the State-House this winter, and have been particularly interested in that on the subject of Indian corn. We think this discussion of more than ordinary importance at the present time, because several unfavorable seasons and some gales of wind have disheartened many of our farmers, and inclined them either to abandon the crop, or assign it a very subordinate and neglected place in the annual course of cropping. And, even some professed theorists have in direct terms encouraged this neglect, saying, we had better attend to other crops, particularly in the vicinity of the city, and import our Indian corn. We have no patience with such recommendations, for we firmly believe there is no more occasion to import corn into Massachusetts than there is to import granite, which we are annually sending in large quantities to distant states. We think the transition course, which has produced most of our depressions and difficulties, is the moving cause of these vast importations of corn into this commonwealth, the aggregate amount of which no one can view without surprise, and some serious apprehensions of the ultimate effects. In asserting that our soil is capable of producing, and that our farmers ought to raise all the Indian corn used in the state we are not presenting merely theoretic positions; we have that best kind of evidence, experience, in the case. Our agricultural course commenced in 1802; it has been pursued ever since, almost exclusively by the aid of hired laborers. Till 1816, the most disastrous year to the crop of Indian corn we have ever known, in imitation of neighbors, we

had been in the habit of purchasing southern corn for animals, and to accommodate laborers. The impossibility of proceeding in the accustomed course during that year of scarcity; the sufferings witnessed, and in our view the unreasonable panic that had seized the minds of so many farmers on the subject of planting corn, induced us to change the course of proceeding. Contrary to general impressions of propriety, we determined to plant more extensively, and apportion domestic animals to the amount of crops. We believe Providence and our own soil the surest sources of dependence. Success under the change far exceeded expectation: domestic animals have been increased, laborers often compensated in native corn, and in some years considerable quantities sold for cash. Now if so much can properly be done by a man who hires all his labor, should not the farmer who daily works with his own hands raise a surpluse of corn every year for the market?

Some reader may think those who hire their labor have generally other sources of income beside the farm, and that the raising of corn after all is a losing business.

This was the confident opinion of some of our neighbors a few years since, and we were induced to put the thing to what we considered an unquestionable test. We weighed the whole crop, allowing 75 lbs. in the ear to make a bushel; we then estimated the corn at 75 cents per bushel, one fourth less than the value, and found without any consideration of the fodder, the corn in the crib would more than pay for all the labor bestowed on the farm, and considerable was accomplished in that year of what we call permanent improvements. It was an unusually favorable season for corn. A similar result could not be reasonably expected in a succession of years. At a just valuation, however, we are confident Indian corn will prove one of the most profitable crops to the farmer, more than nine tenths of the years in which it is planted.

If the representation we have made of the importance and profit of a crop of Indian corn be in any measure correct, the cultivation of this plant is a subject of great interest with farmers, and they should endeavor by interchanges in views, by inquiry and reflection, to ascertain the best methods of culture, and by all the means within their power promote improvements in so good a work. We give some sketches of our experience and practice, not on the idea that we have made advances beyond other cultivators, but rather as our acknowledgment of the debt we owe those enlightened and patriotic men, who have kindly favored the public with accounts of their practice. We began with planting in hills three and a half or four feet apart each way. The corn was dropped on a shovel full of barn manure, five kernels in a hill, with very little attention to location. In dressing the corn, laborers were directed to draw the mould liberally towards the plants; when the dressings were completed, each hill was nearly as large as a bushel. All this was done in accordance with general management, and our first admission of error was in the effects of strong winds on the plants. The earth was raised nearly as high as the first joint of the spire; the wind operated with almost the power of the lever upon it, and in certain stages of the growth numerous spires were destroyed. The practice of forming large hills was gradually abandoned, and the benefits were so manifest both in the greater safety of the plants and their more vigorous growth, that we at length requested the la-

borers to leave the fields after all the dressings effected enough for mowing. This has often been observed and without perceptible injury to the corn crop.

Some dry seasons convinced us the practice of placing manure directly under the corn is wrong. Plants so manured, wilt much sooner under the influences of the sun, and when this effect is produced a succession of weeks, there will seldom be more than a crop of stalks. And even if no drought take place, it may be reasonably doubted whether a crop of corn will be at all increased by planting directly on manure. The influences of it when thus placed are manifestly the greatest in the first of the season, when the corn requires the least nourishment. At the time when the ears begin to form, and an abundance of food is wanted, the energies of the manure begin to decline, and a large portion of the ears set in the stalks never reach maturity. Whenever manure is applied to this crop, it should be in such manner that the greatest influence of it will be felt in the last of the season. Evenly spread over the surface, and lightly covered with a harrow or cultivator, is probably as good an application of manure as we can make, without we submit to the expense of a top dressing about the time of the third hoeing, which would be very efficacious. Where circumstances will admit of such a course, we think it best to make the land sufficiently rich two or three years before the corn is planted. English mowing land, which has been liberally dressed with compost manure a succession of seasons, is a favorable situation for corn. The sward should be turned over as evenly as possible, then the new made surface thoroughly pulverized with the harrow, cultivator, and roller; after these operations, the corn may be planted. It will appear rather feeble and unpromising when it first springs up, but will continually increase in vigor with the progress of the season, and yield more bushels to the acre than we have ever obtained under any other management.

We have supposed that manure furnishes too much food for the corn in the early periods of its growth; in the language of farmers, forces it; when there is only the soil to feed the plants and this has been made sufficiently rich, the food is evolved in an increasing ratio through the season, and an abundance of it is imparted at the critical period with corn.

If corn be planted in hills, we think three feet quite a sufficient distance in well prepared fields; but our success has been greater when the planting has been in drills, the rows three feet apart, and the kernels in the rows about nine inches. It is attended with some difficulty to reconcile laborers to this method of cultivation, but after a few days it will become easy, and they will take only a little more time in dressing an acre than they would in hills. And the product will be greater both in corn and fodder.

At the first hoeing we pass a plough as near the left hand row as possible, without disturbing the plants, turning the mould from the corn; returning we pass it in the same manner by the next row, forming a ridge between every two rows as high as the plough will make. This the laborers leave undisturbed, their business is to destroy weeds that have sprung up, and loosen the mould round the spires of corn. At the subsequent hoeings the cultivator is used, and in passing twice it effectually levels the ridge between the rows; the hoe is used as at first, only to pulverize the earth near the

corn. We are careful in the selections of the most perfectly matured corn for seed, and prefer taking from the most fruitful spires.

In the management of the corn crop the last of the season, we have established no uniform practice; in seasons of drought we sometimes take the top stalks to feed the stock; when threatened with early autumnal frosts, we cut at the ground and stack the corn. We think it best when there is a fair prospect of favorable weather, to leave the crop in an unmatulated state to ripen in the field.

CAUSES OF DEGENERACY IN PLANTS AND ANIMALS.

"And God said, let the earth bring forth the living creatures after his kind, cattle and creeping thing, and beast of the earth after his kind; and it was so."

The instinct of all animals prompts them to select the sweetest, the most nutritious, and the best pasturage, leaving that which is coarse and sour, and particularly avoiding every thing which comes under the denomination of weeds. A constant repetition of this procedure prevents the best description of grasses from spreading and extending themselves by means of their seeds which are prevented from ripening, while the weeds and inferior kinds of plants not offering a sufficient temptation to prompt their destruction, grow, flourish and ripen their seeds, which are annually dispersed, and give rise to new generations of their progeny. This is the cause of the running out of the finer and better kinds of herbage, and of their places being so copiously supplied by pernicious and worthless intruders. Many people entertain a very erroneous opinion on this subject, and suppose that *naturally* there is a constant tendency to deterioration from good to bad, and from bad to that which is worse; when the fact is, that the good is carefully selected and consumed, and the bad suffered to remain unmolested to propagate their kind. One of the best remedies for this state of things is, to sow grass seed thick and of various kinds on the same field, so as not to leave any unnecessary room for unwelcome guests; keep your table full of hidden guests, and fewer intruders will thrust themselves in amongst them. If the weeds were cut off or exterminated as they grow up, and not permitted to seed, and the valuable grass protected so that it could propagate its kind, it would be found to maintain the ascendancy so long as it could procure nutriment to sustain it.

Many farmers are constantly pursuing the same system with their stock which their stock is pursuing with their grass; selecting out the best for consumption or sale, and propagating from the more inferior or worthless specimens that remain; and the result is the same; a constant down-hill progress, from bad to that which is worse; and hence they very unsagely conclude that there is in the *natural* progress of the animal and vegetable kingdom a constant and invariable tendency to degeneracy. "Look nature through," and you will see that like begets like; and if the desire is to improve stock, always propagate from the best and most perfect specimens; those that arrive at early maturity or take on fat most rapidly, or acquire the greatest value in the shortest time, being generally to be preferred.—The laws of nature are unchangeable: from bad comes bad, from good, good: according as thou sowest so shalt thou reap. JACOB.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, APRIL 8, 1840.

POULTRY MANAGEMENT.

ROADBURY, Mass. April 3, 1840.

To the Editor of the New England Farmer:

DEAR SIR—In the last number of your valuable periodical, I noticed an article upon "Poultry Management," over the signature of Mr Thomas P. Hunt. Some of the suggestions contained therein are new, and (as the author has been kind enough to observe, that "my father's remarks will be cheerfully made when requested.") I have taken the liberty of proposing a few inquiries on the subject, most of which have been elicited by the communication above referred to. By giving them a place in your journal you will very much oblige one interested in the subject.

1. Mr Hunt says, "never let your roosters run together." In a large poultry-yard, how can it be avoided?

2. Should their "animal food" be cooked or given them raw? In what quantities, and how prepared?

3. What temperature is requisite to keep fowls warm in the cold season, and at the same time be healthy?

4. What degree of heat is required to raise chickens successfully, in "a room warmed by a stove"?

5. What should be the size of the room say for 200 chicks hatched on the same day, and would so many do well together?

6. Would it not be well to put one old hen in the room at the time the chicks are placed there?

7. What should be the furniture, &c. of such a room, and how should it be arranged for the best advantage?

8. How soon after hatching should the chicks be taken away from the hens (to be raised in this manner,) and what disposal should be made of the mothers?

9. How long would it be well to confine the chicks in the room?

10. Why are not sugar beets, carrots, ruta baga, or other roots, when boiled or steamed, good food for poultry?

11. How long does the "moulting season" continue?

12. Are the "Creole" fowls a native breed, and can they be obtained? What is their color and particular shape?

13. Where can the "Booby" fowls be purchased?

My stock consists of about two hundred, and the breeds are the Poland, Dorking, Surrey, and Malay, with a few Creepers and common fowls. To the first named I give the preference.

Respectfully,

T. W.

We publish the above queries, and hope we may hear from our friend Hunt in reply. As he is now in Pennsylvania, this cannot be immediately expected. We regret that we cannot fully answer the questions of our correspondent at once.

In respect to the 1st question; we believe it would be impracticable, unless there are enclosures or yards which are completely fenced and secured from intrusion.

2. To the second question, their food may be given them either in a raw or cooked state. It is generally preferred in a raw state. The amount cannot be prescribed, but they may be fed with liver or coarse pieces of meat occasionally. Some animal food is indispensable to their health.

3. Artificial heat can only be necessary in intense cold.

Let the hen-house be faced to the south, and thoroughly closed at the back side; let it be glazed so as to admit the sun; let the entrances be near the ground, and in winter not numerous, and capable of being closed at night, and the roosting places so that they can sit together; and they will be comfortable enough.

4. After the first few days 45 to 50 deg. will be warm enough.

5. 20 ft. by 30 ft. and 15 ft. in height would be ample. The floor should be the ground; and cleanliness is highly important; so also is fresh air.

6. It is not necessary. A celebrated poulterer near London, had some stables of hens made of wood, with their wings and bodies covered with flannel or woolen, under which the chickens nestled. These are said to have answered very well.

7. If for chickens exclusively, nothing but roosting places and inclined steps to reach them are needed, with the wooden mothers above referred to and a watering tub. If for a poultry house to which ingress and egress may be free, boxes to lay in and poles upon which to roost.

8. The mothers will dispose of themselves. The chickens may be taken away at a week old, if due provision is made for their comfort. Excepting in cold weather, an open yard is much preferable for them to range in at pleasure than confinement in a covered building.

9. According to your discretion.

10. Do not know of their having been tried—but probably not comparable to potatoes.

11. Two to three months in autumn.

12. Cannot answer. The best fowls for the production of eggs which have come within our knowledge are the Sicilian; a dark colored, full sized fowl, with a towering plume.

13. Know boobies enough, but not of the feathered tribe. A friend has told us that he found at Head's table in Philadelphia on one occasion a pair of fowls weighing 17 pounds, and that Mr Head said they were common in that market. These we should think were the "Great Boobies." They were probably originally from Calcutta. We have had of this kind, which we suppose may be the Malay, referred to by our correspondent. The roosters of this tribe must not be placed with our common fowls.

We are inclined to believe that the Poland hen is the same with the Sicilian.

We trust our friend Hunt will answer in due season, and with all his learning and experience. We throw out these hints merely as an apology for an answer.

H. C.

Boston, 2d March, 1840.

To Benjamin Guild, Esq., Corresponding Secretary Massachusetts Agricultural Society:

DEAR SIR—At the request of some of the Trustees I submit to you some account of the process adopted by Mrs Harriet F. Blake, on the farm of Geo. Denny, Esq., Westboro', of making butter, a sample of which I had the pleasure of submitting to the Board at their last meeting; and a small sample of which I send to-day.

The cows, as I have seen, are kept with most exemplary neatness, certainly not excelled in my observation. "The fore part of the winter," Mr Blake says, "the cattle are fed with cut feed (Green's straw cutter is used,) of meadow hay, barley-straw, husks, allowing each cow half a bushel of ruta baga per day. Since the cows have calved they are allowed two parts of English hay and one of meadow hay or barley-straw, with one peck of carrots twice a day to each cow. They are kept clean and fed with regularity."

The milk is placed in tin pails, the pails put in a caldron of boiling water and allowed to stand until scalding hot, and then put in pans to cool and remain until the cream is taken off. At the time of churning, a pint of heated milk is put into one pail of cream. The cream is not allowed to come near the fire, as it has a tendency to make the butter oily and of a light color. The time occupied in churning never exceeds half an hour. The butter is taken into a marble tray; the buttermilk all pressed out with the hand; the salt rolled to a fine powder and thoroughly blended with the butter.

Mr Denny adds in a note; "Three years ago I procured a marble butter tray with a hole through the centre, that the buttermilk might escape as expressed from the butter. The object was, that the butter might be worked in warm weather without ice; and presuming that it would be sweeter than wood during warm weather."

The sample of butter which I presented at the last meeting, was made when the cows were fed on carrots. The sample which I send to-day was made when the cows were fed one week upon beets instead of carrots. Mr Denny adds: "The color of the butter is changed, and I think the quality also. I have always leaned on the side of carrots; and on the whole am of the opinion that for neat stock they are the best and most profitable. Perhaps," he adds, "you will observe that the butter has more of a putty appearance when cut than that made from carrots. I have no doubt that beets will produce more milk than carrots, but inferior in quality."

I am of opinion that the trustees will consider this sample of butter as of superior quality, especially for winter butter. The trustees will understand that Mr Denny had no view to present this matter to the Board; and has given this account at my request. The butter seemed to me to be of such remarkable excellence for winter butter, that I knew the exhibition of it would gratify the trustees; and especially as showing, that with proper feeding of the cows and neat and skillful dairy management, almost as good butter may be sent to our market in winter as in June; and this deserves encouragement.

Should the trustees be of opinion that Mrs Blake's neatness and skill, as well as her husband's good management of his cows, deserve their commendation, an honorable notice of them, if it were only the expression of their favorable judgment in the case would, I am persuaded, conduce to farther enterprise and improvement in this matter of simple and innocent luxury.

I am, sir, with the highest respect,

Your obt' serv't,

HENRY COLMAN,

Commissioner of Agricultural Survey.

At a meeting of the Board of Trustees of the Massachusetts Society for Promoting Agriculture, held March 21, 1840, Mr Colman, the Commissioner of Agriculture for the Commonwealth of Massachusetts, having presented some butter of great freshness and excellence from the dairy of Mrs Blake, on the farm of Mr George Denny, at Westboro'—

It was voted, that the Treasurer be authorized to purchase and transmit to Mrs Blake, as a premium for her skill and success, a cream-pot or any other article of silver of the value of twelve dollars, and that the communication of the Commissioner be published.

A copy of the record.

(Signed)

BENJAMIN GUILD,

Boston, 6th April, 1840

Recording Sec'y.

The Commissioner had great pleasure in receiving and transmitting the above well deserved premium to Mrs Harriet F. Blake, of Westboro', on Saturday last.

NOTE.—In the notice of the very superior potatoes presented at the tenth agricultural meeting, as having been raised from the seed of the Chenango, by Mr Pollard, of Maine, it was, by an inadvertence, omitted to be mentioned that they were received by the Commissioner through the politeness of the Messrs Hovey, of Boston, who have some of them remaining at their store in Merchants' Row. They have proved excellent on being boiled. H. C.

BRIGHTON MARKET.—Monday, April 6, 1840.

Reported for the New England Farmer.

At Market 300 Beef Cattle, 25 yoke Working Oxen, 20 Cows and Calves, 310 Sheep and 1570 Swine. 40 Beef Cattle unsold.

Prices.—Beef Cattle.—We quote to correspond with last week; about the same prices were obtained, viz. a few extra brought \$7 00 First quality, \$6 50 a \$6 75. Second quality, \$6 00 a \$6 25. Third quality, \$5 50 a \$6 00.

Working Oxen.—Sales \$5 55, \$9 2, \$100, \$110, \$115. **Cows and Calves.**—Sales \$24, \$27, \$31, \$35, \$42.

JOSEPH BRECK & CO.

SINA SILK WORMS EGGS.

The Eggs of the celebrated Sina Silk Worm, now offered for sale, were raised in 1839, in M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The Sina Silk Worm was introduced to France from China by Louis XVI. in 1754, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France. Each sheet contains an ounce and is signed "Camille Beauvais." Price \$5.

WILLIAM KENRICK, Newton.

Or apply to JOSEPH BRECK & CO. Cambridgeport.

FOR SALE OR TO LET.

A wooden two story house, with six acres of fertile land, situated in Melford, within half a mile of the village. Said house contains four rooms on the first floor and six chambers. The premises are plentifully supplied, with a variety of choice fruit trees, in a thrifty and bearing condition.

A portion of the land is a superior location for a shipyard. The above is a pleasant and desirable place for a country residence.

For terms inquire of JONATHAN BROOKS, near the premises, or WILLIAM BRIGHAM, No. 33 Court Street, Boston.

March 25.

FOR SALE OR EXCHANGE.

A valuable farm in Harvard County of Worcester, the well known Bromfield Place, an excellent dairy farm, well wooded, the house spacious, fitted for two distinct families. The situation among the most pleasant to be found, especially for private or High School. Bordering a part of the farm is a beautiful sheet of water, containing two islands belonging to the estate. Inquire of the Subscriber at South Natick.

March 4, 1840.

H. T. BLANCHARD.

FRUIT TREES FOR SALE.

A good collection of Apple, Pear, Plum, Cherry and Peach Trees, for sale at the Pomological Garden, Salem, Mass.

Salem, March 18, 1840.

ROBERT MANNING.

Green House Plants.

Green House Plants of every description furnished at short notice, and well boxed, so that they may be sent to any part of the country in safety.

March 11.

JOSEPH BRECK & CO

1000 lb of the genuine White Silesia Sugar Beet Seed; the best variety for the production of Beet Sugar and warranted to be pure from mixture.

For sale by JOSEPH BRECK & CO. No. 52 North Market Street. Boston, March 4, 1840.

ROBAN POTATOES

A few barrels of genuine Roban Potatoes may be had on application to the subscriber. Price \$5 per barrel.

WILLIAM KENRICK.

Nonantum Hill, Newton, February 19.

GARDEN MATS.

For sale at the New England Farmer, 100 dozen Garden Mats, of extra quality, for covering hot beds, &c. Feb. 12.

JOSEPH BRECK & CO.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

He keeps constantly on hand a supply of Ground Bone, and solicits the patronage of the agricultural community. Price at the Mill 32 cents per bushel; put up in casks as delivered at any part of the city at 37 1/2 cents per bushel, and no charge for casks or carting.

Also, Oyster Shell Lime, price 10 cents per bushel at the kiln; put up in casks four bushels each at 60 cents per cask delivered at any part of the city.

Orders left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

March 4, 1840.

NATHAN WARD.

New York Urate and Poudrette Company.
JOSEPH BRECK & CO. are agents to receive subscription for stock in "The New York Urate and Poudrette Company."

The manures are not divided among the Stockholders, as are those belonging to another establishment, but sold, to applicants, for cash on delivery. Orders are supplied in the order of time in which they are received. Urate 50 cents and Poudrette 40 cents per bushel, with contingent charges for bags or barrels &c.

The material is disinfected and rendered free from offensive smell, by a compound, every part of which is in itself a good manure.

The experience of the past and present years, 1838 and 1839, on Long Island, has satisfied many of the farmers that these manures have the quickest operation upon vegetable matter, producing greater abundance, and the cheapest of any manure they have ever tried.

Amended instructions for their use, the result of practical experience, will be furnished on application. The effect of Poudrette upon Grape Vines and Morus Multicaulis is beyond all comparison. JOSEPH BRECK & CO. Agents.

March 11.

FLOWER SEEDS—CHOICE VARIETIES.

JOSEPH BRECK & CO. have received a choice assortment of Flower Seeds from England and France, which, in addition to what have been raised under their own inspection, embraces the finest collection to be found in the country, including all the new Annuals, Biennials, and Perennials worthy of cultivation; neatly done up in papers at 6 1/4, 12 1/2, and 25 cents each. For sale at 51 and 52 North Market Street.

February 5.

SILK WORMS EGGS.

Just received, a few ounces of Silk Worms Eggs, from Smyrna, said to be of a superior variety. Price \$8 per ounce, clean seed.

April 1.

JOSEPH BRECK & CO.

ROBAN POTATOES.

For sale at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at \$3 per barrel. October 16.

JOSEPH BRECK & CO.

BOX FOR EDGINGS.

JOSEPH BRECK & CO. have for sale 500 yards of Box for edgings, in prime order; price 37 1/2 cents per yard; every yard will make two when reset.

[NO. 41.]

N. E. FARMER.

For the New England Farmer.

LETTER FROM WILLIAM FOSTER, Esq.

Boston, 21st Feb, 1840.

MR COLMAN—Sir—Since you are of the opinion that some of my hints may be acceptable to the agricultural community, and being aware that my hasty remarks last evening, could not do justice to the various topics which I then merely broached, I will now offer you a few letters on some of those topics, in which I shall endeavor to give my recollections and thoughts in a more intelligible form.

If any speculative philosophers should be radical in their researches, it should be the agriculturists; or their speculations are so apt to be reduced to practice, and their consequences felt, for good or evil, that it behoves them, especially, to approach so near as it is allowed to man to do, the primitive cause of every desired or known effect.

Vegetation is now a mystery, and will probably remain such; but that is no necessary barrier to the boldest philosophical approaches to its cause and means, which the ingenuity of man can devise.

Now if time were so precious as to make it necessary to cut short these disquisitions, it might be thought inexpedient to go so far back as I am about to do;—but time is a cheap article with us.

When this globe, as the igneous geologists seem to think, was a ball of liquid fire, there could have been no water on its surface; and where the water came from we know not: here it is, and it seems to be the great menstruum of vegetable and animal life, as well as one of the principal agents of mineral composition. It is equally necessary to the formation and decomposition of all nature's works.

When the water first made its appearance on the surface of this globe, after it had sufficiently cooled to bear it in a liquid state, it found, surely, no alluvial bottoms, no rich intervals fraught with vegetable matter. All must then have been dry volcanic scoria, or igneous mineral;—no secondary or tertiary formations. At this period—if I may be allowed to suppose such an one; and I may as well suppose it, as to take for my purpose a mountain range of barren granite rock,—at this period, I say, we find ourselves reduced to the comparatively simple elements of air, water, heat, and caput mortuum. Vegetable and animal existences are not yet produced. Nature now opens her mysterious bosom, with powers and means unknown to us. The heat which we can produce, compared with that of her chemical furnace, is like polar ice; and her hydrostatic press is as much superior to all imaginable human power, as the pressure of an inverted pyramid of Egypt resting on its apex, would be to feather pressing the same surface.

Water, air and sun, great agents in the hands of the Creator, now begin the work of vegetable formation, either out of their own substance or with that substance combined with the hard crust of the earth; which last has never been supposed to pos-

sess any generative powers, but only the powers of cohesion and attraction. Experience, however, leads us to suppose that this hard and barren crust is operated upon chemically and mechanically by the other three active elements: chemically, through various combinations, unknown to human chemists, or even to Albertus Magnus, the great alchemist of old, whose powers were supposed by the vulgar to be not altogether human;—and mechanically, by contraction and expansion, occasioned by changes of temperature. Now we are acquainted with some of the chemical powers of air, water, heat and light, separately and combined; and it is not difficult to imagine such others as would decompose and render a fit aliment for vegetable composition the hardest substances, even flint. Glass we know is decomposed by exposure to the atmosphere; and why should not silex, or sand, which enters into the vegetable compound, be thus prepared, or even rocks of every description? That the rocks have been very much diminished in the greater part of Europe, must be evident to those who have seen much of that part of the world and compared it with America.

Those feeble beginnings, which seem to be the first rude essays of vegetable life, observable on the barren rocks, and called Lichen, by annual decay and reproduction, being washed down by the rain to a stable resting place, would in time afford aliment to vegetation of a higher order; as in the animal kingdom, the *small fry* is pasture for larger animals. The metals, we know, are reduced by acids from their most compact and adhesive form. They are also decomposed by the active elements of nature, and made a suitable pabulum for vegetables where we find them incorporated.

I have dwelt thus long on a known process of nature, too familiar to every one perhaps, to require so much notice, and for the purpose only of fixing attention to the various means of drawing from the prolific earth her hidden treasures. The production, decay and reproduction of vegetable and animal matter in its organized form, pound for pound, or a proportionate yield of these products, for a given quantity of old vegetable or animal material; or with that increase derivable from the forest, the ocean, the bogs, or other sources of prepared aliment, should not be the limit which enlightened philosophy should admit; for that would be making no allowance for the increase of our race beyond the territorial limits of our country—which country may be before many years, perhaps, a single State. Moreover, the forest, the ocean, and other sources of an increased supply of vegetable aliment, may not be within the reach of many, and yet the want of an increasing supply of products be sensibly felt. These sources of increase are too well known to be neglected for any speculative essays on the decomposition of rocks or sand. But, when their present value is known, and the importance of preserving and economising them is attended to, we may safely venture to speculate on the very probable agency which these things themselves have, in reducing the stubborn rocks and the fleeting sands to vegetable nourishment, and spreading wide their

nets to draw from the air, the rain and the light, the vivifying principles of vegetable life.

It may be useful to dwell somewhat more, on the less obvious sources of vegetable formation, without derogating from those more obvious sources, such as manure, with moisture and heat; for vegetation surely began without manure, since it probably preceded animal life.

Rocks and sands may be partially decomposed by the gentle dews and small changes of temperature of Arabia Petreae and Egypt; but the barren condition of those countries, where a few secluded spots alone show any signs of vegetable life, proves that *more water*—nature's prolific handmaid—is required to cover those unlovely regions with a new coat of verdure.

I will now leave speculative philosophy to those who may incline to apply it further to the purposes which I have had in view, but merely to illustrate, and to fortify the theory of close cultivation and shelter, and the preservation of forest trees on all lands fit for no other use, and especially on high lands. I would even recommend frequent green borders of forest or fruit trees on the best arable lands, and artificial borders, if they can be raised, on our vast prairies of the West.

Fortunately, there are numerous historical facts to corroborate the theory above. When the Phoenicians, with a view to extend their commerce, reached the columns of Hercules, they found there that beautiful country now called Spain, which they then considered the end of the world. The principal attraction for these merchants was the rich silver mines of that new country; and they speak of its implements of husbandry being of silver, and of having ballasted some of their ships with that metal. But they tell us what is more to our purpose; that the country was exceedingly fertile, well watered and wooded. We learn from the Roman historians, at a later period, that Spain contained a population of fifty millions. Still later, in the reign of Ferdinand and Isabella, it contained twenty-two millions of inhabitants. And now it barely supports a half-famished population of about ten millions. Yet this favored spot of the earth has the best climate, a good soil, and is almost surrounded by the ocean.—In my youth I spent several years in Spain; and in travelling over the country, I was surprised to find it so divested of wood, where little else could be expected to grow, viz. the hills and mountains. The number of dried rivers (*rio secos*, as they are called,) was equally remarkable. As Spain has now very few good roads, these dry rivers are commonly used as the best mule paths for travellers; and it is not uncommon to see the remains of fastenings in the rocks, where the boats which navigated those rivers made fast. Immense tracts of arable land once highly cultivated, are now to be seen with scarce a spire of vegetation upon them. Even weeds require the shelter of more lofty vegetables and their aid in the attraction of moisture. Thus has that once fertile and populous country, lost its vegetable and animal products.

Now is there any thing unreasonable in attributing this astonishing change to the destruction of

the forests on the highlands, their attraction of water from the atmosphere to irrigate the sloping hills and the valleys, and to replenish the rivers, and to cause them to fertilize the bottom lands with their annual inundations? The evidences of ponds and lakes are discernible every where.

This now fortunate country which we possess, is in the full enjoyment of advantages lost to the unhappy Spain. Shall we secure them by a prudent use, under the guidance of an enlightened philosophy, or shall we, like the prodigal son, dissipate and waste this goodly heritage? Shall we kill the hen which lays the golden eggs? Shall we strip our highlands of their trees, which bring to all that lies beneath, the essential part of our golden harvests?

The Gauls, generally, when first conquered by the Romans, were well wooded; and those parts of the same country, now called western Europe, which have preserved the most forests or found a substitute in the cultivation of ornamental trees, or the vine and the olive, remain the most fertile; and the best vintages, and the best crops of all sorts, are made under their shelter.

Perhaps it may conduce to the object now in view, viz. the preservation of forest trees, to state the difficulties of replenishing with wood the hills or vast open tracts of land exposed to the storms of winter or the desiccating blasts of summer.

Between Bordeaux and Bayonne, in France, there is a great extent of sea-coast, from whence are blown immense drifts of sand, which were encroaching fearfully on the fertile soil beyond. The French government had made various attempts to stop its progress, until about seventy years ago, when a philosophical engineer proposed to prepare a wide belt of land, the whole length, taken from that part yet capable of cultivation, and to sow it broadcast with pine. The plan succeeded, and the sand-drift has been stopped. The sectional view of this plantation explains the whole philosophy of the scheme, in the most graphic language. The trees nearest to the shore are very short, and almost buried in sand; but the successive lines inwards, rise gradually, until the innermost range presents full grown trees. This may be a lesson for some of our western farmers, if they should ever find it necessary or useful to protect the grain and the grass of the prairie lands from the exhausting blasts of summer or the chilling winds of spring.

Now to replenish the denuded hills with their coat of verdure, is a more difficult task, and requires ages to accomplish it. This has not yet been effected, I believe, by the hands of man; although it was attempted many years ago by the government of Spain. Colonies were brought from Germany with a view to improve the cultivation generally, of the neglected soil; they were located in the hilly country. It seems that the colonists were aware of the importance of covering the highlands with those fructifying forests which they left at home; and made various attempts to effect this, but all, thus far, unsuccessful. In fact, they began wrong; they wanted the aid of the French philosophical engineer; they began on the highest ground, instead of beginning at the foot of the hills. This last was probably nature's process, when she first began to clothe with verdure the hills which her internal fires had thrown up. But it will be perceived here, that the broadcast plantation mentioned above, which was but an affair of sixty or seventy years, would require many repetitions of that period of time, to climb to the top of high hills

by the same process; for the ascending forest could climb no faster than that it could find shelter from below.

These, then, are the difficulties of clothing hills which have been once thoroughly deprived of their trees, in an open country, without adjoining forests; and that consideration ought to make us think twice before we cut down a single mountain tree. Although such forests were never to know the axe, still they would pay good interest to the whole neighborhood; and it might be good policy for townships to own such highlands, and to keep them untouched forever. Much timber was imprudently cut down in Spain to build ships, and to furnish outfit for the golden harvest of South America, whose discovery was the most unfortunate event in the history of Spain.

The attraction and the discharge of the clouds in rain and electric fluids, by forest trees on high lands, is not the only advantage which may come from that source, if there be any truth in the conjectures above, on the formation of vegetable aliment. If that theory be correct, and I can discover no reason to doubt it, these wood-capt hills must be perpetual laboratories of vegetable substance, which every shower brings down to the plains below. It is like the fertilizing waters of the Nile, which bring from the mountains of Central Africa their superfluous vegetable matter, without ever exhausting the supply.

I would offer a few more remarks, to convince the most incredulous, if any such there be, that vegetable matter may be greatly increased without the aid of manure, and by the combined action of the elements, among which water seems to be the material basis, and heat, air and light, the vivifying principle—the *effluvia* of vegetable life.

(To be continued.)

For the New England Farmer.

LETTER FROM JOSHUA K. LAWTON,

Explaining his Mode of Cultivation.

GT. BARRINGTON, March 20th, 1840.

Rev. H. Culman—Dear Sir—I cannot do justice to my feelings without tendering to you my unfeigned thanks for your repeated favors, and especially your personal visits at my place. The honor conferred on me by the Massachusetts Agricultural Society's committee, in making me again one of the successful competitors on farms, is of no small gratification; therefore I do feel much indebted to you, sir, for your arduous labors in carrying into operation this great and grand stimulant, which has caused the breast of the husbandman to thirst for knowledge and instruction, awakening into action and directing the dormant faculties of men to their best interest, and that too which enlarges and fills their barns, multiplies their bushels of grain, and renders their soil healthy and productive.

In viewing the report of the committee, I find their views do not all correspond with my theory of ploughing sward land and stacking hay. In those particulars I will give my reasons why I differ in practice from the opinion of the committee.

Ist. I have been a dependant farmer, standing in need of the avails of my fields for defraying the necessary expenses of the farm and family; therefore it has caused me to experiment (though not extensively,) more or less every year, and especially in ploughing, and that too in the commencement of my farming system. Deep ploughing, where the

soil is thin, either naturally or made so by shallow ploughing and tillage, calls for 40 or 50 cords of manure to the acre, to prepare it to bring a good crop of corn. If a dry season ensues, and the manure is not incorporated with the soil, the plant suffers for the want of moisture, and the crop is light. The farmer in the country where his means are limited for making or procuring manure by purchase, can do justice to but a few acres; and therefore cannot raise one quarter of the grain or roots necessary for fattening their swine and beef cattle, and for family consumption. Of course he cannot meet the demands that will come against him, and consequently he must fall in arrears. Should I have one or two hundred acres of this tillable land, much of it must lie a number of years in dormant, useless state, before he can, by ploughing and manuring, bring it into a state of fertility, which would require surplus funds to some considerable amount to carry on his business. "Necessity, with me, has been to some extent, "the mother of invention." This plan, therefore, I have adopted, and as rigidly as I have been able, have pursued the method of ploughing which I have stated in my communication to the committee of the Massachusetts Society on farms; that is, to make all the manure I can, plough deeper and deeper every year, accordingly as I can manure, and bring my land in a steady progression up to a high state of cultivation. I would explain myself more fully by giving you a statement of the management of one lot of twelve acres, which had been ploughed shallow, being rather cold clayey land, as much so as another I have.

The first years after it came into my possession it was almost useless to me. It had no sward and yielded no production of much value. The sight of this lot gave me pain every time I crossed it, though my neighbors would sometimes say to me they had seen good crops on this ground for some years after it was cleared off. In the year 1837, I made up my mind to see what I could do with this dormant piece of land; I therefore stacked upon it some hay, peas and straw; foddered their out of the land, drew on and spread twelve cords of manure to the acre, mostly compost, and in the spring of 1838, I ploughed it carefully to the depth of five inches, which brought up some yellowish dead loam. I then harrowed and planted it to corn about the 10th and 12th of May. It came up appearing rather sickly, being on this dead loam. I then had it plastered and hoed; and until the roots had reached the manure, it wore the same forbidding appearance that the lot had shown for years past. It was ploughed and hoed three times. It finally returned me fifty-eight bushels and some quarts to the acre. In the following spring of 1839, I sowed it to spring wheat and oats, after ploughing six inches deep, which was an inch deeper than it was ploughed in sward. It gave me twenty bushel wheat and fifty-five bushels oats to the acre. For the wheat on this land, the committee of the Berkshire Agricultural Society gave me the first premium.

Thus you see, sir, that the system which I have pursued for many years, cannot be the *worst* if it is not the best. I however hold myself open to conviction on this as well as on every other branch of my profession.

About 14 [loads?] of manure were all that could be spared for this lot. Had I put this manure on three acres and then ploughed it eight or nine inches deep, it would have taken the corn roots all

summer to have reached the manure, and my crop would not have been probably one-half what it was. "Circumstances alter cases." A man having manure sufficient for his land and incorporating it with the soil after ploughing deep, suffering the inverted sod to remain, is best in my opinion, and will be so considered by every practical farmer.—My motto is, *Outward*—and I find in operating, there is more to be results; and from these I find myself under the tuition of that excellent schoolmaster, experience.

A few words will suffice in respect to stacking hay. I have the last year made an addition of a considerable extent to my barns, by building, and ten was under the necessity of making nine hay-racks of four tons or more in each, having my barns, cow-house, and straw-house all as full as they could be stowed. I am of the opinion of the committee of their being a loss in hay stacked out, and also that stock suffers much by not having a shelter. But this is not my plan; my stock is all sheltered, or have the means of shelter either at barns or shanties. My intention is to build another barn as soon as I consistently can.

JOSHUA K. LAWTON.

ON STAKING NEWLY SET TREES.

We give the subjoined communication without any knowledge whatever of the person or paper referred to; having never seen the directions for supporting newly set trees, to which the writer refers, and having never heard of them before. If any other answer is received, it shall certainly have a place; but should it unfortunately lead to a challenge, (for editors are a very combustible sort of animal,) we give it to be distinctly understood that we are no parties in the case, and shall carry no votes and not even prime the pistol nor hold the cogne bottle. As to the precession caps, after arising of the dreadful accident of the child that allowed half a dozen of them and then exploded on drinking a tumbler of cold water, into (as one of our female acquaintances says) a million of atoms! we should hardly venture to come within sight of one.

H. C.

For the N. E. Farmer.

MR EDITOR—Some years ago I had some little experience in transplanting trees, and knew something about that business, or—*thought I did*; which now, I believe, pretty generally admitted to be the same and the same thing. I have not yet forgotten it all, and feel desirous of giving to the lover of antiques, what little there is left, before I forget it. I do not select your paper because it is the best, but only because it is older than some others. I distinctly remember that in regard to "staking;" something like the following wandered in my mind.

The broken roots, like a broken bone, when set in, require to be kept still. The little particles of nutritious matter in the earth, obedient to the laws of their Creator, set themselves in motion to enter the roots, to heal their wounds and increase their size. These little things, as seems very reasonable, desire to know where the root is to be found. The least distance is to them more than mile is to us. If the root is kept perfectly still, great numbers of them will find it in a short time—perhaps the first day. But if it be frequently mov-

ed, the least conceivable distance, they will never find it at all, and the tree will not grow.

To prevent this evil by keeping the roots still, I used to have a way of "staking up," which I thought a good one enough, and it seemed to answer the purpose. But a native modesty, which I could never get entirely rid of, prevents me from stating it till after giving another method from a better and higher source.

The editor of a certain paper, whose name, in tenderness to his modesty, will not be made public, has given us the method in his last paper. It was not entirely new to me, inasmuch as it had been imperfectly shadowed forth in preceding numbers of the same paper. But it is justice to the editor to say that, so far as my limited researches have extended, the method is believed to be original with him.

Well, as I was saying, in answer to an inquiry from one of his numerous, laudatory, and confiding correspondents, (which some, with a sneer bordering upon impudence, have wickedly intimated are manufactured to order,) our editor gives his method in the following language:

"When the tree is carefully set, stake it up with a lot of old straw, poor hay, sea weed, or litter from the barn-yard. Let this be pressed down close about the body of the tree, and no further support will be needed for one that is of decent size.

"A little racking by the winds will not prove injurious, when there is litter about the body, so that the air will not get in to dry up the roots."

It is true that I have not given this method the deliberate meditation and study which its intrinsic merits doubtless deserve. And it is unquestionably for that reason, that I am not able very clearly to discern how the roots are to be kept still, if the wind should happen to be stronger than the straw; and I cannot get rid of the old exploded maxim, that "I staves show which way the wind blows!"—nor can I see what is to keep the boys and other unmanageables, away from the trees. But I will be candid, and confess that, if by a "decent size," is meant a tree so small as to be beyond the reach of the wind and the boys, the main difficulties are removed.

It is not probable that the old-fashioned way of "staking up," which I adopted, *de bonis non*, (to speak in English) for the want of a better, can, in this age of enlightened improvement, be of much interest to any one; but I have promised to give it, and it must therefore be done.

Take three genuine, bona fide stakes, and set them round the tree at about equal distances from each other, and eight inches or more from the tree. It is best to set them when the tree is set; as they may thus be made to stand firm, without any danger of interfering with the roots. Their size and length must of course be proportionate to the height of the tree. Take three strips of leather, or strong cloth, an inch or more in width, and pass them round the tree, nailing both ends of each to a stake. The straps should be up as near the limbs as convenient. Before putting them on, tie some rags or hay about the body of the tree, to prevent them from chafing the bark—taking care to tie it so loosely as to admit the air to pass through. Two stakes will do, but three are better. The body of the tree will thus be kept still, and consequently the roots. The incipient process of their growth cannot be interrupted. They will very soon feel at home, and the growth of the tree will be but little retarded by its change of place.

If the body of the tree be crooked, it may be made to grow straight by putting the straps in the proper places.

The two methods seem, it is true, to be different; but not more so than is to be expected in this age of improvement; and I submit it to a candid public to say if they do not resemble each other as much as a sub-treasury and a national bank.

Yours,

L. H.

ON THE CURCULIO.

Plymouth, March 18th, 1840.

To the Editor of the New England Farmer:

DEAR SIR—I have been gratified by the perusal of Dr Burnett's communication in the Farmer of the 11th inst., on the subject of the Curculio. There are few insects more destructive to our cultivated fruit than the various species of Curculio; and it has long been my desire to see among fruit cultivators a union of efforts for its entire extermination. That the extermination of this pestiferous race is in our power, I have no doubt. But however valuable the experience and observations of Dr Burnett, according to my experience something more is necessary to render the remedies infallible. It is well understood that it is by the mode of propagation that this insect effects the destruction of our fruit. The female parent is led by unerring instinct to deposit her eggs where the grubs or worms will be supplied with nutriment as soon as required: it continues however, but a short time to receive its supply from the plum or apple in which it is embedded, and a continuance of existence depends on its finding and entering the earth, where in its chrysalis state, it remains during the ensuing winter. A part of this progeny find a vehicle of conveyance to the earth in the immature fruit, containing them, falling to the ground; but a considerable portion are known to anticipate their future destiny by means of a web of their own forming, by which they web themselves down, leaving the fruit in its ruined state on the tree. Thus they elude our vigilance and cheat us of our finest fruits. We should now use our best endeavors to intercept their progress into the earth. In the first place, let all wormy fruit as soon as discovered, be immediately destroyed, and not suffered to be one hour on the ground for the worm to escape. Next, there are many materials which if spread under the tree to the extent of its branches, will effectually prevent the descent of the grub into the earth: these are lime, wood ashes, fresh sea-weed, ground bark from tan-pits, coal ashes, &c. These substances, except the two last, are very beneficial to the soil. In the spring the same materials must be employed to prevent the ascent of the female beetle to deposit her eggs on the tree.

This course if adopted in addition to the judicious measures recommended by Dr Burnett, we may be assured will in a few years exterminate not only the curculio, but the canker-worm, and many other noxious insects. It is possible that the curculio may fly over a fence from a neighbor's garden, but if all the cultivators will unite in the measures recommended, no mischief need be apprehended from that source. Let us then be vigilant in our warfare.

Not many years since an old English pear tree came into my possession: it had for several years been so greatly infested by the curculio, that one-half of the fruit fell to the ground in a wormy, immature state. For four years last past, I destroyed

every wormy pear that fell from the tree: this has effected a very essential improvement in the condition of the fruit. I collected some of the worms taken from these pears and put them into a box of earth in the collar: they lived through the winter a few inches below the surface, but in the spring they either died or made their escape: the experiment is worth repeating.

There is another process to be recommended, in which I have great confidence, as a part of our warfare against the curculio. It is, to make a direct attack upon the female beetle while she is about to puncture the fruit to engender her young brood. This may be done by throwing from a garden engine or Willis' excellent syringe, a liquid substance that will create a sort of deleterious atmosphere which will compel her to quit the tree, and will destroy the vitality of her eggs, should they have been deposited. I will name the following articles for this purpose:—the composition of sulphur and lime recommended for grapes in Mr Kenrick's Orchardist, page 328; a strong decoction of tobacco or snuff; chloride of lime; a weak solution of potash or even soap-suds. These materials, if showered over the trees and fruit, would prove so offensive as to force the female visitor from her generating process. The most proper time for this operation is in the evening, in order to meet the enemy, whose attack is supposed to be during the course of the night. This operation should be repeated several times during the week, from May to August, and the tree should frequently receive a thorough shaking, by which the insects will be greatly disturbed and made to fall to the ground. Should my plan be deemed too onerous, the cultivator who may adopt it in full or even partially, may be assured that (in my opinion) he will have no cause to regret his labor.

Respectfully, yours,

JAMES THACHER.

P. S.—In the Farmer of Oct. 2d, 1833, I communicated a sure method by which bees may be secured against the depredations of the bee moth. It should arrest the attention of bee cultivators at the present season.

For the N. E. Farmer.

ON ASHES AS A REMEDY AGAINST THE TURNIP FLY.

New York, March 28, 1840.

MR HENRY COLMAN.—Dear Sir—Referring you to "W. B." in the N. E. Farmer of March 16th, respecting the Black Fly, I will suggest the common and effectual remedy as far as my experience has gone, viz.: sow ashes (dry) broadcast, a peck or half bushel to an acre, when there is moisture or dew on plant, whether turnip, radish, melon, cucumber or any other article that the fly may attack: the best time is the second or third day from the time they make their appearance—the sooner the better after they are out of the ground; but as they will not all appear at once, it is as well to wait a day or two; but if the farmer happens to wait six days, he will not find a single turnip in a field of acres, and will insist that the seed was bad. I have known seed to fail with some and prove good with others, when this was the only seed.—This specific I will call it, though commonly known among farmers, may not be known to all; therefore before the season of sowing turnips each year, I think it should be published in every agricultural

periodical in the country. Some farmers sow ashes upon their turnips (and have good success thereby) because their fathers did so before them, without knowing the reason why or wherefore.

Allow me to recommend to my brother farmers, whom I may be allowed to call so, though pent up in this great city for the present, (but for the present only,) to ask a reason for every thing that comes under their observation, and we should go ahead in agricultural improvement faster than we ever have done. Opinions are worth nothing without the reasons, to my mind. In my religion, my politics, and my profession, I must have reasons: opinions are useless lumber to me without.

By a recent notice of the 'borer' of the locust, I observe that it does not like shade or smooth bark. *Hint.*—May it not lay its eggs in the rough bark, and may not the sun be necessary to hatch them? Would not scraping the bark be beneficial, and some artificial shade answer as well as large forest trees?

I presume all that is necessary to obtain a remedy is, to study the habits of the animal, and by concentrating the information of all observers in the agricultural papers, we shall soon be able to find out the ways of the animal, and as I have quite a large number of young locusts to cultivate, shall feel under great obligation for information, and shall not fail to give any facts that I can obtain.

Respectfully, yours,

J. G.

For the N. E. Farmer.

LIME—RUFFIN ON CALCAREOUS MANURES.

MR COLMAN.—Sir—I have perused with very great interest your weekly reports of the agricultural meetings during the session of the legislature; and as most of the gentlemen that have spoken upon the subject of agriculture are practical farmers, their experience is of great value to the farming interest generally. They pursue some different courses, and have different views in the cultivation of their corn and other crops, but upon the whole it will have a good effect, and excite to inquiry and investigation many farmers, and stimulate them to step aside from the old beaten track they and their fathers have pursued, and imitate the courses pointed out at your meetings.

Upon the use of lime, there seems to be much difference of opinion. In my own vicinity, within four years past, there has been much money expended in the purchase of lime for agricultural purposes, at from \$2 50 to \$3 per cask for Thomaston lime: it has been applied in various ways, and as far as my knowledge extends, no one can tell whether he has derived any advantage from it or not. They have not been careful to make and note experiments, but in true Yankee style, guess it is good as a manure. Some farmers have applied it to their growing wheat, and have raised good crops, which was mostly attributed to the lime: others have grown equally as large without it. Dr Jackson, I believe, thinks it of great importance in agriculture. Dr Dana says, "a bushel of ashes is equal to a cask of lime." B. V. French, Esq., in his remarks upon the cultivation of wheat, at the eighth agricultural meeting, stated that he used 150 bushels lime per acre; his own experience was unfavorable to it, and some others had not derived much if any advantage from its use.

So also the Berkshire marls have not proved so beneficial as was anticipated, from the great amount of carbonate of lime they contain.

I have lately had the perusal of a work on the calcareous manures of Virginia, by E. Ruffin, Esq., who after many years' experience, and with the most careful, accurate and numerous experiments, has proved, I think beyond all question, their great value in agriculture; and as the shell marls of Virginia, the Berkshire marls and the lime from the State of Maine, are almost the same thing, that is, the carbonate of lime, I can conceive of no possible reason why lime and marl may not be as useful and as profitably employed in Massachusetts as in Europe or Virginia or New Jersey. But I think every farmer who purposes to use lime or marl, should procure Ruffin's Essay on Calcareous Manures, and carefully peruse and study the work, which will enable him to apply his labor and means more understandingly. There is, without doubt, many soils upon which lime would be of but little or no use, but if there is any reliance to be placed upon chemistry, it must be of much use upon soils containing oxide of iron and sulphur, as the lime will combine with the sulphate of the iron, and form the sulphate of lime, or gypsum. It may be equally useful upon acid soils, or such as grow sorrel and pine luxuriantly.

B.

March 30th, 1840.

We shall venture no opinion in this place on the subject of lime, referred to in the above letter of our esteemed correspondent; but we perfectly accord with him in the estimation in which he holds Mr Ruffin's work on calcareous manures. It is an essay of much merit, showing great intelligence and carefulness of observation. Whatever conclusions on the subject of the work the intelligent reader may form, he cannot fail to entertain very high respect for the tact and talent of the author.—Mr Ruffin's book on calcareous manures and his Farmers' Register, published monthly, and edited with distinguished ability and knowledge, and eminent fairness of mind, ought to be possessed and read by every inquisitive farmer in the country.

H. C.

MASS. AGRICULTURAL SOCIETY.

Answers of Ichabod R. Jacobs to the Interrogatories of the Committee of the Society, as presented in their proposals.

- No. 1. My farm consists of one hundred acres.
- The soil is gravelly and rocky, loamy, and lowland or bog meadow.
- I think the best management to be this: to plant corn and sow rye at the last time of hoeing, and after reaping the rye, take another crop of corn, and then lay it to grass with oats or summer rye. I plough up some of the rocky land and plant with potatoes one year.
- I till and sow ten acres a year, and put about ten loads to the acre.
- My mode of applying my manure is, to apply a part manure and a part in compost.
- I spread and plough in one-half of my manure and put the other half in the hill.
- My mode of cultivating green sward is, to plough it in the summer or early in the fall, and again in the spring and harrow it.
- I mow sixteen acres of grass and obtain about a ton to the acre.

9. I have not practised irrigation.
10. I put on my English mowing as much horse manure as I can obtain from my stables; how much to the acre I cannot say; but I put it on where I think it most needed.
11. I mowed about ten acres of fresh meadow the present year, and obtained six tons of hay of rather a poor quality; also eleven acres of black-grass meadow, and obtained about fifteen tons of good hay.
12. I have not redeemed any meadow land.
13. I planted four acres of corn this year. I ploughed the land in the fall and spread part of the manure; ploughed it again in the spring and harrowed it: my seed was the common yellow corn. I put of compost manure about ten loads to the acre; a part of it in the hill. I had thirty bushels on an acre, and also about twenty cartloads of pumpkins on the same ground.
14. I planted one acre of potatoes: I planted in the hill; put on fifteen loads of manure and raised about a hundred and fifty bushels of long red potatoes and chlenangos; also thirty bushels of turnips on the same ground.
15. I cultivated also half an acre of beans, pease, squashes, cabbages, beets, carrots and French turnips, for the use of my family.
16. I sowed six acres of grain. The land was ploughed in the fall and spring and rolled: sowed one bushel of rye, or five pecks of wheat, or three bushels of oats to the acre. I cultivated a bald wheat in a loamy soil with the use of lime.
17. I have stocked down to grass the last year six acres: two in the fall and four in the spring. I am accustomed to sow half a bushel of berds grass, a bushel of red-top and five pounds of clover on an acre. It was sowed with grain.
18. For the purpose of making manure I get mud, loam, leaves and stuff out of the woods, and some straw to litter.
19. My stock consists of two oxen, four cows, nine young cattle, two horses and ten sheep. Of my barns, one is thirty by forty feet, the other thirty feet square. I have no cellar under them.—My manure is not covered.
20. My cows are of native stock.
21. I allow my calves to suck the cows until they are about three months old.
22. I make about two hundred and fifty pounds of butter and four hundred pounds of cheese: not all of new milk but all good.
23. I have nine swine. I keep three over winter and make a thousand weight of pork. They are of the common breed.
24. I feed my hogs on whey and meal and apples in the summer, and fatten them on potatoes and pumpkins boiled, and meal and corn.
25. Of compost manure I obtain twenty loads, made of trash and ditch sods from the meadow and some green stuff mowed, and some straw and some loam.
26. The labor of my farm is performed by myself, one man and two boys. I generally pay \$12 per month the year round.
27. I have 200 apple trees, some grafted and some natural fruit.
28. I have fifty peach, plum, pear and quince trees.
29. I have never been troubled either with canker worms or borers.
30. I have not drank a glass of spirit for forty years, and have not used any for my laborers for

several years. I think it is of no use: they can do more without it than with it.

ICHABOD R. JACOBS.

Suite, Nov. 29, 1839.

[The Committee of the Society awarded Mr Jacobs a gratuity of \$50.]

For the New England Farmer.

EVERY THING IN ITS PLACE.

But this cannot be practised unless a place be provided for every thing. When a man takes possession of a particular premises, he should make a general and then a particular survey of the various implements which are on hand and the conveniences afforded for the disposal of them. This done, he should determine upon the place which each article shall occupy; and if there are many persons in the family, some designation should be made, so that no mistake be made about it. When this is done, then he should himself be very particular not to transgress his own arrangement, and that others shall not do it. The axes, the shovels, the iron bar, hoes, rakes, baskets, wheelbarrow, each, every one, and all, should have its hook, nail, location, and when not in use, kept there. It may sometimes be thought unnecessary to be so particular. It may be supposed just as well to leave them where you expect to use them next; but before this *next time* comes, you may alter your plan, or some other of the family may have occasion for them and you at the moment be out of the way; or you may have forgotten; then comes the inquiry, the hunt, the general wonder where the article can be; then follow mutual suspicions that each other has been in the fault; next, recrimination; then evil surmises that some neighbor has without leave *borrowed* it, and neglected or forgotten to return it; and in the end, beside all the excitement, recrimination and evil surmising, twice the time and labor is lost in searching that would have been required to put the article in its place at first. I have presented no overdrawn representation here: all and more than all of the evils above numbered, I have known many times to have grown substantially out of what many would think hardly worth a notice. A hoe or some other utensil had been left where it was last used instead of being put in its proper place, and a whole family set in confusion thereby. How serious then must be the inconveniences, how many the excitements in those families where nothing has a place, or where if things have their places, the members are negligent about putting them there.

B.

CUCUMBERS AND MELONS.

Among the first and greatest difficulties in raising cucumber and other vines of a similar nature, is their liability to be destroyed by a worm under ground or the yellow fly above the ground, soon after they come up. I could not well count up the number and varieties of the preventives which I have used to guard against this evil, and sometimes with apparent success; but as a constant and effectual security they have all failed: neither elder blossoms, lime, soot, ashes, pepper, mustard, alkalies, nor acids have done the work effectually and lastingly. My method now is, to plant so many, say a hundred or more in a wide hill—no matter if the whole ground devoted for the vines to run upon be sowed entirely over with them. In this way there will be sufficient for the flies, and enough escape

uninjured. This I believe upon the whole is the safest and least troublesome method. The only plausible objection that presents itself to this course is, that in choice varieties great quantities of seed cannot be afforded; but the objection may be obviated by planting the choice seeds in the centre of the hill, and putting up such marks as certainly to designate them, and then planting common seed around them. Let those who have been disappointed in their former preventives, try this. I think they will upon trial approve it. If they do not, and can find a better, I hope they will communicate their discovery, as I do this, to the public, for the common good.

If any upon reading this, shall reject it upon the principle that it is 'book' gardening, such will permit me to say that I have communicated the same fact to many of my neighbors and friends, by *word of mouth*, and it has worked well with them, and I cannot believe that ink and paper will mar its operation.

B.

For the N. E. Farmer.

USEFUL HINTS.

On many farms there is mowing land which produces a good crop of after grass, or second crop, which is very good for milch cows. It is the practice of most farmers to turn their cows on to such land in the morning, when there is a great white frost, apparently not thinking that it is very detrimental to the grass.

If any one will drive cattle or a team on to a good growth of such grass, when the frost is on, and will take a view of the same grass in the afternoon, he will find it killed—looking as if fire had been on it.

Beside the injury to the grass, the cattle will not eat until the frost is off, but will keep travelling, to the great injury of the grass. Cattle ought not to be turned out of the yard and be permitted to go on to such grass till the frost is off. My cattle are never allowed to go on to a large crop of feed when the frost is on, but are kept confined in the yard until the frost is off.

Whenever cattle are put from a short pasture to a large growth of grass, they should not be allowed to remain on it at any one time, longer than suitably to fill themselves: this for two reasons;—one is, they will eat more than does them good, and perhaps injure them; the other is, they travel about or lie down; either of which is injurious to the grass.

A FARMER.

March 26, 1840.

Rotation of Crops in Gardening.—A rotation of crops should be observed in garden as well as field culture. As a general rule, tap-rooted crops should succeed those of spreading roots; those with large and luxuriant leaves should succeed those of less size; those requiring much tillage should be succeeded by those needing but little culture. Deficiency in practical and scientific information relative to the proper succession of crops, renders it advisable to sow red clover on alternate portions of the garden, even if it is ploughed or spaded in the same season. The sowing may be at the last hoeing of some crops.—*Rural Library.*

New potatoes were for sale in the Baltimore market three weeks since.

Strawberries at N. Orleans sell at 4s. a pint.

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, APRIL 15, 1840.

ON THE VALUE OF PUNCTUALITY.

Our friend's remarks below are delivered in a plain way, but are not on that account the less valuable. We commend them to the special attention of those who are setting out in life; and their bearing upon domestic peace and good will, is placed in a striking but not too serious a light. In all matters of business, indeed in any fixed appointment, the want of exactness and punctuality is inexcusable; and in many cases is entitled to no milder designation than that of an immorality. We will suppose an individual engages to meet a committee of ten or twenty at a fixed hour. Nineteen of them are at the place precisely at the time, but he does not make his appearance until a quarter of an hour after the time. This is a positive loss in the aggregate, of nineteen quarters, or four hours and three-quarters of time; and if these individuals have other fixed appointments, it is not easy to say how many persons may be put to great inconvenience and suffer very serious loss and much mortification by the neglect of this individual. Suppose an appointment is made with a tradesman or a laborer, or a professional man. His time is his money. Very great loss must be occasioned to him by unnecessary delay or disappointment. Robbing him of his time is not a whit more venial than robbing him of his money; to say nothing of the disappointment which it may compel him to occasion to other of his employers. What example can be more instructive or more useful than that of Washington, who was scrupulously precise in every engagement; who allowed ten minutes for a possible variation in clocks, but waited for no guest beyond that time; and whose orders to his cook were, not to inquire whether the company had come, but whether the hour had come.

H. C.

A GOOD CLOCK OR WATCH IS A GOOD THING.

The editor of the Farmer's Almanac somewhere passes off his jokes upon the Peter Foschins, who pride themselves upon their pocket timps with tow chains and rusty copper and colored glass trinkets. But there is a difference between a watch worn for use and one worn for show.

Some years since, having business with a Mr. B, I called at his house and inquired for him. His wife observed that he was at work in a distant field, but would be in at twelve o'clock, which was their dining hour. I concluded to wait his return. The dinner pot hung over the fire: at different intervals the various articles designed for the meal were put in: the time not occupied with this, was spent in sewing, till the hour to spread the table and make the other necessary preparations for dinner. A bowl of water and a napkin were placed upon the wash-stand, and at the hour mentioned, Mr. B. came in: after a few words, he washed himself; and now all things were ready, and we drew up to the table. The dinner was well cooked; nothing overdone by remaining too long over the fire; nothing spoiled by standing after being taken up; no complaints because Mr. B. had come home so late, nor because Mrs. B. had not got things ready on his return. The clock in the house agreed in time with the watch which Mr. B. carried in his pocket; while Mr. and Mrs. B., confident of this, and being in the habit of regulating themselves by these, did not subject one another to those countless inconveniences which grow up in families, because the wife never knows when the husband will be at home, and the husband never

knows when his meals will be ready. Some may calculate time without a watch more accurately than others, but very few can do it with such accuracy as to have the whole concerns of a family well regulated without one, or not in a very short time to lose more from loss of odd hours and minutes than the purchase of such articles of furniture amount to; to say nothing of numerous little collisions of feeling and the chagrin of disappointment arising from mistakes made in respect to the true time of day.

Among the first things which a couple setting out in life should furnish themselves with, are a clock to be kept in the house, and a watch to be carried when any of the family have occasion to be from home; and the seasons fixed for their regular meals, with specified times for other events, should be like the laws of the Medes and Persians.

But to revert to the family of Mr. B. My acquaintance with them continued during their life, (they are now gathered to their fathers,) and I often had opportunities of noticing the advantages of the strict regard which was paid to time; how much it facilitated the labors of the family, how much confidence it excited among its members, how it saved them from fears and apprehensions, how the delay of one member might thwart some of the plans and arrangements of the rest. Every one could fix a time when he or she would do a thing, or be at a certain place, or attend to an entrusted duty. Order, confidence, peace were in the family, as the fruits in part at least of the fact that neither Mr. or Mrs. B. had to guess the time.

How different, I have often thought, was it with Mr. and Mrs. G. They were naturally kind in their feelings, and industrious in their habits; but they did not succeed well in life, nor could it be said that they always manifested the best feelings or used the kindest expressions in speaking to each other. The fact was that Mr. G. had so often been disappointed in his plans by being obliged to wait for his dinner, and so often had an over-cooked or cold dinner, because either he or his "better half," or, as was often the case, both, had calculated wrong about the time, that his feelings had become fretted, his countenance soured, and his observations occasionally bitter, while the causes of a like character had been gradually operating, if slower yet not less surely upon his wife. Both felt in a degree injured, and though their better sense kept them from real outbreaks of passion and re-primand, they did not always meet with the most gracious look, nor speak to each other with the most acceptable words. The children caught something of the parents' spirit, and there was very little of the "dew of Hermon in that house."

A good clock in that house, and strict regard to its striking, would have spread much peace and comfort through the family, and the same amount of labor would have given him the real profit.

A wooden turrip for show may be folly in the pocket of the Foschins, but a good clock is a good thing. B.

THE DAY FOR LAZOR, THE NIGHT FOR REST.

This is the arrangement of Providence, and our observance of it in its leading principles is essential to health of body, strength of mind, and the most perfect exercise of the moral faculties. I do not believe that an instance can be found where a wilful and long continued departure from this principle has been indulged, and the transgressor not experienced some sensible inconvenience from it. It is no less important to the laboring part of animal creation than to man. I have many facts which I could produce as confirmation of this, but one among these will simply express the conviction of my own mind, as made

up from personal observation. For a number of years, I had occasion to travel considerably. I used my own horses. At first, if I had a long or hard day's ride to make, I was accustomed to rise quite early and go on some distance, feeding my horse or breakfasting myself; but finding, as I supposed, that my horses suffered inconvenience, and perfectly confident that I did myself from this course, I changed my manner, gave my horse time to eat, took my own breakfast, drove probably faster, and made shorter stops, the result of which was, or I was unaccountably deceived, my horses would get through the service with less exhaustion, and I am sure that I experienced much less fatigue.

There are other reasons, I know, beside the one first suggested, why travel must be more exhausting to the horses and labor of all kind to cattle in the night than the same would be by day: these come in as additional considerations, and should not be overlooked in reasoning upon the subject; but it must not be forgotten that the great governing consideration is to be found in the fact that the wise and benevolent Governor of the universe has so constituted the laboring portion of creation, that when the sun ariseth, they should go forth to their labor until the evening; while those who will sleep so as to gain the refreshment which this wonderful principle in our nature is designed to afford, must, as the apostle observes, sleep in the night. If Jehovah, in accordance to our necessities, does stay the evils which an occasional departure from this order would naturally produce, we have no encouraging grounds to expect he will do it when these departures are habitual or consulted. Therefore it must be an act of ignorant or foolish presumption for any to expect the best success in any business, while the laws by which God directs the universe are disregarded. Apparent exceptions there may be to this observation; these however, could the real causes of the exception be fully searched out, would be found to originate in other causes, and their existence not in the least possible degree to invalidate the general truth of the observation.

The laws of the physical, mental and moral world just as certainly bring poverty, in the wide sense of the expression, poverty in substance, bodily health, mental vigor and moral discernment, upon those who work unreasonably by night as upon those who sleep unreasonably by day; and there are as many considerations why persons should be regular in their hours of rest, as there are why they should be regular and fixed in their hours of business. The Maker of all has so planned his works, while the reason and experience of men both bear testimony to the general wisdom and goodness of such arrangements. B.

NOTICE.

The Fruit Committee of the Massachusetts Horticultural Society, will hold a meeting at the Rooms of the Society, 23 Tremont Row, on Saturday, the 14th instant, at half past 11 o'clock, A. M.

E. M. RICHARDS, Chairman.

April 15th, 1840.

The speeches of Hon. Mr. Webster and of Professor Silliman at the first agricultural meeting in January, at the State House, have just been published, with copious notes upon various important agricultural subjects, by Mr. Colman, the Commissioner. Mr. Webster's speech has been revised and rewritten by himself, at the request of the Commission, from the notes taken at the time and published in the N. E. Farmer. It will be found for sale at the New England Farmer office.—These speeches will, we are confident, be heartily welcomed by the agricultural community; and besides the instruction which they furnish, the personal influence of men so distinguished in the public esteem and regard, must contribute to elevate the profession and help to give it the high place in the estimation of the public to which it is entitled.—The notes contain nearly as much in type as the speeches, and are wholly practical.

BRIGHTON MARKET.—MONDAY, April 13, 1840.

Reported for the New England Farmer.

At Market 270 Beef Cattle, 23 pairs Working Oxen, 11 Cows and Calves, 150 Sheep and 1355 Swine.

Prices.—Beef Cattle.—Sales were quick without much advance. We quote a few extra \$7.00 First quality, \$6.50 a \$6.75. Second quality, — Third quality, \$5.50 a \$6.00.

Working Oxen.—Sales \$80, \$85, \$92, and \$110.

Cows and Calves.—8 des quick. \$25, \$32, \$37, and \$40.

Sheep.—All at market were ordinary and were sold at \$2.50 each.

Swine.—Sales quick at the prices obtained last week. Lots to peddle at 4 1-2 a 4 3-4 for sows, and 5 1-2 a 5 3-4 for barrows. Large barrows 5 and 5 1-2. At retail 5 to 6 1-2.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, work ending April 12.

BEAN POLES.

500 dozen of Bean and Dahlia Poles, for sale by **MOSSES FRENCH**, Maine Wharf, Broad Street, near the bottom of Summer St. April 13. At

Week's Treatise on Bees

For sale by **JOSEPH BRECK & CO.** April 15.

Fruit and Ornamental Trees, Mulberries, &c.

Fruit Trees of all the different species, of the most celebrated kinds. The Catalogue of Fruit and Ornamental Trees and Shrubs, Roses and Herbaceous Flowering Plants, for 1839, is ready, and will be sent to all who apply. In that catalogue the very best kinds of fruit, so far as proved, are particularly designated by a *.

Morus Multicaulis and other Mulberries, Cocks-pur Thorns, Buckthorns, Strawberries, Raspberries, Grape Vines, &c. &c. Poinas, Roses, Honeyuckles, &c.

All orders will be promptly attended to; and trees, when so ordered, will be securely packed for safe transportation to distant places. **WILLIAM KENRICK.** Nonantum Hill, Newton, April 8, 1840.

Scions of Fruit Trees Wanted.

The subscriber wishes to procure Scions of the following, for which an equivalent will be given in money or choice Scions.

Fruit Trees.—Early Bergamot Pear, of Cox's. Sheuk's Pear, from Pennsylvania, Burlington Pear, from Marpeta, Ohio. Green Sweet, Hightop Sweet, and Seek no Farther, of Thatcher's American Orchardist. Dartmouth Sweet Apple. Lewiston Egg Plum, Tomlinson's Charlotte, Gifford's Lafayette, of Prince's Pomological Manual. And all the Plums originated by Mr Corse, of Montreal, except the Nota Beaa.

ROBERT MANNING. Pomological Garden, Salem, April 8, 1840.

FARM FOR SALE.

The highly cultivated Farm of the late Captain A. Delano, situated in North Chapestown, N. H. four miles from the flourishing village of Claremont, containing 160 acres of first rate arable and wood land, with a well finished two story dwelling house with all necessary out buildings, unfading water at house and barns, two good farms, with shed 30 by 20 feet, and all necessary buildings for a well stocked farm; together with a good assortment of young fruit trees, among which is a fine variety of pear and apple in a flourishing condition, with two good gardens. Terms liberal. Apply to **H. F. DELANO**, on the premises, or **ISAAC HUBBARD**, 154, Chestnut Street, Boston.

North Chapestown, April 8, 1840. tfr

Isabella Grape Vines.

For sale by **JOSEPH BRECK & CO.** Isabella Grape Vines, of a large size, many of them having borne fruit the last season. March 25.

BONE MANURE.
A good supply of animal bones constantly on hand, and for sale at William Chace's mill, one and a half miles north-west of Providence Bridge.

A sample may be seen at Remington and Whitman's store, No. 32 Market St. Providence, R. I.
Also, Bone Mills on a new and improved construction, for sale at the above place. April 8. St

SPLENDID PEONIES.

AT REDUCED PRICES.
Parony Whiteleg, or "House Double White; Parony France, or Rose scented line Double Crimson; P. Humei, Double Chinese Crimson. All the three preceding at 31 each. Also, P. Tomblino or Single Crimson; Double Crown; Roseo or Rose Colored; P. Carna or Flesh colored; Alifloro or Single White; Double Crimson. An assortment of all kinds. **WILLIAM KENRICK.** Newton, April 8.

FARMING AND GARDEN TOOLS.

For sale at the New England Agricultural Warehouse and Seed Store, No. 51 & 52 North Market Street. 500 dozen Cast St-61 and other Styles.

300 "	Patent Syc the Snathes.
200 "	Common do. do.
100 "	Cast Steel Hoes.
200 "	Crooked Neck Hoes.
200 "	Common do.
100 "	Prog. do.
400 "	Garden do. superior.
500 "	Hay Rakes.
1500 "	Sythe Rifles.
900 "	do. Stenes.

MISCELLANEOUS.

TENDER HEARTED LANDLORD.—"James," said a worthy merchant on Main Street, to his clerk, the other morning, "go down to Water Street, to Mr. ———, and tell him his rent must be paid today. I can't wait any longer, as he's already two quarters in arrears."

The clerk obeyed the direction, and soon came back with great appearances of milkiness about the eyes.

"Mrs. ——— wants to see you, sir, about that rent, very much, sir."

The merchant happily was at leisure, and went at once to visit the tenant. He found him extended on a coarse bed, in an insupportable stage of a dangerous malady. His wife was busy over a scanty fire, apparently preparing some simple aliment for her husband.—Three little children sat shivering in the corner. His approach was unnoticed.

"Ma," said one of the little urchins, "when be you going to get breakfast?"

"Breakfast, my dear child, that is more than I can tell."

The merchant advanced.

"My good woman—my good woman—ahem—that is!"—and the worthy man felt very much like choking. He grasped his pocket book convulsively, and laid some bills upon the table—he opened the door, and disappeared.

"James," said he again to his clerk, "take this order to Mr. ———, and tell him to have the provisions delivered immediately."

The merchant felt much better than he would have done, if he had got his rent. There is something in a good action that makes one's heart feel lighter—warmer—better. We would publish the good man's name, but we know he would dislike it, and we would not for all the world offend him.

New York Paper.

THE CONTRAST.—B was an active merchant, distinguished alike for his accurate knowledge of his profession and his strict integrity. The best appointed ships, however, are sometimes wrecked, and plans laid ever so wisely, in seasons of panic and disaster often miscarry. B. failed, grew sick from too close attention to the studies of the counting room and died. His wife was left destitute; and of course friendless, and she had four young children to support. How could she do it? B. had been familiar with a distinguished merchant down town, Mr. A. T., who sometimes presided at meetings in the Tabernacle; and to him the young widow, who was an exemplary member of the same church as herself, applied for a credit of about \$500 worth of goods for six months. She had caused the lower part of the house to be fitted for their reception, and determined to turn her knowledge of trade to account in supplying her acquaintance with a particular kind of merchandise. The merchant gave no answer at the time; he would consider it; and put her off a dozen times, and then told her he would not grant the request.

There was an actor at Delmonico's a few mornings after, and he overheard a relation of the above circumstances, in a conversation between two gentlemen with whom he was acquainted.

"How is she now?" said the actor.

"In despair."

"Cannot obtain the money?"

"Nor the credit."

"Well, relying on the correctness of your representation, I offer a proposition. If you will each lend her \$250, I will lend her twice that sum."

They had no money which was not invested.

"Well, then, here is a check for \$1000—go and get the money, carry it to her, and take the note for it payable to yourself or bearer in one year. Bring the note to me, and mind that you say nothing of the source from whence the funds came."

His directions were obeyed. When the note fell due it was paid, with interest; and the widow is now doing a fair business on her own account.—The actor was **LOWIN FORESTER.**—*N. Y. Eve. Post.*

WINSHIP'S NURSERIES,

BRIGHTON, MASS.

The proprietors of this Nursery are now ready to receive orders for their extensive assortment of Fruit and Ornamental Trees, Forest Trees, Shrubs, Herbaceous Plants, Roses, Green House Plants, Vines, &c.

Orders from a distance will be properly packed to go with safety to any part of the United States, and will be delivered in the city free of expense.

The Nursery grounds are five and a half miles from the city, by the Worcester Rail Road; cars stop three times a day. Orders by mail addressed to Messrs. WINSHIP, Brighton, Mass., will be promptly attended to.

PEAR, PLUM, GRAPE VINES, &c.

2,000 Pear Trees, of the most approved kinds.
1,000 Plum Trees, of the most approved kinds and extra size—many of them have borne the past season.

500 Quince Trees.
3,000 Isabella and Catawba Grape Vines, from 6 to 15 feet high, most of them have borne fruit—Black Hamburg, Sweetwater, Pond's Seedling.
30,000 Giant Asparagus Roots.
5,000 Wilmot's Early Rhubarb or Pie Plant, lately introduced.

Also—a good assortment of Gooseberries, Roses, &c. of different kinds.

All orders left at this office, and at Gould & Home's Iron Store, 3 Faneuil Hall or with the subscriber at Cambridgeport, will meet with immediate attention.

SAMUEL POND,

Cambridgeport, Mass.

March 4.

SCIONS OF FRUIT TREES FOR SALE.

The collection of fruits cultivated at the Pomology Garden consists of more than 1400 varieties of the Apple, Pear, Plum, Cherry and Peach. Scions of all those which have been proved are offered to nurserymen and others.

Gentlemen wishing to send collections of American fruits to their friends in Europe can be furnished with most of those of first rate quality. They are warranted true to their names, and are in all cases cut from fruit bearing trees.

ROBERT MANNING.

Salem, January 28, 1870.

FRUIT AND ORNAMENTAL TREES.

JOSEPH BRECK & CO. offer for sale a great variety of Fruit and Ornamental Trees and Shrubs at Nursery prices, consisting of Apple, Pear, Peach, Plum, and Cherry of every variety.

Horse Chestnuts, Weeping Willows, Mountain Ash, Silver-leaved Alerie, Spruce, Fir, Larch and other Ornamental Trees.

Currants, Gooseberries, Raspberries, &c.
Also—Roses, Honeyuckles, Albicorns, Snowberries, Persian Lifes, &c.

Orders carefully executed, and the trees well packed, in such a manner that they can be sent without injury to any part of the country.

March 11.

FOR SALE OR TO LET.

A wooden two story house, with six acres of fertile land, situated in Medford, within half a mile of the village. Said house contains four rooms on the first floor and six chambers. The premises are plentifully supplied, with a variety of choice fruit trees, in a thrifty and bearing condition.

A portion of the land is a superior location for a shipyard. The above is a pleasant and desirable place for a country residence.

For terms inquire of JONATHAN BRIGGS, near the premises, or WILLIAM BRIGHAM, No. 35 Court Street, Boston.

March 25.

AGRICULTURAL AND HORTICULTURAL TOOLS.

Just received, at the New England Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, per Ship Chatham, from England, a splendid assortment of Agricultural and Horticultural Implements, viz.

100	dozen best Cast Steel Sickles.
50	" stout Cast Steel Brer Hooks.
25	" Breaking up Hoers.
5	" Pruning Chisels with Saws.
20	" pair Grass Shears.
25	" pair Pruning Shears, with slides.
25	" pair Ladies Ivory handle do do.
25	" pair Ladies Corro do do.
5	" Large Hedge Shears.
25	" Wakfield's Pruning Shears, with slides.
10	" Nine Shears.
50	" Large Planing Knives.
25	" Budding do do.
15	" Cast Steel Edging do.
5	" " Hay do.
40	" " Garden Trowels.
20	" Bill Hooks.
10	" Furze Bills.
10	" Gentlemen's Fringe Bills.
5	" " Horticultural Hatchets.
50	" Dutch Hoers.

April 1. JOSEPH BRECK & CO.

SILK WORMS EGGS.

The Eggs of the celebrated *Sua Silk Worm*, now offered for sale, were raised in 1839 by M. Canille Beauvais, superintendent of the experimental silk farm, established near Paris by the government of France. The *Sua Silk Worm* was introduced to France from China by Louis XVI. in 1784, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France.

Each sheet contains an ounce and is signed "Canille Beauvais." Price \$3.

WILLIAM KENRICK, Newton.

Or apply to JOSEPH BRECK & CO.

March 25.

April

FLOWER SEEDS—CHOICE VARIETIES.

JOSEPH BRECK & CO. have received a choice assortment of Flower Seeds from England and France, which, in addition to what have been raised under their own inspection, embrace the finest collection to be found in the country, including all the new Annuals, Biennials, and Perennials worthy of cultivation; neatly done up in papers at 6 1/4, 12 1/2, and 25 cents each. For sale at 51 and 52 North Market Street.

February 5.

SILK WORMS EGGS.

Just received, a few ounces of Silk Worms Eggs, from Smyrna, said to be of a superior variety. Price \$3 per ounce, clean seed.

JOSEPH BRECK & CO.

April 1.

FARM FOR SALE.

For sale, a superior farm of nearly fifty acres, between Boston and Lowell, 15 miles from the former place; on which is situated a convenient dwelling house, barn, and other buildings in good repair, and an orchard of choice fruit trees. For further particulars inquire of the subscribers, No. 52 North Market Street. JOSEPH BRECK & CO.

February 26.

FOR SALE OR EXCHANGE.

A valuable farm in Harvard, County of Worcester, the well known Bromfield Place; an excellent dairy farm, well wooded, the house spacious, fitted for two distinct families. The situation among the most pleasant to be found, especially for private or High School, bordering a part of the farm is a beautiful sheet of water, containing two islands belonging to the estate. Inquire of the Subscriber at South Natick.

March 4, 1870.

J. B. T. FLANCHARD.

Green House Plants.

Green House Plants of every description furnished at short notice, and well boxed, so that they may be sent to any part of the country in safety.

March 11.

JOSEPH BRECK & CO.

THE NEW ENGLAND FARMER

Is published every Wednesday Evening, at \$3 per annum payable at the end of the year—but those who pay with a sixty days from the time of subscribing are entitled to a reduction of 50 cents.

TUTTLE, DENNETT AND CHISHOLM, PRINTERS,
15 SCHOOL STREET, BOSTON.

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

PUBLISHED BY JOSEPH BRECK & CO., NO 52 NORTH MARKET STREET; (AGRICULTURAL WAREHOUSE.)

VOL. VIII.]

BOSTON, WEDNESDAY EVENING, APRIL 22, 1840.

[NO. 42.]

N. E. FARMER.

For the New England Farmer.

LETTER FROM WILLIAM FOSTER, Esq.
[Concluded.]

Cadiz in Spain, is a city of about eighty thousand inhabitants. It is a peninsula, and is separated from the main land by a barren neck of sand, seven or eight miles long, without a sign of vegetation, excepting where it has been created by the industry of man, and the elements in conjunction. This city is wholly supplied with vegetables, and chiefly with milk, by gardens made on this barren sand.—The city affords little mure, the streets being very narrow, and there being but few horses there.

These gardens are made level, and intersected by little gutters to conduct water into the beds, into which they are divided about 40 by 20 feet, hemmed round by little dams about 12 inches high. When the ditches are filled with water in the manner I shall explain presently, the gardener with his hoe makes a small gap in the dam and floods these beds, one after the other, and closes them when so flooded. This operation is performed once or oftener, in a day, according to circumstances. It must be noticed that there are six months of the year during which little or no rain falls in the south of Spain. But the water for this irrigation is drawn from wells in a very simple and cheap manner.—

Over the well there is a machine called *Norie*, consisting of one perpendicular wheel with projecting cogs, which gear into an old-fashioned lantern. On the opposite side of the cogs, stand off wooden spokes about 14 inches long; over these spokes hangs an endless band, composed of two parallel bass ropes; between these ropes there are fastened a number of earthen pots, which go down empty on one side and come up full on the other, and discharge into a trough, from which the little garden canals are supplied. The pots have a small aperture in the bottom, to allow the air to escape, while they are filling.

Notwithstanding the numerous hydraulic machines to draw water from wells, this, although the most ancient, is the most productive by any given power. It is still in use in Egypt and on the whole northern coast of Africa. This simple mill is turned by a horse, a cow, or an ass.

Here then is nothing but water, air, sun and sand to produce vegetables for eighty thousand inhabitants. I make no mention here of the shipping, which is very numerous, but leave that to balance the supply of vegetables which may come from more distant places.

I will mention one small experiment of my own. While in France, and a *quasi* farmer, I came in possession of a few potatoes from an English woeck, and planted them on a perfect swamp, barely strong enough to support a few wheelbarrow loads of barren gravel, which was near at hand. In these pots of gravel, which I made in imitation of the potato hills which I remembered at home, I planted

a few potatoes, and gathered an excellent crop of fine potatoes. Now these floating hills of gravel performed merely the function of a matrix, in which the vegetable congestion was performed: the *nourishment* of the plant came from the air and water; or their united powers decomposed a part of the gravel and a part of the bog, and prepared them also for vegetable aliment. I dwell on this subject for the purpose of fixing your attention to the very important part which air, light, heat and water have in vegetable formation. It will not be strenuously contended by any one that the lifeless gravel was, in this case, an important constituent of the potato crop. And if there be any analogy between the powers of animal digestion on living food, (which are said to be null,) and vegetable digestion, the living bog will not have afforded any nourishment to my potatoes, although the *decayed* portions of the bog might have contributed to it in some degree. Still there is scope enough left to show that water and air were the principal constituents. That water will produce solids, in a great variety of forms and substances, has been sufficiently proved in our own imperfect chemical laboratories. What wonders nature can perform with the same substance, we may never entirely know. But we find this important element in all her works; and none of them without some proof of its agency.

Stagnant water in a basin of inert clay, cannot remain long without discovering signs of incipient vegetation, in that green scum which soon appears; and soon after, without any apparent generative cause, animal existence becomes apparent.

Being now convinced of the vast importance of this great agent, let us keep our sylvan nets always spread, and ready to arrest it in its passage from the lakes and the ocean over the thirsty earth; and then let us economise it by all possible means; and not let it run too hastily to the ocean from whence it came, before it has paid its due tribute.

We often hear during great droughts, of water being so scarce that cattle must be driven miles to be watered. Now, it would be hardly possible to find a farm which presents some inequality of surface, where the superfluous water from higher grounds could not be conducted into a place of deposit below. There are thousands, even, which offer better places of deposit on high locations, in the gorges of hills, where a short dam would retain thousands of hogsheds of water, which might be used for irrigation, as well as for other purposes; and where water is at command, we have seen above, vegetable increase is certain. As it is well to mix a little practice with theory, I will relate the story of a small trial in this neighborhood and on a place not the most favorable.

A number of years ago, Mr Francis Amory, called upon me to visit his farm in Milton, to advise him about getting soft water for his house. This farm is near to the Blue Hill ridge, but is detached from it, and forms an insulated rising by itself, the greater part of the land being higher than the grounds about the house. We chose the lowest part of an adjoining meadow, near the house, for the place of our reservoir, over which the wash of

the higher ground in the rear naturally flowed, though not in the form of a brook, but quite imperceptibly, as on any moderate declivity. There we dug a reservoir about twelve feet diameter, and as many deep, and stoned it with common wall stones. From the house to this reservoir there was laid a lead pipe, for the convenience of pumping the water into the kitchen. This reservoir, I am almost annually informed by Mr Amory, has never failed in the driest seasons.

The city of Cadiz occupies less ground by three quarters than Boston, and contains about the same number of inhabitants. For six months of the year little or no rain falls there; yet the roofs of their houses furnish them water for all purposes but drinking. This water is conducted into stone tanks. It was on a suggestion of this fact, several years ago, that our city government adopted their present system of reservoirs, which may be made to furnish twenty times more than it now does, at a small additional expenditure.

There are situations where water may be easily collected, but from whence it cannot, without too much expense, be taken by natural inclination for irrigation or other purposes where it is wanted. But there are various modes of removing this water mechanically. Let us suppose that it is now wanted in a direct line over a rising ground of 20 feet elevation, to irrigate a meadow. The *Norie*, described above, would answer the purpose, but might be too expensive for our country. The *Hydraulic Ram*, of which I shall offer you a plan, would be less expensive of labor, but vastly wasteful of water; and is useful only to elevate smaller quantities of water for houses and stables. The *Syphon*, however, may be used to great advantage, under all elevations, which come within the pressure of the atmosphere, viz. about 32 feet; or where the crown of a hill may be reduced by a trench for the *Syphon*, to that elevation. This *Syphon* may be from one inch bore to any other convenient calibre; and will continue to run as long as there is any water in the reservoir.

It would seem, when we contemplate the expensive Roman aqueducts, that they were unacquainted with this hydraulic instrument. It was first applied upon a large scale in this country, I believe, at my suggestion, by the father of our present Mayor, at Charlestown, to draw water to a well in his distillery, from another well, several hundred feet distant; and afterwards on the Boston Hill Dam, for one mile. All over continental Europe, where the smallest spring can be found, it is used in succession by all who can have access to it, to make artificial ponds, where fish are raised for consumption. It would be an interesting question of rural economy to learn how much these ponds contribute to the food of man. The amount must be very great, but I do not remember to have seen it stated in the European statistics.

In that part of France where I lived, although the farms are very small, from ten to twentyfive acres, they obtain shelter for their grain and other low vegetation, and attract moisture from the air by the same means. These small farms are divid-

ed into small fields, each one fenced in by mounds of earth, supported by sods laid flat one upon another. These earthen fences are about six feet at their base, and five feet high; and are covered with a nine years' growth of scrub oak, hazelnet or chestnut. I say nine years' growth, because they are cut in rotation every nine years; thus yielding an annual cut for fuel out of nine fields; and yet retaining the advantages of shelter and attraction, for the whole farm, for a large part of these enclosures is always covered with a thick ledge of verdure of various degrees of elevation.

It is difficult to account for the great product of these small farms otherwise than by giving great credit to this mode of close culture. The arguments used in favor of it are these. These hot-beds or moist beds, as I may indifferently call them, retain all that is put on them, in manure, and the rain which falls in them has time to penetrate the earth, and does not run away laden with vegetable spoils. The driving winds cannot sweep off too suddenly the volatile elements of the manure, or exhaust the plants by too rapid breathing, or shake them too violently, and break or disturb their roots; and as for a general prostration, that cannot happen. Although the temperature is sufficiently high for vegetation, and more equable, the scorching midday sun is mitigated. No drenching showers can here carry away the seed, and the soil.

To form an opinion of these little farms, it is enough to know, that their occupants, who before the revolution never owned them, and now, not commonly, pay first rent to the landlord, then very high direct taxes, besides an infinity of indirect impositions; such as the tobacco tax, even on that which they raise; or on their own wine, on a certain quantity of salt, whether they consume so much or not; and after all, on the very articles they carry to market, they pay an excise city duty. To do all this, on a farm of fifteen acres, and raise three or four horses, a yoke of oxen, several cows, pigs and poultry, is evidence enough of a very productive system of culture. Yet their instruments of husbandry are very inferior to ours. On the seacoast, besides kelp and seaweed, they draw from the sea a calcareous substance, about the size of coarse gravel: it is the exuvia of shellfish, I believe. They obtain this substance with what the fishermen call a drag-net. It answers the double purpose of plaster, chemically, and sand, mechanically: it mellows and loosens the soil; also like lime and salt, attracts moisture, to aid in the decomposition of every thing which may enter into the vegetable construction.

The roots of the trees which cover closely the earthen fences, contribute to hold them up; and they require but little repairs in the spring. Thus much for close culture.

Extremes are sometimes used by logicians to prove cases; and I would be allowed this privilege in this case.

The once fertile and cultivated northern shores of Africa, are now a barren wilderness: the once productive plains of Spain now produce nothing.—These sites were once measurably protected by vegetation of a lofty growth. This was, in a degree, a system of close culture. From the barren condition in which we find them now, to the close culture in France, just mentioned, are my extremes. The gradation from one to the other has been a matter of necessity, growing out of the increasing wants of an increasing population. Science has no initiative merit in this affair; otherwise than as

all science is derived from experience. But we do learn in these extremes one useful lesson, which is, that vegetable substance is susceptible of great increase, independently of manure.

However little credit may be given to that theory which assigns such important powers over the vegetable creation as it has been attempted here to find in forest trees on high lands, especially, it requires not much credulity or forecast to believe that wood of itself, must become more valuable every year, so long as our population is on the increase. It is a silent, ever-growing crop, which requires no labor, not even fencing, after it has got out of the reach of cattle. In the circuit of about fifteen miles about Boston, I am informed by one of the most observing and intelligent landholders of this state, that woodlands increase by their growth about fifteen per cent. If this be near the truth, putting the annual increased demand out of the question, it would seem, that this is a very great interest.

To talk of an annual crop of wood in this country of rapid movements, and of impatience to enjoy precocious fruits, would be idle. Fathers are too apt to think that no heritage is so good for their children as a little ready money, or stocks which yield a semi-annual interest; yet how many have paid dear for this opinion. My father-in-law planted about five thousand forest trees annually, and had for sale an annual crop of full grown timber. How could he do this, it will be asked: why, because his predecessors did the same before him; and his successor is now, I trust, following the same practice.

It has appeared wonderful to Englishmen and Americans, that such a population as that of France could be supplied with wood fuel. In addition to the wood raised in the manner described above in Brittany, there are forests of various dimensions, all over France; some owned by government and others by individuals. These forests are of two kinds; the one called *Bois de Haut Futaie*, or full grown trees; and the other *Bois Taillis*, or wood of nine, or eighteen years growth, according to the usage of different provinces. These forests are divided by cart-ways in measured sections, and are commonly sold at auction when of the given age. Thus the proprietors have an annual crop without labor or manure; and thirtythree millions of people are supplied with fuel. The lands destined for this purpose are generally such as are least suitable for cultivation, although there is much good land covered with wood. These forests require no planting; they grow spontaneously, as the lots stripped of their wood are protected all round by other lots in full growth. The plantations made by my father-in-law, are border and ornamental plantations, dividing the fields of a large estate. In making his transplantations from his nurseries, I observed that he was particularly careful to mark each tree, so as to give it the same exposition in its new bed as it had in the place where it was raised.

Foot Rot in Sheep.—The Maine Farmer gives the following remedy for this disease:—First, cut away, with a sharp knife, the horn of the hoof, and let the part diseased bleed freely; then cleanse it well with soap suds; then take blue vitriol, make a strong decoction of it in water or spirits, and plunge the foot in it, or apply it faithfully to every part. This should be done frequently, and care be taken that no dirt get into the diseased parts.

For the N. E. Farmer.

SCIENCE FOR FARMERS.

To witness the improvements which have been made in agricultural implements, it is only necessary to contrast the most finished and convenient ones of modern times with the clumsy, ill-constructed accoutrements of the ancients, or indeed of the nations of modern times who are pursuing the dark and luckless paths which have been travelled by their ancestors from time immemorial. Thus we see the finished and well executed plough of modern days, a beautiful and useful improvement upon the unsightly, ill-contrived, and vexatious working implement of the middle ages, when a strength of man and beast was necessary to subdue the soil, which would ill become the labor saving propensities of the nineteenth century. We may carry the contrast further, and witness the more visible difference between the ploughs even of those dark and distant days, and the pick-like instrument with which the nations of earth's morning broke the soil.

But we need not unshroud the past nor remove the veil from the sepulchre of buried ages, to witness the march of improvements to which "the earth which calls the harvest forth" is daily becoming more and more subjected. Take the world as it is (and it is certainly a "matter-of-fact" world), and we have sufficient evidence. Compare the agricultural implements of those parts of the United States where agriculture has been carried to the greatest perfection, and of England with those of other nations. As we have begun with the plough we will not look back from it, but consider the difference between those which "leave the glebes" around us, and those of some other countries. Take China, where, as Loudon says, "agriculture has in all ages been encouraged and honored," where "the emperor once a year holds a plough in the presence of his subjects;" and the article (a specimen of the whole) thus guided by his royal hand, is said to have but one handle, no coulter, to be drawn by oxen, sometimes by women. It is described as possessing all the rudeness which the state of a nation like the Chinese would naturally warrant. Go Egypt, and we are assured of finding ploughs and other implements of the rudest kind. The common plough of Castile, Spain, is supposed in kind to be the same as was used by the old Romans, which that of Valencia is said to approximate very nearly to the one described by Virgil almost two thousand years ago. What an excitement one of these articles would create, if exhibited at a New England ploughing match! What wondering would arise if a New England farmer should assert his intention to till the earth with such a thing! The public voice would rise unanimously against him, and public opinion would declare him to be so furious mad as to render his going at large dangerous, and adjudge him a fit subject for commitment at the Worcester lunatic hospital. But we will take one step more in representing the horrible. In Poland, where the peasant acts as plough-maker, wheel-wright, &c., it is not unusual to see a plough constructed of the trunk of a young fir tree, a rod supplying the place of a share, and the trunk of the ploughman's handle, with a cow attached as team. The ploughs of Russia and the countries of the north of Europe, have a rudeness in the construction which would forbid a Yankee to guess what they are.

We have named only a single article of husbandry

ry in the models of which improvements exist, in proportion to the advancement of the nations where they are to be found in civilization, refinement and the arts. We might go through with all the et ceteras of agricultural labor and improvements, and find a similar state of things existing with regard to carts, wagons, ploughs, hoes, spades, scythes, indeed every thing which is brought in the culture of the earth, and the ingathering and securing of its crops. Now the problem for solution is, whence come all these differences? Why does not the Chinese throw away his plough, formed from a model as old as his empire, or the Polanders et his fir-tree grow, root and branch, and adopt the light, thorough working, labor-saving, cast iron plough that we of these regions of the setting sun so much admire? Simply because they know no better. Guided by a sort of instinct in these matters, they seek no better things. They are, in fact, very much like the Dutchman, who put his bushel of corn in one end of the bag and a stone of equal weight in the other, to balance it, and threw it cross his horse to carry to mill. On being enquired why he did not throw away the stone and divide the corn in the bag so as to balance itself, he replied, he had never thought of that, but as his father always used the same stone for similar purposes, he was sure it was the best way. Such is the case with nations and individuals, who pass long in the old rutted track of their ancestors, with regard to improvements in agricultural implements. They know of no other—seek no other way. But how are these improvements brought about? Just as are those in navigation, travelling by land, propelling machinery by water or steam, or any thing else is accomplished—by the application of science to the completion of the object; and the effects of it are as positive and as useful in the construction of the humblest tool which the laborer uses in cultivating the earth, as in building steamboats, railroads, introducing labor-saving machinery into manufactories, or “for any other purpose or purposes whatsoever”; because these improvements enable the farmer to perform more labor, cultivate more earth, and do it better than it could be done under the discouraging circumstances which bad soils would necessarily create.

In proportion as the earth is thoroughly cultivated its productiveness is increased; consequently the farmer receives greater returns for his labor in ratio to the number of his acres, and in the same proportion the surplus for public demand is increased; so that the benefit of this improvement is not restricted to the farmer, but extends itself through every nerve and muscle of the body politic, insomuch that all classes of consumers share its good effects.

We are well aware that it may be said that farmers are not plough-makers nor wheel-wrights, nor any of these things; that it belongs to the artisan to invent and fabricate his implements. Admitted, the mechanic must manufacture the tools of agriculture. He can do it cheaper and in a more workmanlike manner than one unaccustomed to such employments, and by so doing the obligations of trade meet a happy reciprocation. But then the farmer is the only true judge of the merits of a plough, whether in all its particulars it is most admirably adapted to operate successfully in this soil or that; or in the construction of a wagon or cart, whether one of this construction can be most easily drawn over his fields and the highways adjacent thereto, or whether a variation of structure would not be

desirable; and when he has ascertained the fact to his mind's satisfaction, which may be done by models, he may go to his artisan and have one constructed accordingly. Hence we see the propriety of the farmers understanding the science of mechanics, one which is by no means restricted to the things herein specified, but as having an extended effect in his operations—in the construction of gates and bars—in building walls—opening drains, locating and working highways and private ways,—indeed in almost every thing.

The location and construction of roads is a matter of interest to all men, whether of business or pleasure; to the teamster who moves his heavily laden cart sluggishly along, and the bearer of the express which requires despatch. In hilly regions, where roads must of necessity pass over many of “earth's protuberances,” it is certainly an object to secure their location in such places as that a team will haul a given burden over them with the least fatigue; humanity and interest, the great mover of human effort require it; and in these rises and descents, must be performed on an inclined plane, more or less perfectly constructed. We have sometimes seen instances where this was done in the worst way imaginable. It was like passing over the bail of a kettle: sometime almost perpendicularly and then nearly horizontal. There is no necessity for such roads. They are laid out and wrought by no fixed principle. The inclination of the plain might invariably have been so regular as to have been overcome with comparatively perfect ease, insomuch that great labor will be saved in moving a given weight over them.

These swamps, too, are all of them one duty to be cleared of their superfluous moisture, and for their owners the sooner it is done the better, for they are certainly in many instances, his deepest, richest soils. One of them in the neighborhood of where we write, over which the western railroad is now building, has been fathomed sixty-five feet, and there are others around us of less depth of pure mould, and many of them of nearly a water level. How shall the water which is so abundant in them, be most successfully taken off? Drains must be constructed to collect and carry it away we know; and that a proper construction of them to do so, is evident; and the utility of the knowledge of hydraulics in giving them a right location and structure, is fact positive.

It may, to be sure, so happen that farmers are not their own ditchers: very seldom that they are, and while the present influx of foreigners, among whom there are so many who can do faster, cheaper, and in many instances better than himself, continues, he will probably find it to his advantage to employ them in these services; yet it is for him to make the draft and give the plan of the work; and if a total failure result, he may give credit to his own ignorance.

The same science which applies to draining lands, by a change of causes calculated to produce alike beneficial effects, teaches the best mode of irrigation,—a method of watering dry territories not so much practised among farmers at present as it should, and eventually will be. How much of the wealth of barnyards is now utterly lost to its owner in consequence of being allowed to evaporate or pass into the atmosphere, or what is worse, pass off into the highway to create mud, to the great annoyance of man and beast, or to some field or land where no salutary effect can be produced from its action? And on our highways too, how often, in

time of showers, do we see the accumulated waters allowed to course the distance of half a mile or more—not only opening hideous gulleys to entrap the traveller, but bearing a wealth to annihilation, so far as useful purposes are concerned, which, if it had been taken from the road at proper distances and turned upon the neighboring fields, would have given them a wealth indeed, more than sufficient to have compensated the owner for his trouble, and to some extent would have abridged the vexation of raising an enormous highway tax, while the traveller as he jogged smoothly and easily over a highway, which by such care and attentions almost always kept itself in good repair, would mentally at least, express his obligations while passing along, and when he had, after the journeyings of the day are ended and he seeks repose, instead of dreaming of the horrors of an inquisition or the tortures of the knot, the airy vigils of his midnight slumbers would lead him through arcaean groves, beside still waters and flowery fields.

Yours, truly,
Mount Osceola, March 28, 1840. W. B.

The subjoined is a well written and instructive essay on the raising of poultry, by one who evidently has some practical knowledge of what he is writing about. We hope soon to hear from our friend Hunt, of Pennsylvania. We trust our readers will not think that the hens make too much cackling in our paper of late. If any married man complains of this, we shall know very well that he is henpecked, and is a little disturbed at finding the same dish abroad that he is obliged so often to sit down to at home. We know our Hingham subscribers will not find fault—where, good careful souls as we know them to be, they never suffer a hen to quit the house in the morning until she has paid for her night's lodging, “cash down.” H. C.

From the Yankee Farmer.

P O U L T R Y — E G G S .

Among all nations throughout the globe, eggs and poultry have long been used, and highly prized as articles of food. But for lack of information, or the bestowal of proper attention in the management of fowls, the small quantity and high price of eggs in New England markets, during the winter season, cause most persons in moderate circumstances to do without them, while those of larger means use them as expensive luxuries. This, it is believed, is quite unnecessary; and as the Yankee Farmer is ardently devoted to all good improvement, I propose to give in its columns, a few practical hints, which are the result of personal observation and experiment.

The first important requisite in *henology* is, to provide suitable shelter. As cheap and good a method as any is, to erect a shed or “lean to,” attached to a barn or other building; the size for thirty hens and three protectors of the flock, should be twelve feet long and eight feet wide, with the earth for a floor. The south side should have rather large openings for glass windows—(these windows may be used for the hot-bed in the spring and summer)—in the winter, and grates in the summer. At the north side of the room, there should be built at one end, rows of boxes for nests, the number of nests to be about three-fifths of the number of the flock, leaving a small passage near the end wall, just sufficient for a person to pass between

the wall and the edge of the nests, for the purpose of sweeping, cleansing and white-washing it; and allowing the nests to project into the room in the centre, where they should be well boarded and secured by lids to cover the nests from sight. The passage spoken of would form a sort of alcove, with the nests presenting a front towards the wall; but by lifting the lids of the nest, a view of the nests may be had, and the eggs obtained from the back of the nests towards the centre of the room. This passage should be guarded at the entrance by a door with an aperture at the bottom, sufficiently large to admit the easy passage of the largest number of the flock; and should also be lighted by a small window in the north end. The hen is a proud and delights in secrecy and mystery about her nest, and if watched, and without the advantages of such concealment as is agreeable, will cease laying.—She is, moreover, like certain politicians in public life, delighted at the chances to “dodge” and to please her in this particular, an aperture should be made near the floor at the north end of the passage for her to retreat into the centre of the room, so that on finding herself pursued in the passage, she may dodge out, without being obliged to fly over the person's head or between his feet. This method of arranging the nests secures all the desired advantages of secrecy and security, although the hen were as fastidious as a hypocrite.

The hen-house should be provided with large boxes, which for thirty hens, should be each about three feet square and one foot high. One to contain wheat or corn and oats; another, dry sandy soil and wood ashes; another, old lime, mortar, small light colored pebbles or gravel, pounded crockery, glass ware, bones, and clam and oyster shells; all or either of them, as they may be convenient; and the other to receive the crumbs from the kitchen. A trough cut from solid timber, will be found the best vessel to contain water, as it will not be likely to leak, and in the winter season the ice can be cut from it without injury.

Neither of the boxes should ever be filled more than half full, or suffered to become quite empty; for if filled, the hens will waste their food—and if allowed to become empty, they will miss their supply of food, and when again supplied will eat too much, in expectation of another similar famine.—By keeping a supply before them they will pick what they need, consume much less food, and keep in better condition than when fed occasionally, though plentifully. The soil and ashes are necessary for the hens to dust themselves in; and the lime and pebbles, to aid in the digestion of their food, and to supply shells to their eggs.

Hens suffer from vermin when shut up in filthy pens, and care should be exercised to keep their room clean and sweet, by sweeping, changing the litter in the nests, and whitewashing every part in a thorough manner. A sick hen is always dirty, and a dirty hen is very liable to become sick. The cottagers of Scotland always have eggs in abundance, and of superior quality; and the reason assigned is, that the hens share the dwelling of the owner, and lay their eggs among the clean straw of the children's crib.

There should be affixed near the roof of the hen-house, several poles for roosts, under which should be a scaffold for holding the manure. This manure is highly esteemed by many as a dressing for onion beds, and I believe is sometimes used in the arts. At one corner of the room there should be a ladder, reaching from the floor to the ends of the

roosts, at an angle of about forty-five degrees, for the accommodation of young pullets and heavy old hens, and for those who, for reasons best known to themselves, come down from the roost at too late an hour for them to fly to their places again.

When the owner desires to raise chickens to increase his flock and supply his table, the period from the last of March to the first of June should be taken for setting the hens, and a larger number of eggs than usual allowed to remain in the nest.—When a hen clucks, and remains on the nest, instead of allowing her to set in that situation where she will be constantly liable to disturbance from other hens, I prepare a hard smooth nest in a box, in which I place the eggs, and in the evening I raise the hen, remove the eggs that are under her, put the hen in the box I have prepared, and the box in the original nest. By the next evening the hen has become attached to her new nest, which may then be removed to some secure place, away from other hens, and where she may find room for exercise and a supply of food and drink. I have frequently used empty flour barrels as shelter for setting hens, by turning them down upon the side in the yard, and placing the box inside. There is quite a benefit in setting a number of hens at the same time, as advantage may be taken of their simultaneous hatching to put two broods of chickens to one hen, and remove all the unhatched eggs to the nest of a setting hen, as there is frequently several days' difference required in perfecting the operation of hatching. The depraved disposition and careless habits of some hens at times, makes such a course desirable, as they appear to be entirely deficient in the organ of *philoprogenitiveness*.

Chickens may be weaned when from four to six weeks old, by providing them with an enclosure to protect them from the attacks of the older fowls, who acknowledge no right but that of might; and also, so far removed from the mother hen as to be beyond the sound of her clucking. Without some efforts to wean the chickens, the mother hen will keep from laying a long time, and labor to procure subsistence for her brood when there is no occasion for it.

When it is desired that a hen should not set, although disposed to do so, it is only necessary to confine her with one or two others and a protector, in a box having grates on one side, and feed them well for two or three days, when she will return to laying again.

I have already intimated the food that should be furnished to hens, but that I may be distinctly understood, I will state my own practice, and some of the results. I procure pinched wheat and seeds thrown out by the cleansers at a flour mill, for the principal food of my hens, throwing into the box occasionally, a peck or two of corn and oats. For my chickens, I prepare a dough of boiled potatoes and corn meal, until they are a week or two old, when I feed them with wheat and such crumbs as are made in the kitchen. With this method of feeding, I have obtained from something less than one hundred and fifty laying hens, over nineteen hundred eggs in the month of January, a month selected as usually the most unpropitious in the year. My estimate of the cost of eggs through the year, is four cents a dozen; and chickens weighing one and a half pound each, six cents.

In my management of hens, I find great pleasure as well as profit. It is my invariable practice, in my visits to the hen house, to treat them with a little music, in the way of a familiar whistle. This

becomes to them, in a short time, a well known call and I have often “put out my whistle” in a hearty laugh, to see my flock of nearly two hundred fowls flying towards me from all directions, when I have whistled for them. To make this signal effective a few crumbs or grain should be thrown to them as an encouragement. In the winter I never allow my hens to go out upon the snow, excepting in moist warm days; and in the summer I let them out every day just before sunset, when they hurriedly range through the garden in search of bugs, grubs and grass, but are too sparing of time to attempt scratching the beds.

Willis, in one of his letters published in the New York Mirror, gives an amusing and graphic description of the character and habits of a protector of a barn-yard flock. But divested entirely of the ideal there will be found as great a difference in the health, habits and disposition of different hens, as in their size or color. These differences may be easier learned and better understood by the attentive observer, than they can be described. Of the breed of hens, however, I give a decided preference to what is called, for what reason I know not, the Poland hen.

With such arrangements as I have mentioned or a similar plan in a barn or wood shed chamber every family in a city or village, may, at a trifling expense, keep at least twenty hens, that will furnish each year about three thousand eggs, and not far from two hundred plump, full grown chickens for the table. Yet farmers and others have kept hens ranging through their barns, destroying their hay and grain, and scratching and destroying their gardens, proving an unprofitable pest to themselves and a nuisance to their neighbors, when by proper management all these troubles would be avoided, and the fowls would form a source of enjoyment and profit, of too much profit for any thrifty farmer or good natured married man to dispense with.

Bangor, March, 1840.

J. S. S.

For the New England Farmer.

ENQUIRY.

Some twenty or thirty years since, I recollect having read an account of a great hunting or shooting match, which the inhabitants of Rowley and vicinity held, perhaps a century since. At that time a very great number of birds, squirrels and other creatures were killed. Their success was the subject of general congratulation, supposing as most did at that time, that these creatures were the greatest enemies which the farmer had to contend with, and thought that they could now look forward for crops greatly increased for several years if not through future generations, as it was not likely these would soon if ever become so numerous again. But the result was, as every well instructed man at the present time would expect, that the next year every kind of grain and fruit fell a sacrifice to worms and insects,—a less obvious but a much more powerful and unmanageable part of creation—the locust, the canker worm and caterpillar, each devouring what the other had left. The account of this was to me highly interesting at the time, and I should be very glad to see it again, not only because it was a very well written article, containing many observations of much practical utility, but because if brought before the public again, I must think it would help forward a change in public sentiment and practice, which is certainly

going on yet very slowly;—a change no less important to the interest of agriculture than to the high and benevolent feeling of an enlightened and sanctified heart.

I have kept my mind directed to the subject for many years, and have had conversation with many enlightened and observing persons in different parts of the state and nation, and am constrained to believe, that while there may be occasionally in some places an undue proportion of some kinds of birds and other creatures, who subsist much if not mainly on worms, insects, &c., and that sometimes there may be a lack of food for them, as there is occasionally for man, and that in consequence they may be driven to use very unceremoniously the grain and other kinds of produce which men were cultivating for their own use, yet, as a general fact, the number and variety of birds is at present much less through the country than the true interest of the farmer calls for, and that the killing them, as is ordinarily done, for sport, is an act as contrary to true wisdom as it is full of wanton cruelty; and I think that an observation which has been made is susceptible of as clear proof as the nature of the case admits,—which is, that the farmer who destroys a bird, loses thereby a peck of grain and a bushel of fruit, and robs his neighbors of twice that amount; while he who cultivates no land and yet sports himself in their destruction, does his citizens a wrong for which he can make no just and adequate restitution.

The leading object of this communication is to inquire if any one recollects the account referred to, or can give information through your paper where it can be obtained.

B.

THEORY OF DEW.

Notwithstanding the researches of Dr Wells, and others, upon the subject of dews, there are many who still remain either in total ignorance of the principles of the deposition of the moisture, called dew, or hold to the old theory that it is caused by the *air alone becoming colder*. The ancient Greeks observed the fact, that dew was deposited in clear nights, and not in windy or cloudy ones, and every barefooted boy who goes out early in the morning, knows that it is much more abundant on the grass by the wood side, than it is upon the sand or gravel in the road itself. Dr Wells, of England, made many experiments upon the subject; and from the facts thus ascertained, explained the cause of the phenomena, in a treatise which he published some time ago. He ascertained the cause of the deposit of moisture in the form of dew, to be the radiation or throwing of the heat imbibed by the sun, which thus cools the particles of air that come in contact with it, and causes the moisture which is in the warm air to be condensed. It may be well, for the better understanding of the theory, to state, in the first place, that as all bodies receive heat more or less easily, so they part with it, or radiate it more or less easily. Some bodies will part with, or radiate the heat which they have received, as fast again as other bodies. Hence they become cooled before the others. Warm air will hold more moisture than cold air: therefore, the body which radiates heat fastest, becomes cool first, and cools the particles of air which surrounds it, which deposits the moisture or dew upon it first. Grass parts with its caloric, or heat, much faster than sand or gravel—hence it has more dew upon it.

The following experiments may not be uninteresting to some of our readers. After a long period of drought, when the air was very still, and the sky serene, Doctor Wells exposed to the sky, twentyeight minutes before sunset, previously weighed parcels of wool and swandown, upon a smooth unpainted and perfectly dry fir table, five feet long, three broad, and three feet in height, which had been placed an hour before, in the sun-shine, in a large, level grass field.

The wool, twelve minutes after sundown, was found to be fourteen degrees colder than the air, and to have acquired no weight. The swandown, the quantity of which was much smaller than that of the wool, was at the same time thirteen degrees colder than the surrounding air. At the same time, the grass was fifteen degrees colder than the air four feet above the ground. From such experiments, he established the proposition, that bodies must become colder than the surrounding air, before they become dewed.

He also explained the reason why there was no dew in cloudy nights. It is because the clouds act as reflectors, and throw the heat back again; in the same manner as the bright tin top of a tin baker throws down or reflects the heat down upon the bread. A blanket, or umbrella, put over any body, would prevent the dew settling on that body for some time, although it was falling all around it.

On this principle, vines, and other things, are protected from frosts, by putting a blanket or covering over them, at night.

Frost is dew, frozen. By putting the covering over the body, it reflects heat back, and prevents, for some time, the dew being deposited upon what it covers.—*Maine paper.*

From the Farmer's Cabinet.

QUINCE TREES.

The cultivation of the quince is much neglected, though it may be justly ranked among our most valuable fruits. For preserves, it has long maintained a distinguished rank, and the fruit either in a green or dried state, is not surpassed by any other article for communicating a pleasant and agreeable flavor to pies made of apples. It is easily propagated by layers and also by cuttings, and any approved kinds may be perpetuated by grafting in the usual manner.

It produces the finest, fairest fruit when planted in a soft, moist soil, in a rather shady or sheltered situation. It keeps well if properly managed, and always sells for a very high price; the markets never being overstocked with them, as is the case with many other fruits in plentiful seasons.

The quince derives its name of Cydonia, from the town of Cydon, in Isle of Crete, whence it was originally brought. There are four kinds of the quince;—the pear quince, from the resemblance in its shape; the apple quince; the Portugal quince, which is less harsh and more juicy than the two preceding kinds; and the eatable quince, which is less astringent and milder than either of the other kinds enumerated. The trees being small, they can be planted ten or twelve feet apart along fences, or in places where they won't interfere with other tree, or the business of agriculture.

It is hoped that the present season will not be permitted to pass over without the cultivation of this valuable fruit being considerably extended among our farmers and gardeners.

PHILIP.

EXCRETIONS OF PLANTS.

The following notice of some of the substances excreted by the stems and leaves of plants, is taken from a work of Prof. Lindley: "Acid excretions are formed by the hairs of the chick-pea, the stag-horn sumach and some other species; and it is supposed that the singular property which some lichens possess of imbedding themselves in calcareous rocks is owing to their excretion of oxalic acid. The stinging power of the nettle is produced by an acid matter excreted by the hairs with which their leaves and stalks are covered. The nettles of Europe simply produced an uneasy sensation, but some of those of India have brought on lock-jaw, and even death itself by the torments which they inflict. A discharge of sticky matter by the hairs or by the bark of plants, is of very common occurrence. It is this which gives their viscidly to such plants as the rose acacia, to the buds of the horse chestnut, and to the young leaves of the torch tree. In many cases this sticky matter is analogous in composition to common bird lime.—Wax, or some substance analogous to it, is of very common occurrence on the surface of plants. Saccharine matter, in different forms, is also a common excretion from many plants. European manna is discharged by the flowering ash (*fraxinus ornus*), either in consequence of wounds artificially inflicted on the branches, or of the puncture of insects. The manna spoken of in scripture is yielded by a species of tamarisk, and by the camels-thorn, a plant which is common in the deserts of southern Asia. But the most curious instance of matter excreted from the leaves, is afforded by the fraxinella. The leaves of this plant are covered with little brown glands, which excrete a species of volatile oil. In warm weather this oil is converted into vapor and surrounds the plant, as an inflammable atmosphere, readily taking fire when a flame is brought in contact with it, and burning without doing any injury to the plant."

The possession of the power of rejecting such matter as is found unsuitable for their nourishment, would seem to be a necessary condition of the life of plants. Did they not possess it, their vessels must soon become clogged, and rendered unfit for performing their appropriate office. From some experiments which have been performed, it would seem that plants possess the power of disembarassing themselves of all kinds of matter which are found unfit for their nourishment. Macaire took a plant of mercury (*mercurialis annua*), and having divided its roots into two parcels, introduced one of them into a glass containing a weak solution of acetate of lead, and the other into a glass of pure water. At the end of a few hours he found that the glass of pure water had become perceptibly tinged with acetate of lead, which of course must have been taken into the circulation by the roots on one side of the plants, and thrown off again by the roots on the other. In this instance the excreted matter was thrown back without having undergone any change; as a general thing, however, this is not the case; thus, leguminous plants, of which the pea may be mentioned as an example, although they absorb only carbonic acid and water, will excrete the elements of those substances combined so as to form a species of gum. Grasses excrete principally certain alkaline and earthy muriates and carbonates, but very little of any gum.—*Farmer's Register.*

Be always at leisure to do good.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, APRIL 22, 1840.

TRANSACTIONS OF THE ESSEX AGRICULTURAL SOCIETY—1839.

We have much pleasure in announcing the appearance of the annual publication of the Essex Agricultural Society; a pamphlet of about 150 pages, and full of interesting matter. It embraces the excellent address of Allen Putnam, Esq., of Danvers, which we have already given to the readers of the N. E. Farmer, and which we know they must have perused with instruction and pleasure; and various reports of their committees on manures, on milch cows and heifers, on the diseases of animals, on reclaimed meadows, on the dairy, on fruits and vegetables, on domestic manufactures, on ploughing, on working stock, on forest trees and mulberry trees; to which is added the Commissioner's report of the first agricultural meeting, held at the State House in Boston, the current year, containing Mr Webster and Prof. Silliman's speeches on that occasion, with copious notes on housing sheep, on cultivating turnips, on draining, on redemption of peat meadow, on irrigation, on cultivating the bean and the tare, on the product of sheep, and on agricultural statistics.

These together constitute a valuable pamphlet, and add to the obligations which the public are already under to this exceedingly well-managed and useful society.

This periodical publication of the transactions of the Society, is one of the most useful measures which could be adopted by them to promote their objects; and the members of the Society are not insensible how much they are indebted for it to the intelligence, zeal and indefatigable and public spirited efforts of their secretary, to promote the agriculture of the county and the prosperity of the Society.

It is very much to be wished that the other societies in the commonwealth would adopt a similar plan, in order to preserve their often highly interesting reports.—These pamphlets in the first place, embody much valuable local information. They serve in the next place, to give a permanent record to the names of the successful competitors for premiums. In the next place, they bring the society more constantly before the public and excite a strong interest in its concerns. This must often serve to remind its members of their duty to the society and to the subject; and lead likewise, to a regular increase of members.

We shall take leave here to repeat suggestions which we have often made, respecting the form in which premiums are generally distributed by our agricultural societies. With the exception of the Berkshire Agricultural Society, they are usually given in money, without any formality whatever. The name of the successful competitor is barely announced, and he calls quietly upon the Treasurer for his money, which commonly goes at once into the general purse for expenditures, and is seldom heard from or thought of afterwards. Not so where the premiums are bestowed in the form of silver plate or some article of value with the name and occasion endorsed. Then it is preserved and shown with honest pride in the family, and is transmitted to others, and operates as a constant incentive to excellence. In Berkshire the premiums are given, where it can be done, in public, at the close of the annual address. This has an exciting and excellent influence.

We shall give to the public such extracts from this pamphlet as are likely to be interesting; and begin with the publication of a valuable paper from Mr Keely, of

Haverhill, on the subject of ploughing in green crops for manure. H. C.

[From 'Transactions of the Essex Agricultural Society.']
ON TURNING IN GREEN CROPS AS A MANURE.

The committee on the subject of turning in green crops as a manure, report:

That they have examined Mr Keely's communication, and are of opinion that his experiment is not such as to entitle him to the Society's first premium, inasmuch as the plants turned in are not the most succulent for the purpose of enriching the soil; also, because the experiment was extended only to a single year, without reference to the future improvement of the soil.

The committee are of opinion that a part of the field should have been manured in the usual way, in order to test with exactness, the comparative advantages of the two processes; but do not hesitate to express their satisfaction at the result of Mr Keely's experiment, as far as it went, and would recommend that a gratuity of ten dollars be awarded him for his valuable communication.

For the Committee,

Dec. 31, 1839.

JOSEPH KITTREDGE.

JOHN KEELY'S STATEMENT.

To the Committee of the Essex Agricultural Society on turning in Green Crops as a Manure:

GENTLEMEN—Perceiving that for several years no claim has been entered for premium on green crops, and deeming the subject one of great importance, I have concluded to present you with a statement on this subject. And I do it more with the hope that perhaps others may become inclined to try the efficacy of this mode of manuring, than on account of the great result abstractly considered.

The experiment was made on the same estate where the crop of rye was raised, on account of which I obtained the Society's premium, in 1832, but on a part which is very inferior in quality to the piece on which that crop was raised. It is indeed so poor that nothing but sorrel grows upon it spontaneously.

But although I have long been firmly convinced of the great efficacy and economy of green crops, yet I thought sorrel alone scarcely fit even to plough in for manure, until the following circumstance convinced me of the contrary.

At the close of June, 1837, the ground then being too wet to hoe, (as a storm was just clearing off,) I began to plough the piece of land, on which I intended to sow rye, principally, to prevent the sorrel from seeding. The next day was fine, and I left the remainder unploughed until September, when the whole was ploughed and sown together. The following spring a difference was seen on that part where the sorrel had been ploughed in, which difference became so striking that my neighbors saw it and inquired to know the reason. This determined me to try the experiment, which is here presented.

At the close of June, 1838, while the sorrel was yet in blossom, I ploughed it in immediately after a heavy rain, and sowed upon the furrow one bushel of buckwheat per acre. On the 6th and 7th of August immediately after a rain, and while the buckwheat was in blossom, that was also ploughed in. On the 13th September it was sowed with winter rye. The present season, the striking difference between this rye and that in the same neighborhood on land of better quality, was seen and remarked by several individuals, and some persons who have known the estate for more than forty years, say that they never before saw such heavy rye on that part. The whole piece contains nearly 2 1/2 acres; and it yielded 48 bushels of rye, of excellent quality, weighing 59 lbs. per bush-

el. I should remark that about one-third of an acre of this piece is so poor that no sorrel ever grew there; the buckwheat was very light, and of course the rye was also. I should judge that upon rather more than two acres the produce was twenty bushels per acre. The previous crop on the same piece in 1837, did not average quite six bushels per acre.

You will perceive that the whole extra expense of this experiment is one ploughing and one harrowing, and one bushel of buckwheat per acre, which would cost about three dollars and a half per acre, and the extra produce 14 bushels per acre.

Although this crop is not large compared with other crops upon rich land, yet for land of this poor quality, I consider it very large. Nor is this all. This crop was not obtained by extra expense, to force the land to yield more than it could continue to produce; it is only the first of a series of crops, which if continued by the same management, undoubtedly will, in a few years, double its fertility, instead of exhausting it; and especially if the stubble is ploughed in soon after the crop is harvested, for this with the weeds amongst it, will furnish a third green crop, and the scattering grain which would otherwise be lost, will then grow and very materially increase the first green crop the ensuing season.

You will allow me to remark that experience and close observation upon the management of green crops, have convinced me that three things, among others which may be more obvious, are essential to a successful result.—First, it is absolutely necessary that the plough used is of good construction. Second, that some method be devised to prostrate the crop before the plough, or it will not be covered. I use a wooden roller about four inches in diameter and sixteen inches long, fixed on the end of the plough beam in a frame temporarily put on for the purpose. Third, it is necessary that the land should be ploughed very soon after rain, while it is moist, or the plough will crowd the furrow instead of turning it handsomely. It will also be of considerable advantage to roll the land after each ploughing.

Very respectfully,

JOHN KEELY.

Haverhill, Sept. 24th, 1839.

THE SEASON.

The impression seems to be general that fruit trees from appearances, have never passed through a winter with less injury, and that the promise of an abundant yield was never stronger. The months of December and January were remarkable for the intensity of the cold. February and March were remarkable for the mildness of the temperature. April has been variable; sometimes frothing and sometimes sniling. The season however, must be regarded as early; and the opportunities for ploughing and the usual spring work were seldom more favorable. It is a little extraordinary, that in spite of all the complaints of hard times, labor commands a high price, and laborers in most cases make their own terms.

H. C.

IMPORTATION OF EGGS. The sloop A. M. P., Capt. Brightman, has regularly, for twentythree years, made twentyfive trips a year from Newport, Mass., to this port, during which period she has brought to our market, on an average, five hundred dozen of eggs each trip, making a total of 3,450,000, averaging twelve cents per dozen—amounting to thirtyfour thousand five hundred dollars! *Providence Jour.*

It is stated that there is corn enough in Alabama to last the inhabitants two years.

BRIGHTON MARKET.—MONDAY, April 20, 1840

Reported for the New England Farmer

At Market 290 Beef Cattle, 10 pairs Working Oxen, 15 Cows and Calves, 225 Sheep and 1040 Swine. About 200 Swine were at Market last week.

Prices.—Beef Cattle.—The prices obtained last week for a like quality were not sustained. First quality, \$6 50 a \$6 75 Second quality, \$6 00 a \$6 25. Third quality, &c. 25 a \$5 75.

Working Oxen.—Sales \$70, \$78, \$85, \$90, and \$105.

Cows and Calves.—Sales \$28, \$32, \$33, \$35, \$40, and \$42 50

Sheep—No sales effected

Pigs.—All sold. Lots to peddle at 4 1-2 a 4 5-8 for sows, and 5 1-2 a 5 5-8 for barrows. Large barrows 5 1-4. Large sows 4. At retail 5 to 6 1-2.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded Northern exposure, week ending April 19.

MISCELLANEOUS.

SINGULAR HISTORICAL INCIDENT.

The Essex (Salem) Register, of 9th inst., quotes from the Mayor's Address to the City Council, the following singular fact: "In the amount received for rents is included the sum of \$153 82, which was paid by the lessee of the small tract of ground at Winter Island, which has, for several years, been occupied as the site of a Powder Magazine. This tract, described in the old Town Records as 'a portion of the upland beach, and flats, at Obear's or Palmer's head,' was leased originally, to Richard Derby, for the term of *one thousand years* from March 1, 1756, by an indenture executed by the Selectmen, under the authority of a vote of the town, at the rate of a *shilling a year*. The rent appears to have been irregularly paid by the lessee and his successors, though it is all shown to have been collected. The present occupant, to relieve himself from the trouble of annual payments, as well as, perhaps, to place his title beyond the risk of contingency, proposed to pay in advance without discount, the amount that would become due for the unexpired term of nine hundred and seventeen years, viz, 917 shillings, or the sum above stated, in our present currency. The proposal was of course accepted, and it may serve for the amusement, as it must require the leisure of some idle arithmetician, to calculate the vast gain secured to the city by this apparently inconsiderable financial operation."

THE PLANT INSECT.

At a very late meeting of the London Zoological Society, a communication was read from Mr Mackey, of the British consulate at Maracibo, on a plant, called Projojoy in the country from which it is derived, and which attains the condition of a plant from the strange metamorphose of an insect. In the insect which was described, some of the legs have already changed into roots, and in that state it was presented to the contributor. It was announced that a similar insect had lately been discovered in North Carolina. When the creature assumes the form of an insect or animal, it is about an inch in length, and most resembles a wasp in appearance. After it has reached its full length it disappears under the surface of the ground and dies, soon after which, the two fore legs begin to sprout and vegetate, the shoots extending upwards, and the plants in a short time reach a height of six inches. The branches and the leaves are like trefoli, and at the extremities of the former there are buds which contain neither leaves nor flowers, but an insect, which as it grows falls to the ground, or remains on its parent plant feeding on the leaves till the plant is exhausted, when the insect returns to the earth, and the plant shoots forth again.

A DEFICIENCY OF EVIDENCE.—A son of Galen, who was very angry when any joke was passed on physicians, once defended himself from railery by saying—'I defy any person whom I ever attended, to accuse me of ignorance or neglect.' 'That you may do safely,' replied a wag; 'for you know, doctor, dead men tell no tales.'

"What I gives is nothing to nobody," as the miser said, when asked how much he contributed for charitable purposes.

WINSHIP'S NURSERIES,

BRIGHTON, MASS.

The proprietors of this Nursery are now ready to receive orders for their extensive assortment of Fruit and Ornamental Trees, Forst at Trees, Shrubs, Herbaceous Plants, Roses, Green House Plants, Vines, &c.

March 11.

FOR SALE OR TO LET.

A wooden two story house, with six acres of fertile land, situated in Medford, within half a mile of the village. Said house contains four rooms on the first floor and six chambers. The premises are plentifully supplied, with a variety of choice fruit trees, in a thrifty and bearing condition.

A portion of the land is a superior location for a shipyard. The above is a pleasant and desirable place for a country residence.

For terms inquire of JONATHAN BROOKS, near the premises, or WILLIAM BRIGHAM, No. 35 Court Street, Boston.

March 25.

SINA SILK WORMS EGGS.

The Eggs of the celebrated Sina silk Worm, now offered for sale, were raised in 1839 by M. Cuvillier Beauvais, superintendent of the experimental silk farm established near Paris, by the government of France. The Sina Silk Worm was introduced to France from China by Louis XVI in 1784, and has been proved by J. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously.

Just received, by the subscriber, from the Cultivator Beauvais, who is the only agent for their sale in France.

Each sheet contains an ounce and is signed 'Cuvillier Beauvais.' Price 5s.

Committee are authorised to distribute 2 vols. N. E. Farmer and 2 of Yankee Farmer.

COCOONS AND SILK.

To the person who shall raise and exhibit the largest quantity of cocoons, \$4

For the next greatest quantity, 3

For do do do 2

For every ounce of wrought silk raised and worked in the county, ten cents.

P. S.—Cloths, fancy articles, products of the dairy, cocoons and silks, articles of invention, fruits, vegetables, &c., must be deposited in the Town House before 9 o'clock, A. M. on the day of exhibition.

Articles manufactured out of Plymouth county not admissible.

PREMIUMS CLAIMABLE IN FUTURE YEARS.

To the person who shall on the first day of September, 1841, have the largest quantity of land in the best state of preparation for English mowing, which is now fresh meadow or swamp land, \$25

Second premium for the same object, 15

Third do do do 10

For the most accurate and satisfactory experiment in the application of manure, premium payable in 1842, 25

Applicants for this premium will be required to appropriate for the experiment, one acre and a half of land, as nearly of the same quality of soil as possible. On one half acre, ten loads of manure, or a larger quantity if preferred, must be spread on the sward; then let the whole field be ploughed, and on the next half acre the same quantity and quality of manure be spread on the furrow; let the whole field be afterwards harrowed and planted with Indian corn. Let every part of the field receive the same attention and culture, and the crop on each half acre be separately harvested and weighed. The second year the field must be sowed with some kind of spring grain and grass seed, and the crop as before measured or weighed. The third year will be grass, which must be cut and cured in the same manner on each half acre and separately weighed.

The three crops will probably shew which course is most effectual, to bury manure under the furrow or apply it to the surface. And the produce of the half acre not manured, will shew the benefits derived from manure.

Claims to the above premiums must be entered

with MORRILL ALLEN, of Pembroke, on or before the first of May, 1840.

For the most extensive forest of any sort of trees suitable for timber, raised from the seed, not less than 1000 trees to the acre, which shall be in the most flourishing condition and more than five years old, in September, 1845, \$50

Second premium for the same object, 30

Third do do do 20

Premiums not demanded within one year, will be considered as generously given to promote the objects of the Society.

On all premiums above five dollars awarded to gentlemen not members of the Society, the Treasurer is directed to make a deduction of 25 per cent., to increase the funds.

The Trustees will not consider themselves obliged by the terms of the above offers, to give a premium in any case, when it shall be evident there has been no competition, nor more than ordinary exertion.

All entries for premiums may be made by letters post paid. Letters not post paid, will not be considered.

By order of the Trustees,

MORRILL ALLEN.

Bridgewater, January, 1840.

For the N. E. Farmer.

SCIENCE FOR FARMERS—ORNITHOLOGY

MR COLMAN—The next science which we shall introduce as claiming the investigation of farmers, is that of Ornithology, or the science of birds; and surely, since we have the assurance that He who guides the planets in their courses—who causes the outgoings of the morning and the evening to rejoice—who, indeed “upholds, supports and governs all creation,” who gave goodly wing to the peacock, “hears the young ravens when they cry,” and notices the falling sparrow.—it cannot by any natural, moral, or theological pretence, be inconsistent for us who were created in our Maker's image and endowed with the noble faculties which we justly claim, to seek kind acquaintanceship with any of his works, especially a part of his creation which contributes so much to the varieties of our temperament as the feathered race.

That birds are subjects of much annoyance to farmers, is a fact too evident to call for particular investigation. They pull up his grains, devour his fruits, in short give exercise to the current of his feelings, which might otherwise flow more equally and agreeably in a thousand ways.

What can be more at variance with the even tenor of a man's spirits, when his cornfield has been planted with much care and watered by much “sweat of his brow,” than to hear a detestable crow, as if its heart was as black as its own plumage, cawing over the field where a golden harvest is expected as a remuneration for earnest labors, and anon seeing him alight under guard of a dozen of his fellows, whose habits of industry they prove in a manner no wise unworthy of human emulation, pulling it up as though it were wholly an affair of their own?

After all, the crow is not so much to blame for the invasions he makes upon the farmer's premises. The rich teasts which the golgotha where his dead animals are deposited, offer his craving stomach,

invite him to protract his stay through the long period of winter, and if his stores fail on the return of spring, who can wonder that if, after the liberality with which he has been fed in the inclement season he shall feel himself quite “at home,” when the season of brighter hopes returns? Yet for his familiarities there is ample remedy; for notwithstanding his courage in diving into the depths of air, and the apparent self-possession with which he enters upon our cornfields, he is still a coward, and is often frightened from his purposes by the most simple and inoffensive means; for he usually avoids “the man of straw,” and his ideas of ropes and halters are so odious, that if but simply a very small cord is extended around the premises where his mischievous visits are intrusive, he has the prudence to keep a proper distance. Their habits are also said to be rather favorable to the “striped pig” system, and that some farmers have availed themselves of this weakness of their nature, and brought them into fearful decay by soaking grains in “the ardent” and strewing them over their cornfields.

But with all his failings, the crow is not so bad a bird as he might be, neither is his heart so black as his plumage indicates; but in various ways proves himself an article of utility to the farmer, by waging war upon the worms and many other evil doers of insect royalty, which would gladly devour his labors. The same may be said of other birds which send forth their warbling notes to contribute to our cheerfulness, when nature puts on her rich attire. They may all of them appear to us as rather mischievous creatures, when in fact they are our efficient laborers, doing that for us in a short time in the destruction of our little insidious enemies, which we might never accomplish, or which if we did, it would be at an expense of time and labor which might be much more profitably and agreeably devoted to other objects. Why should we then complain if now and then a robin light upon our cherry trees, and pluck a portion of their rich fruit, to satisfy the longings of its own palate, when in fact one may be indebted to the same bird or some of its family, for the fruit we gather, if not from the same tree, from some other of Pomona's bowers? The same may be said of other birds; most if not all of them are useful to the farmer, and would be found to be so if he would study into their nature and habits. But we are too apt to be guided by first impressions, and for the want of this investigation, we conclude if we see a luckless bird light upon a grain field or a fruit tree, at a season when they may take from us a part of the spoil, that it is a thief, and belongs to a race of bandits, and that we should unhesitatingly wage war upon the whole posse. What an inconsistency! Man rebel against his laborers, when all the remuneration they ask is a part of their board—now and then a meal of the fruits they have so nobly and disinterestedly aided him in raising! “Alas for the weakness of poor human nature,” when it prompts us to rise in such fatal rebellions as the sacrifice of our friends—friends too, that teach us such powerful lessons of industry, economy, forbearance, constancy and many other virtues, as the birds of the air inculcate. Let us study their habits more effectually, and we shall be enabled to appreciate their worth more fully, and shall learn from them many more lessons of practical utility than they have yet taught to their most zealous amateurs and careful observers.

After all the powder and lead which has been wasted in attempts to annihilate the feathered race,

many of them yet prefer an abode where civilization should reign, to the deep-tangled shades of the forest. They still look up to man as their protector, and would read in his visage and conduct those lineaments of friendship which he was designed to exhibit. And to the praise of our race be it said, there are now many among us who consider it a sacrifice to rob a bird's nest, and an act of violence and guilt to take the life of its occupant; but on the contrary, they *invite* them to the groves and trees near their dwellings, feed them with their crumbs, and listen to the sweet music of their always accordant notes. Such kindnesses [can a bird be grateful?] they duly appreciate, by building their nests around our dwellings, that they may aid us by their services, in the destruction of annoying insects. But were their labors of no pecuniary benefit, the sweet music of their anthems, swelling forth in strains which know of no discord, in whose notes "the outgoings of the morning and the evening rejoice," would be ample remuneration for the few kernels of grain or little fruit they gather, and which we should always allow them to enjoy with the same feelings of pleasure that we spread an entertainment for a friend that loves us. Surely they would then teach us a lesson that man, aspiring man, is slow to learn of his fellow—a lesson of gratitude, of kindness, as they now do of long-suffering and forbearance.

But ornithology is not a wild romantic science, confining its subjects to trees and groves and mountains and clefts of the rock. It brings within its embrace the goose, of famed classic celebrity; the turkey, which in roguery and self-will, approaches so near to the perfection of man; with sir chazi-cleer, the factious *beau monde* of the farm yard, and head of its cackling seraglio; with all the varieties of plumed inhabitants which the poultry yard, roost and mud pond boast. These are animals of profit and taste worthy of his cultivation, as he would have his bacon seasoned with eggs, or his table enriched with choice luxuries. W. B.
Mount Oscola, March 2, 1840.

[From "Transactions of the Essex Agricultural Society."]

ON DISEASES OF ANIMALS.

For the last year or two a fatal distemper has prevailed among the cattle and animals of the county of Essex, and carried off many cows. Some individuals have lost half their entire stock, and some more. It has not been confined to neat cattle, but horses, hogs, and sheep have been affected. The disease has been very fatal,—one half of those affected, at least, have died, as is supposed; for it is difficult always to know all those that have been diseased. The disease lasts but four or five days, and sometimes the first knowledge of an animal's being diseased, it would be found dead in the yard. It is supposed to be contagious, by contact, as when it has appeared in a stock of cattle, many of the stock have fallen victims, and in two cases in Topsfield, where persons were engaged in taking off the hides of the animals that had died with the disorder, their arms swelled up and broke out in large boils, which ulcerated and formed a large tough black scab, some of them the bigness of a twenty-cent piece, and some smaller. Some (not very severe) constitutional symptoms manifested themselves. The sores were sometimes in healing, four to six weeks. After these cases of apparent infection appeared, the animals were buried without flaying, and with as little connexion as possible.

It is supposed that these two individuals were inoculated, as one of them in flaying, made a slight wound on his hand with the knife, and the other had a fracture of the skin. The disease was so rapid that little or nothing was attempted to be done by way of remedy. The first appearance of disorder was, when the cow came from the pasture at night she would give evidence of not filling herself as well as usual, and would give a less quantity of milk; would refuse the ordinary kinds of food, and eat but little of the more delicate and inviting, and in three or four days refuse all kinds and soon lie down and die, and some purging of blood would appear, as the last effort of nature.—Pain and distress were more particularly manifested in horses at the close of life, by frequent lying down and getting up, and by grunting and struggles. The disease was most prevalent in Topsfield and vicinity in July and August.

The disease is probably a murrain, such as we read of in the bible and ancient writings. *Epizooty* is a term bestowed upon malignant distempers among animals. It signifies a plague or murrain among animals. In the common acceptation of the term, murrain is limited to distempers among useful and domesticated animals, whereas *epizooty* comprehends those pestilential ravages to which the whole living creation is liable. In one of the plagues of Egypt, spoken of by Moses, is recognized a most destructive epizooty, extending to all domesticated animals. Other accounts are given in ancient history of malignant and contagious diseases among animals.

In modern history, more particular accounts are given of pestilential and eruptive diseases, resembling small pox and plague in men. By some, inoculation was tried and supposed to modify the disease and lessen its fatality. This, however, was thought might spread the disease where it did not before exist, and was therefore prohibited by government.

"In 1661, after a hot dry summer, a kind of phrensy spread among animals, especially horses, cattle and sheep; but was not known to be contagious. It was principally confined to northern climates;—one or more worms were found in the substance of the brain. Numbers of intestinal worms were found in an epizooty that prevailed in 1663, and were thought to be the cause of the distemper. Analogous symptoms, though not equally fatal, attacked almost the whole cattle in the Danish territory, in 1674.

"France was visited by an epizooty among the black cattle in 1682. The animal functions were uninterrupted until the attack, when sudden death ensued. This was accompanied by a gangrene of the tongue, which came away in pieces. Those who attended the cattle are said to have been infected by the disease and to have died. Its progress was regular, and marched with astonishing rapidity at the rate of twelve miles a day. Thus it spread from the frontiers of Italy to Poland. Between the years 1705 and 1711, a distemper called the *flying chancre* or *hubo*, which the latest authors denominate a real plague or murrain, was found to be making terrible ravages in Europe. It had been imported by a single ox, brought into the Venetian states from Hungary and Dalmatia; and it was thence disseminated throughout the Roman territory and the kingdom of Naples, sweeping away almost the whole cattle in its progress. It did not reach France till 1714; and in the same year, having been some time prevalent in Britain,

the most vigorous means to repress it were adopted by government. All the animals were ordered to be destroyed that were attacked with it, and buried deep in the earth, and a compensation allowed to those who thus lost their property. The violence of the disease did not last above three months, during which time the counties of Essex, Middlesex and Surrey lost 5-57 cattle. At this time it was observed that cows being brought to water to drink, many became giddy, fell down in convulsions, bled copiously at the mouth and nose and died. Other nations suffered more severely; Piedmont lost 70,000 cattle; Holland 300,000; and the full extent of the epizooty throughout Europe was estimated to have destroyed 1,500,000 animals. All these perished of the infection disseminated by the single diseased ox from Hungary. But the disease was marked by considerable distinctions in different countries, and some of its symptoms bore little resemblance in one place to what were seen in another."

In 1730, a contagious disease appeared among black cattle in Germany, and afterwards in France, which affected the tongues, was called a blain of the tongue, which degenerated into a cancerous ulcer, whereby the organ was almost totally destroyed. The commencement and termination of the disease was sometimes witnessed within 24 hours. A most destructive epizooty ravaged Europe for ten years from 1740. This disease was exhibited by shiverings, palpitations of the heart, difficult respiration, cough, coldness of the hoofs and horns, cessation of the natural evacuations: sometimes the animal fell down as if struck by apoplexy.—Eruptions covered those which survived the violence of the attack. It was evidently contagious, and the strongest precautions were adopted to repress the infection. Former experience had proved, in the history of an epizooty by Laneisi, that they could not be too strictly adopted; for certain drivers having brought their cattle to a fair in Italy, in the year 1713, a prohibition was issued against holding it, in order to prevent the dispersion of the cattle. However, the drivers rather than be disappointed of a market, conducted them privately to Rome, and sold at a low price. Immediately afterwards, a contagious distemper spread through the whole Roman territory, and destroyed 300,000 animals. Notwithstanding precautions were used, such as burying the diseased cattle, interdicting the sale of their flesh, untoward accidents happened, and contagion was disseminated by the skin. But at different places in France, guards were placed, to prevent any cattle from approaching them, whereby the stock was preserved in health, though the malady was making rapid advances in the surrounding country.

The Marquis de Courtioron instituted numerous experiments regarding this distemper, from which he concluded that it exhibited itself on the fourth day from infection, that the ninth was the crisis, and that the contagion could spread only from direct communication between two animals. In the course of the year 1746, a new remedy, inoculation, had been attempted at Brunswick, and in an epizooty which appeared in Holland, the same remedy was repeated in 1755, though with little success, and recommended by Dr Lagard in 1757. The distemper in the latter country was considered absolutely similar to small pox; and the infection was said to have been brought from Holland by two white calves of a favorite breed, or by two skins of diseased animals. Whatever was the

cause, many animals perished of it. Different epizootics appeared about the same time, among the cattle, horses, and reindeer of France, Austria, Finland and Lapland. Swine, dogs, and even poultry, are said to have been attacked by it. Russia did not escape, and if we can credit the relations given, the malady was propagated by the skin of a bear, even to the destruction of mankind. These epizootics were either perpetuated or renewed during the years immediately subsequent, and, if possible, raged more extensively among the various genera of animals. The horses of Switzerland, the cattle of other countries, sheep, and particularly lambs, were swept away in thousands.

In 1764, dogs were attacked throughout France, poultry in Spain, and the rest of the feathered tribes throughout Europe.

The milk of infected cows spread the contagion; for those animals supplied were covered with pustules; and people who suffered with it, in the same manner, experienced great difficulty in swallowing and burning heat in the throat.

For some years after this period, an epizooty raged among the black cattle of Holland, and carried off the whole cattle belonging to one district. Its attack was commenced all at once, by the animal becoming dull and rejecting drink. Fever and shivering, attended by a general prostration of strength, followed; the ears and horns grew cold, a cough became intermitting, a purulent matter was discharged from the nose, and an ichorous fluid from the eyes. The hide was puffed up, and a crackling like that of parchment, was heard on pressure. Some were attacked by diarrhoea—others by constipation, from the fourth to the sixth day of the disease, and they died from the second to the eleventh day after the commencement. The blood of the animal then proved thin; the intestines inflamed and putrid, the lungs gangrenous, the gall bladder always greatly enlarged, and many worms were found in the liver. The symptoms were generally the same; and Camper, who strictly watched the appearance, progress, and issue of the malady, pronounced it a contagious putrid fever. Animals once attacked were never liable to its recurrence, or at least very rarely; hence Camper, from that and other circumstances, concluded that to repress it, four principal objects are to be kept in view.

1. To endeavor to prevent the malady and abate its virulence.
2. To preserve the fluids from corruption.
3. To preserve the strength of the animal.
4. To cleanse the intestines immediately on the appearance of the disease.

There was no way of guarding against contagion, but by excluding diseased animals, and all substances by which infection might be communicated. He also conceived that inoculation was the most proper method of averting the malignity of the distemper: forty-six out of ninety-two infected animals were saved, and of cows that were not far advanced in gestation, three-fourths were saved. Inoculation was successfully practiced in Denmark; in the first three years of the experiment, less than a sixth of the infected animals died. Strong prejudices in England were opposed to it, lest it might introduce the disease where it did not before exist. Camper established several important points; such as, that the epizooty imparted by inoculation, was exactly similar to that communicated by natural infection; that it was of a much milder nature; as also that animals infected in this way, resisted both natural contagion and the consequences of inoculation. The malady proved extremely destructive in Hol-

land; of 283647 affected, 208,354 died. In 1771 the disease broke out in Picardy, by the introduction of a diseased cow, and after being subdued, appeared again in 1773 with redoubled violence. Numerous remedies were tried, but their inefficiency being proved, the extirpation of the malady was sought in the destruction of the animals by strangulation, without the effusion of blood, and their carcasses buried with their hides entire. Similar ordinances were promulgated in France, with their hides cut to pieces, to prevent traffic in them, and that all the fodder, litter, and whatever else which might communicate the contagion should be buried with them. By these and other prudent regulations, this, which was one of the epizootics best characterized in history, was repressed.

During the period that contagious distempers swept away the cattle of Europe, a malady, even more rapid in its progress, appeared in the West Indies. Its effects seem to have been more minutely traced in Guadeloupe, where it first attacked black cattle, then horses, and afterwards spread to men. Animals apparently well, in good condition, and feeding as usual, were suddenly seized with shivering fits, attended by convulsions in the spine and abdomen, which sometimes carried them off in an hour. Almost all the negroes who opened the dead bodies had boils on their arms, attended by much fever; and those feeding on their flesh, had like symptoms. Examples were given of several who actually died from infection. Something similar was witnessed in France, where persons skinning the animals died of the contagion, the effects of which were immediate.

Between the years 1780 and 1790, a pestilential disease prevailed among the cattle in the northern counties of Scotland, vulgarly denominated *hasty*, from the rapidity of its progress.

The Eastern parts of Asia were visited by a destructive epizooty among the horses, especially in 1804; and after the severity abated, in 1805 and 1806, it was renewed with uncommon virulence in 1807. In so far as we can learn, this disorder consisted of a sudden swelling, attended by shivering fits, an abscess formed most commonly in the head, and the animal died in twelve hours at furthest. But in many instances, its commencement and termination were infinitely more rapid, and death was known to ensue in half an hour. The malady was observed early at Ochotsk. Cattle, reindeer, and horses all suffered; and at last, a caravan, consisting of eighty, preserved only ten. The Russian Government of those distant regions, in order to repress the disease, ordered all the animals perishing of it, to be burnt; but before its nature was well understood, the Jakutchians, to whom horse flesh is grateful, unwilling to lose such a source of subsistence, fed on it. Most of those who had done so, died within a day or two; and a few lingered a fortnight. Those who escaped were attacked by severe swellings, in the upper lip and cheeks, which broke out and left great scars.

Besides these epizootics of which a general historical view has been given, others, extremely rapid in their progress and destructive in their effects, could be detailed, and their sources might admit of various conjectures. Most of those which attack the larger and more important animals, bear a strong resemblance to the plague among mankind. They have been traced, in some instances at least, to miasmata, which if not the origin of such a terrible malady, unquestionably foster its germs, and they are more destructive in all regions during

the same period that the plague is most fatal. Probably some animals are exclusively the victims of some epizootics, while others of different genera may escape unhurt; but it is to be doubted whether any races are totally exempt from them. Thus we are told that the fish of Lake Constance perished from a general mortality in 1732. We have seen many of the feathered tribes occasionally suffer, in different countries; infectious disorders frequently prevail among dogs; and a contagious distemper attacked the cats of Westphalia in 1682; while the same species were almost extirpated from the Ferroe Islands by an epizooty, in 1798. It is not an improbable theory that entire genera of animals, once inhabiting the surface of the earth, or the waters, are now extinct from contagious maladies.

In the first or second volume of the New England Farmer, mention is made of a contagious disease breaking out in a drove of cattle, brought in from the country. They were ordered back again by the authorities, and the one that died to be buried; but one individual wishing to save the hide, took it off, caught the distemper, and died. Two others tried out the tallow of another, and both it is related died.

In these remarks we have drawn largely from the Edinburgh Encyclopedia, where our readers are referred, under the article of Epizooty.

We have thought proper to add this supplement to our report, that the farmers in Essex may be on their guard another season. Although the distemper has appeared in several towns in different parts of the county, yet, it is feared, it has not yet exhausted itself, and may again return another season, when heat, drought, or moisture may favor it.

The small pox is now more prevalent than it has been for many years, in New England. The connexion between epizootics, plague and small pox, which has been hinted before, is another reason for watchfulness.

R. A. MERRIAM.

Topsheld, January, 1840.

From the Farmer's Monthly Visitor.

FENCES &c.

HON. ISAAC HILL.—Dear Sir—In my journeying through the New England States I have frequently been struck with the want of beauty and too often the want of durability and sufficiency of the walls and fences, enclosing and upon otherwise beautiful farms. In some parts the scarcity of stone, and in others the difficulty of procuring the common fencing materials, such as cedar rails, &c. is the common apology for the absence of a good, secure, and durable fence. There are many objections urged against hedges, with how much reason I leave others to decide. The doubtful nature of the experiment, however, and constant care supposed to be necessary to bring one to perfection, added to the risk of its ultimately providing a safe closure, deters many from setting it. Its beauty is certainly a strong inducement to give it a thorough trial. Hon. Barnabas Palmer of this town, has a beautiful hedge under way, with every prospect of complete success. In your June number (6) of the Visitor, he gave some information derived from sources entitled to great respect, in regard to the quality and proper cultivation of hedges. His hedge, which was set in May last, is of the Buckthorn variety, and was procured from the farm of E. H. Derby, Esq. of Salem, Mass. It is now something better than two feet high on an average,

and appears to be doing exceedingly well, with only three times hoeing since set, and bids fair to become a competent fence in four years or less. Mr Palmer gave the preference to the Buckthorn, from the representations of those better acquainted with it, that it is more hardy and rapid in growth than the other varieties, and from its possessing certain medicinal qualities, rendering it unpalatable to cattle, which would deter them from browsing it. Many prefer the Cockspur, or Delaware thorn to any other, by reason of its having a thorn on it, thus rendering any attempt to penetrate it less likely to succeed. I did not intend, however, to have said so much in regard to hedges, but to propose a substitute to such as may not feel inclined to try the hedge. There is a beautiful specimen of hedge around the marine Hospital at Chelsea, of the maple leaf Washington thorn, which appears well. The hedges around the garden of the Insane Hospital at Charlestown, are Hawthorn; but this plant is generally supposed to though its foliage is exceedingly beautiful; but it requires too much and careful attention to be profitable, and will not thrive well in our climate. I would recommend to those who feel curious in these matters, to visit and inspect them, should business or other circumstances call them to Boston.

In the interior of New York I frequently saw a species of wall or fence made of *stones and sods*, which was thought highly of there, and which I think might be profitably introduced among us. I will endeavor to describe it, and the process of making it. First a layer of stones from four to six inches high, say eighteen inches in width. On top of this is put a layer of sods, grass down, carefully filling up all the interstices in the stone beneath, then a layer of stone, then sod, thus alternately until your wall is at the desired height, when you cap it with sod. Grass seed is then sown on the top, and around the sides on the edges of the turf, which should come out "flush" and smooth with the stone. The following season the grass entirely covers and conceals the stone, and you have a most beautiful and solid wall. I would observe that the thickness of the wall, in order to prevent its settling, should diminish as you ascend; eight or ten inches width at the top being sufficient. The sods necessary for the wall, being generally, or for the most part, taken from the spot, is usually done so as to make a good drain, some four or five inches deep on each side of it. Fears may be entertained that this description of wall would not be secure from the effects of the frost. I was particular in my enquiries on this point, and was assured that no essential injury was perceived to arise from it. I saw many which had been built six to ten years, and they appeared solid and firm. You have very likely seen the batteries and redoubts thrown up in many places on our sea-coast, during the last war. There are many such on some of the islands in Portsmouth harbor; at Eastport, Me., Fort Sullivan was entirely surrounded with them; they were composed generally of bushes, slavings, &c., covered at the top and sides with turf. They have retained their shape, verdure, and solidity for years. In fact I apprehend there is but little danger of so great an expansion by frost as to destroy a wall such as I have described, especially after the grass roots become firmly united and knit together. This kind of wall may be built as cheap as rail fence. I have known it laid for thirtyseven and a half cents per rod. It appears nearly as handsome as hedge, and when built in the summer is in full perfection

the following year. This kind of wall can, perhaps, be better built, than any other in those neighborhoods, where there is a deficiency of large stones suitable for entire stone walls, and where a slaty quality of stone prevails.

In conversation with a friend lately, on the subject of walls and fencing, and the expense of building them, he informed me that having made it a subject of inquiry with a view of erecting a wall himself, he could not estimate the cost of good stone wall in this vicinity, at less than five dollars per rod; an item of expense which but few can afford, and which all would probably choose to avoid.

I am, dear sir,

Very respectfully, your friend, &c.

BENJA. F. EMERY.

From the Salem Observer.

PEACH TREE BORER.

Messrs Jees & Pease—As the season is now approaching to look over our peach trees, I send for your Observer a few hints upon their culture, for which I am in part indebted to Mr A. J. Downing, the intelligent Newburgh nurseryman.

"The greatest enemy to the peach tree in our vicinity is what is here called the borer. From ignorance of its habits and mode of proceeding, it has increased so much within the last ten years that the average life of the peach tree appears to be reduced to about five years duration." Among the numerous recommendations have been, boiling water applied to the roots, placing anthracite coal ashes around the trunk, &c. These are not effectual. The easiest and most certain method of ridding the peach tree of this disease, is to search out and destroy the worm itself, semi-annually.—Every spring and autumn remove the earth four or five inches deep, about the neck or stem of the tree. On laying bare the bark, if the tree is attacked by the worm, gum will be discovered. When this is the case, take your knife, and opening the bark, follow the channel made by the worm until (if it have not left the tree) you discover and destroy it. Remove the earth, and the wound caused by the worm (if it do not completely encircle the tree) will speedily heal over again. This is easily done, and if followed up in spring (April) and in the fall (October) will soon exterminate them from our gardens.

J. M. I.

TRANSPLANTING FRUIT TREES.

As the season has now arrived to set trees, (particularly peach trees—spring being, as we apprehend, preferable to the fall for stone fruits,) by your request, I have forwarded a few remarks relative to my method of re-setting fruit trees.

Transplanting trees seems a very simple process; all do not however practice it equally well. The land should be mellow, free from lumps and stones, and made fine; the hole for a tree an inch through at the butt should be 2 1-2 feet across, and from 10 to 15 inches deep. Care should be taken that the tree is not set deeper than it originally stood. Before setting, any bruised or broken root should be smoothly cut off with a sharp knife—fill in with your hand the fine soil all around the roots, placing all the fibres, &c. in as horizontal a direction as possible. When the hole is about half filled up, pour in 3 or 4 quarts of water, in order to settle the soil about the roots; when this has soaked down, fill up with soil; and upon no account pour

buckets of water upon the surface, which is sometimes done after the tree is transplanted, as it will often bake the earth so hard as to prevent the admission of air and dew.

J. M. I.

CULTIVATION OF THE TOMATO.

As the cultivation of this wholesome vegetable is much more attended to among us than formerly, and as there are many methods resorted to, in order to obtain fruit early, I have forwarded you a few hints on the subject.

First, force the plants in a hot bed,—transplant them when about four inches high in a light, well manured loamy soil,—(strong soil with green manure induces the plants to grow rank and produce their fruit late in the summer.) They do better and fruit earlier in a warm soil by raising them in the manner of potatoes, that is in hills, (one plant to a hill,) and when they begin to throw out laterals, place brush wood around the plants, that they may spread upon it, which brings the fruit near the ground, and will hasten its ripening.

J. M. I.

DISEASE OF HORSES, &c.—I see a great many cures for disorders in cattle and horses, in your Genesee Farmer. *The Ringbone* is a great plague to horses, which is easily cured. Take one oz. of camphor, one oz. of oil of spike, one oz. of hartshorn, and one oz. of spirits of turpentine—put these in a phial and shake it well;—when it is fit for use put it on the foot above the ring, and rub it with the finger till it comes to the skin. It will take a week to use it on one foot, which it will cure, be it ever so lame or long standing, but the ring will remain.

To cure Scours in cattle or horses: take the seed of the narrow leaf dock—(it is a yellow root)—and give them a handful of the seed in their feed. It will stop it immediately, be it ever so severe. Or take a tea-spoonful of pulverized red chalk, and give it to a beast, and it will cure.

I had a spring colt sick with the scours, and I made inquiries of several old people about it; they knew nothing for it; I took my own remedy. I took a handful of the dock seed and steeped it in the mother's milk, and poured about a gill down the throat, and it cured it at once.

A cure for the Blind Sleggers in a Horse.—When ever you perceive it bleed them well in the spur veins, and physic them well with tamarack, which will soon cure him. I am yours,

ALEXANDER M'DOUGALL.

Wampsville, August 26, 1839.

Labor Saving Soap—recipe for making.—Take 2 lbs. soda, 2 lbs. of yellow bar soap, and ten qts. of water; cut the soap in thin slices, and boil all together two hours, then strain it through a cloth—let it cool, and it is fit for use.

Directions for using.—Put the clothes in soak the night before you wash, and to every pail of water in which you boil them, add one pound of soap. They will need no rubbing; merely rinse them out, and they will be perfectly clean and white.

The recipe for making this soap have been sold at from \$5 to \$10, and the soap seven cents per pound; but can be manufactured for about two cts.—*Farmer's Cabinet.*

To make rancid butter sweet.—Melt and simmer it; then dip into it a crust of bread well toasted on both sides.—*Id.*

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, APRIL 29, 1840.

POULTRY.

We have much pleasure in presenting to our readers the reply of our friend Hunt to the queries put to him a few weeks since in the N. E. Farmer. They are full and satisfactory. We should be glad to hear again from our correspondent at Roxbury, who can, no doubt, if he will, give us some valuable suggestions from his experience. We published in our last the amount of eggs exported from Westport to New York market. The number of eggs and the amount received for them were enormous, and show that "many titles make a mickle."

"The capital invested in poultry and rabbits in Great Britain is estimated at £10,000,000 sterling." "When we look," says McQueen, "at the immense number of eggs brought from Ireland, (50 tons of eggs and 10 tons of live and dead poultry having been shipped from Dublin alone in one day,) and 60,000,000 eggs imported from France for London alone; and this immense number a trifle certainly to what are produced in this country, we shall cease to wonder at the large capital here stated to be invested in poultry of all kinds. The quantity of eggs imported into Liverpool from Ireland in 1832, was 4007 crates, value £81,940 sterling; which at 6d. per doz. gives 3,277,600 dozens, and the number 39,331,360. In 1833, the import had increased to 7,851 crates, or upwards of 70,000,000. The number imported into Glasgow from Ireland in 1835, by the custom house entries, was 19,321 crates, which at nine eggs to a pound, gives the number, 17,459,568.

The production and consumption of poultry, game, &c. in Great Britain and Ireland, may be judged of by the consumption of Paris, in 1822, of the following articles and animals, according to Count Chabrol—931,000 pigeons, 1,389,000 chickens, 549,000 turkeys, 328,000 geese, 131,000 partridges, 177,000 rabbits, 174,000 ducks."

This shows the magnitude of an interest which is deemed by most farmers of too trifling consideration to be worth making any calculation about. It is, without doubt, a proportionately great interest in this country; yet who in this aspect deems it worth attending to.

As to our good friend Hunt's pertinacity about his personal beauty, it will be seen that he struts about and crows as loud as any old rooster. Now we shall not dispute the point any farther with him, but quit the yard; and, as most people do who hear him, we agree to 'sign' it. C.

WYOMING, Penn., April 20, 1840.

To the Editor of the New England Farmer:

DEAR SIR—In reply to the inquiries in your paper of the 8th inst., I answer—

1. There is but one way to keep your roosters separate, and that is to have separate yards for them. A yard five feet by ten is large enough for a rooster and twelve hens.

2. I give my hens fresh raw or cooked, just as is convenient. When I could obtain it, I gave the liver, &c. of any animal, cut up into small pieces. One sheep pluck I found sufficient for nineteen hens and two roosters for seven days. Fat pork, boiled or raw, always sets the hen a singing—a sure precursor of laying.

3. A temperature of about *temperate* is best. This is generally obtained by a tight room with glass windows. I am satisfied, however, that a small stove in severe weather, would be of great service. I am preparing a house thus furnished.

4. Young chickens for the first week require a temper-

ature of from 75 to 80 deg. Far., and at night always about 80 deg. This last may be obtained after the chickens are over a week old, by a tight box, with a hole in one end, at the bottom. The heat of the bodies of the chickens will soon raise the temperature to the right degree. I observe here, that I found my opinion as to the degree of heat requisite for young chickens, on a actual experiment with the thermometer and the old hen, following nature as my guide: she is generally right.

5. I raised one hundred and fifty chickens in a room twenty-five feet long and seven feet wide; two feet high in front, and four feet high in rear. The roof was covered tight for the space of four feet; the remaining three feet and the front of the room was covered with slats just far enough apart to keep the chickens from getting out. The chickens were put into this, having a southern exposure, after they were about two weeks old, and kept there until they were well fledged. The tight box of course placed in the oven for them to sleep in. The three-feet-slat covering I had made so that I could remove it, to get into the room if necessary. A pan for water and for food, with the sleeping box, furnishes the room.

6. If you put one old hen in, she will kill all the chickens except her own.

7. Answered in 5.

8. You may take the young chickens as soon as they are a day old from the hen. It is best, however, to let them remain a day or two.

9. Answered in 5.

10. I gave my hens raw carrots. They would not eat them. They are fond of raw turnips cut up; also of rat baga. I suppose that any food they will eat is good for them.

11. The moulting varies. Hens in good condition moult in a shorter time than those which are poorer.

12. I have not been able to ascertain "the habitat" of the Creole. They are white with black spots all over, except the neck, which is perfectly white. Their tails are more fan-like or displayed during laying time, and their rumps present a fuller or more elevated appearance than other chickens. The ends of the tail feathers are generally blackish. They can be obtained about Philadelphia. The purest kind can be obtained in Buckingham, Bucks county, Pennsylvania. My good friend, Wm. H. Johnston, of that place, will cheerfully direct to such persons as have them. They are capital layers—poor setters.

13. Judge Barr, of Vincent Town, New Jersey, has the Booby hen, and the finest collection of poultry I have seen any where.—The long Backs county hens weighing so much, are the Malays. They are not good layers, and their eggs are very apt to have two yolks; of course do not hatch well.

With respect

THOS. P. HUNT.

N. B.—You were wrongly informed as to my teaching my children to believe me to be "the handsomest man," &c. I was not under that necessity. They believed it by *intuition*—and I insist upon it that that which is intuitively true, cannot be *demonstratively* false. Of course, I am not content to admit them, that your judgment is infallibly correct. All that I can admit is, *your* judgment is sincere; but my children say they have never seen a man as handsome as I am, nor do they believe that you have.

REVERSES IN TRADE.

At a sale of morus multicaulis on Saturday last in Boston, 1000 superior plants with good roots, were sold for ten dollars—one cent apiece. On Monday, a lot 5 ft. high brought two cents apiece, and a lot of 3 ft high, half a cent each. Two years ago and these same trees

would have found nimicks enough to have bought them at fifty cents or seventy-five cents a tree.—Our growers and sellers here do not understand matters. If they would put them into *royal* lands in New York or under *medical* care in Pennsylvania, with a few hampers of champagne, just to moisten the throats of the bidders, so that they could speak loud enough for the auctioneer to hear them, they would be likely to go off better. But it is rather dry work here. Two thousand of the Alpine likewise, were offered last week for seven dollars and a half.

Towards the many honest and industrious persons who have been beguiled into the mulberry tree speculation by fictitious sales, and gross impositions of various kinds, in many cases to their utter ruin, we feel a sincere commiseration; but with respect to many others, whose sole purpose was to enrich themselves at the expense of the unwary—who hesitated at no means to accomplish their unworthy ends, and who, emboldened and inflated by their early successes, ventured all their gains with a view to larger acquisitions, no one need lament that they have swamped their boat and gone to the bottom. It is only a just retribution.

Providence, however, will bring good out of evil. The introduction of the morus multicaulis must prove in the end an eminent blessing to the country. It is one of the most valuable plants that was ever grown; and if it should become acclimated, of which there are strong hopes, will be one of the main springs of a most valuable branch of domestic industry.

So far as the N. E. Farmer is concerned, we feel a peculiar satisfaction in that it cannot be charged upon us that we had any hand in encouraging this most extraordinary speculation, the multicaulis bubble, which has exploded, not sooner than we anticipated, and brought ruin and embarrassment upon hundreds and thousands of excellent people. Nor can it be said that we did not discourage it, much to the annoyance of some of our good friends, when we expressed our opinion that it was quite as wise to give fifty cents apiece for cabbage plants as for multicaulis plants; and in various other forms attempted to allay the popular fever. But what is the use of standing up before a hurricane? and what does a man gain, as Dr. Franklin remarks, who spits against the wind, but to spit in his own face? These trees are now almost as much below their actual value as they have been above it. They are fully worth all it costs to raise them. The silk culture must go on in the country, and conducted in a domestic way, will yield all reasonable profits. With these we ought to be satisfied. To this object the morus multicaulis will lend a most essential and valuable aid.

H. C.

OPPORTUNITY FOR EMIGRANTS

MR COLMAN—I have received a letter from a highly respectable gentleman in Fayette county, Virginia, making certain inquiries, which, as they may be interesting to some of our enterprising young farmers, who are disposed to emigrate, I know of no mode in which both they and the writer can be so well subserved, as by the publication of the following extract in the Farmer, if you should think that it may possibly be beneficial to any portion of our fellow citizens.

Yours, truly,

H. A. S. DEARBORN.

"I have a large tract of western Virginia land, on to which I removed with my family a few years since, and am trying to establish a farm. I have never owned slaves and do not wish to do so, if I can get on with white labor; I therefore should be glad to obtain the services of two moral, industrious young men, sons of farmers, and brought up to practical agriculture, from a term of not less than two years, on the terms of taking lands at the

expiration of their services, as their chief compensation. Say one hundred acres each year as the yearly compensation, or its equivalent, as they would want some pecuniary advances to clothe themselves, or articles furnished by me of good quality and fair price. The land to be of the average quality of my survey. I want men who are enterprising, and not too nice, in so wild and sparsely settled region. They must not expect the facilities or luxuries of an old garden spot like Massachusetts.

"As I have a large body of unsettled land, I would be glad to obtain some eight or ten families as settlers, and will give 50 acres to each family, provided they will purchase 150 more, at a fair price and on reasonable terms." My residence is on Pine Creek, which falls into the Great Kanawha.

Any person interested may have more particular information by inquiring of the subscriber at Boston.
April 26, 1840. HENRY COLMAN.

Northern pullet. { No. 1, 2, 3

MISCELLANEOUS.

Honest Poverty Rewarded.—A gentleman of New York arrived at the Tremont House a day or two ago, on his way to Lowell, and while in the city had occasion to exchange some money. He placed the bills in his vest pocket, and took the cars for Lowell. When he reached there he discovered that he had lost a five hundred dollar bill. The loss seemed irreparable, and he abandoned all hope of recovering the money. The gentleman returned from Lowell and was not a little surprised to learn that a Methodist clergyman, the Rev. T. C. Pierce, had been put in possession of the money by an honest orange seller, named Connell, at the Lowell depot, who had found it there the gentleman having dropped it while procuring a ticket for the cars. The first thing the gentleman did upon getting his money back, was to present Connell with fifty dollars, and he assured Connell besides, that if ever he was thrown out of employment, he would always find a friend ready to assist him. Such an instance of honesty in a poor man, is worthy of all commendation. It was fortunate for the owner that many who pass themselves off for gentlemen, were not the finders.—*Boston Atlas.*

Keeping Truth in the Dark.—A very good widow lady, who was looked up to by the congregation to which she belonged as an example of piety, contrived to bring her conscience to terms for one little indulgence. She loved porter—ay, dearly,—and one day just as she was receiving half a dozen bottles from the man who usually brought her the comforting beverage, she perceived (O, horror!) two of the grave elders of the church approach her door. She ran the man out the back way, and put the bottles under the bed. The weather was hot, and while conversing with her holy friends, pop went one of the corks.

"Dear me!" exclaimed the good lady, "there goes that bed cord! it snapped yesterday just the same way: I must have a new rope, that's sartin'." In a few moments pop went another, followed by the peculiar hiss of the escaping liquor. The bed-cord would not answer this time, but the good lady was not at a loss.

"Dear me!" says she, "that black cat of mine must be at some mischief there. Scat you torment!"

Another bottle popped off, and the porter came stealing out from under the bed curtains! This was the hardest case of all to get over—but our good old soul was yet 'on hand'

"O dear me!" said she, "I'd forgot—it's the yeast! Prudence! come here and take away these bottles of yeast!"—*Picayune.*

Freedom of the Press.—A Newfoundland paper, in speaking of the House of Assembly of that island, enlarges it in the following unequivocal language: "Take them all in all, from the Speaker downwards, we do not suppose that a greater set of low-lived and lawless scoundrels, as public men, can be found under the canopy of heaven."

Evading a tax.—A miser being asked why he had married a girl from his own kitchen, said the union gave him a double advantage: it saved him not only the expense of a wife but the tax on a servant.

WINSHIP'S NURSERIES,

BRIGHTON, MASS.

The proprietors of this Nursery are now ready to receive orders for their extensive assortment of Fruit and Ornamental Trees, Forst Trees, Shrubs, Herbaceous Plants, Roses, Green House Plants, Vines, &c.

Orders from a distance will be properly packed to go with safety to any part of the United States, and will be delivered in the city free of expense.

The Nursery grounds are five and a half miles from the city, by the Worcester Rail Road; cars stop three times a day. Orders by mail addressed to Messrs. WINSHIP, Brighton, Mass., will be promptly answered.

PEAR, PLUM, GRAPE VINES, &c.

2,000 Pear Trees, of the most approved kinds.
1,000 Plum Trees, of the most approved kinds and extra size—many of them have borne the past season.

500 Quince Trees,
3,000 Isabella and Catawba Grape Vines, from 6 to 15 feet high, most of them have borne fruit—Black Hamburg, Sweetwater, Pond's Seedling.

30,000 Giant Asparagus Roots,
5,000 Wilmot's Early Rhubarb or Pie Plant, lately introduced.

Also—a good assortment of Gooseberries, Roses, &c. of different kinds.
All orders left at this office, and at Gould & Howe's, Iron Store, 85 Panel Hall, or with the subscriber at Cambridgeport, will meet with immediate attention.

SAMUEL FOND,
Cambridgeport, Mass.

March 4.

SCIONS OF FRUIT TREES FOR SALE.

The collection of fruit cultivated at the Pomologic Garden consists of more than 100 varieties of the Apple, Pear, Plum, Cherry and Peach. Scions of all those which have been proved are offered to nurserymen and others—Gentlemen wishing to send collections of American fruits to their friends in Europe can be furnished with most of those of first rate quality. They are warranted true to their names, and are in all cases cut from fruit bearing trees.
Salem, January 25, 1840. ROBERT MANNING.

FRUIT AND ORNAMENTAL TREES.

JOSEPH BRECK & CO. offer for sale a great variety of Fruit and Ornamental Trees and Shrubs at Nursery prices, consisting of Apple, Pear, Peach, Plum, and Cherry of every variety.

Horse Chestnuts, Weeping Willows, Mountain Ash, Silver leaved Alder, Spruce, Fir, Larch and other Ornamental Trees.

Currants, Gooseberries, Raspberries, &c. Also—Roses, Honeysuckles, Altheas, Snowberries, Persian Lilacs, &c.

Orders carefully executed, and the trees well packed, in such a manner that they can be sent without injury to any part of the country.

March 11.

FOR SALE OR TO LET.

A wooden two story house, with six acres of fertile land, situated in Medford, within half a mile of the village. Said house contains four rooms on the first floor and six chambers. The premises are plentifully supplied, with a variety of choice fruit trees, in a thrifty and bearing condition.

A portion of the land is a superior location for a shipyard. The above is a pleasant and desirable place for a country residence.

For terms inquire of JONATHAN BROOKS, near the premises, or WILLIAM BRIGHAM, No. 35 Court Street, Boston.

March 25.

SILK WORM EGGS.

The Eggs of the celebrated Silkworm, now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The same silk worm was introduced to France from China by Louis XVI. in 1784, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Eodin, who is the only agent for their sale in France.

Each sheet contains an ounce and is signed "Camille Beauvais." Price \$8.

WILLIAM KENRICK, Newton.
Or apply to JOSEPH BRECK & CO.
March 25. epl

AGRICULTURAL AND HORTICULTURAL TOOLS.

Just received, at the New England Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, per Ship Chatham, from England, a splendid assortment of Agricultural and Horticultural Implements, viz.

100 dozen	Best Cast Steel Sickles.
50 "	do " Stout Cast Steel Error Hooks.
25 "	do " Breaking up Hoers.
5 "	do " Pruning Chisels with Saws.
20 "	do " pair Grass Shears.
25 "	do " pair Pruning Shears, with slides.
25 "	do " pair Ladies Ivory handle do. do.
25 "	do " pair Ladies Coco do. do.
5 "	do " Large Hedge Shears.
25 "	do " Wakefield's Pruning Shears, with slides.
50 "	do " Large Pruning Knives.
25 "	do " Budding do. do.
15 "	do " Cast Steel Edging do.
5 "	do " do " Hay do.
5 "	do " do " Garden Trowels.
20 "	do " Bill Hooks.
10 "	do " Furze Hooks.
10 "	do " Gentleman's Bright Bills.
5 "	do " Horticultural Hatchets.
50 "	do " Dutch Hoers.

April 1. JOSEPH BRECK & CO.

SILK WORM EGGS.

Just received, a few ounces of Silk Worm Eggs, from Smyrna, and to be of a superior variety. Price \$3 per ounce, clean seed. JOSEPH BRECK & CO.
April 1.

FOR SALE OR EXCHANGE.

A valuable farm in Harvard, County of Worcester, the well known Bromfield Place; an excellent dairy farm, well watered, the house spacious, fitted for two distinct families. The situation among the most pleasant to be found, especially for agriculture or High School. Bordering a part of the farm is a beautiful sheet of water, containing two islands belonging to the estate. Inquire of the Subscriber at South Natick.
March 4, 1840. I. H. T. BLANCHARD.

Green House Plants.

Green House Plants of every description furnished at short notice, and well boxed, so that they may be sent to any part of the country in safety.

March 11. JOSEPH BRECK & CO.

BOX FOR EDGINGS.

JOSEPH BRECK & CO. have for sale 500 yards of Box for Edgings, in prime order; price 3½ cents per yard; every yard will make two when reset.

Giant and Early Wilmot Rhubarb.

Roots of extra large size at 25 cents per root, for sale by JOSEPH BRECK & CO.

White Silesia Sugar Beet Seed.

100 lb. of the genuine White Silesia Sugar Beet Seed; the best variety for the production of Beet Sugar and warranted to be pure from mixture.

For sale by JOSEPH BRECK & CO. No. 52 North Market Street, Boston, March 4, 1840.

GARDEN MATS.

For sale at the New England Farmer, 100 dozen Garden Mats, of extra quality, for covering hot beds, &c.

Feb. 12. JOSEPH BRECK & CO.

BEAN POLES.

500 dozen of Bean and Dahlia Poles, for sale by MOSES FRENCH, Maine Wharf, Broad Street, near the bottom of Summer St.

April 15. 4t

ROHAN POTATOES.

For sale at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at \$4 per barrel, \$2 per bushel.

October 16 JOSEPH BRECK & CO.

Buckthorns.

Buckthorns for Hedges, for sale by JOSEPH BRECK & CO. from 20 to \$20 per thousand, according to size and age.
March 25.

THE NEW ENGLAND FARMER

Is published every Wednesday Evening, at \$2 per annum payable at the end of the year—but those who pay with us sixty days from the time of subscribing are entitled to a reduction of 50 cents.

TUTT, DENNETT AND CHISHOLM, PRINTERS,
17 CORNHILL, & FIG. ST. BOSTON.

N. E. FARMER.

For the New England Farmer.

ESSAY ON THE SILK CULTURE,

And New System of France and of Eastern Asia.

Silk is destined to become ere long, one of our most important agricultural productions. The great interests of our country and, its peculiar situation and circumstances, demand the change. Our immense importations of iron, of wine, of silk, and of manufactures, so far exceeding all our exports, have inflicted upon the country a large foreign debt; this being one of the main causes of all our troubles, and of the continual recurrence of disastrous times.

Hitherto the silk culture has been earnestly recommended by many of its strenuous friends, but only and exclusively as a profitable domestic occupation, and only on a small scale. I shall endeavor to prove by authentic testimony and conclusive evidence, that the silk culture, like most other agricultural operations, may also be carried on in large establishments, and on a great scale, with far superior profits.

One of the most celebrated of the English writers on the useful arts and manufactures, is Dr Andrew Ure; and on agriculture, one of the most distinguished is M. Puvis, president of the agricultural society of Ain, in France. The subject of silk having been fully investigated by both, both writers being especially of the latest day, and both having in their remarks a particular reference to France. In a great part of that country, the soil and climate being favorable, both authorities concur in stating, that the planting of the mulberry trees and the raising of silk worms, are in this day the most profitable of all agricultural pursuits.

During the last ten years we have imported more than \$41,000,000 of wines, \$118,000,000 of silks, and \$84,000,000 of iron. In all \$243,000,000, and all for articles which may be produced in abundance from our own soil.

Our excessive importations impoverish the country. In 1839 our exports of domestic productions were but \$97,000,000, while our imports from foreign countries were over \$170,000,000. Of this amount about \$30,000,000 may be exported, leaving a balance of over \$44,000,000, to be paid for in gold and silver.

It is the policy of Britain to raise, to make, and to sell all they possibly can to other nations; while from those other nations they will receive nothing in return which they themselves can either make or produce; all these being excluded from their ports, either by heavy duties or by prohibitions. Thus while we receive nothing from them which we cannot ourselves either make or produce by our own industry, and from our own soil, they will purchase little or nothing else from us in return, except only our cotton, our silver and our gold. This policy of theirs, while it enriches them, impoverishes us, and should be resisted on our part by remonstrance, or by the laws of retaliation, as opposed to those first

principles of reciprocal and "equal rights and free trade," for which we so earnestly and justly contend.

In England, first of all countries for its agriculture, yet owing to the coldness and humidity of their climate, they cannot raise silk, how muchsoever they consume. In Europe, they usually lose from 35 to 60 per cent. of their silkworms, while in China they often lose not one in a hundred. In America it is the same, and from the same causes.

China, the native country of the silkworm, possesses a peculiar climate and country—a perfect parallel to which is to be found in no other country but our own. The French missionaries who had resided previously in America, have borne testimony to this striking similitude and important fact at a very early day. The geographical position of both and of each country is similar and alike; each having its own vast ocean on the east. By these extraordinary circumstances and this remarkable coincidence, is the climate of each country modified and controlled. In the middle latitudes of these countries, the prevailing winds for a considerable part of the year being from the west and northwest, and coming over a great extent of land, are dry and salubrious; they always bring fair weather, and delightful and bright sunny days. These winds are the counter currents of those trade winds which blow so continually and in the contrary direction within the tropics.

In Europe, this peculiarly favorable position is reversed; the climate of that country being modified and controlled by an ocean lying on the west and on the north; and the prevailing or westerly winds, blowing as they do direct from the ocean, they carry from thence tempestuous storms of rain, with clouds of aqueous vapors, which dissolve the snows of winter: during a considerable portion of the year, the sun's bright rays with their cheering and soul-reviving influence, are not seen.

Serene skies and days of unusual brightness are the characteristics of our climate. With a pure atmosphere and an elevated temperature, the growth of the silkworms to maturity is rapid and wonderful. The mulberry from China, which is so eminently adapted to afford a succession of food for numerous crops in a season, is also of a rapid and prolonged growth. Those serene skies and continuous days of heat and of sunshine, are necessarily duly to ripen and to prepare the juices of the plant; yet in the valleys of our great northern rivers, in every interior vale and low and extended plain of the north, this mulberry is liable to suffer injury in its tops. In spring they rise up with a luxuriance of vegetation the most extraordinary. Such is our climate, those days of unusual brightness being alone all-sufficient fully to elaborate the juices of the leaf, as has been amply proved, thus converting them into the most healthy and nutritious food. Yet at Nonantum hill, and in an elevated and bleak situation, I have several trees of the name multicaulis, of considerable size and vigorous growth, which, unprotected, have braved the rigors of the last winters and remain uninjured to this day. It is not thus in every vale. At

Portsmouth, in Lower Virginia, and in latitude 37° 12, and where I often visited during the year 1839, I found this tree in its hardihood bearing resemblance to the oak.

Many oppose the introduction of the silk business into our own country, by perpetually reminding us of the low price of labor in Hindostan and other countries, and the high price of labor in our own. The same arguments, if arguments they may be called, will apply in a greater or less degree to almost every branch of industry which we pursue, either in manufactures or in agriculture, but least of all can they justly be applied to any of the productions of our agriculture—silk being especially an agricultural production.

Can the poor Hindoo compete with the anglo-Saxon? We have seen a vast country in India, with a population of a hundred millions, brought into subjection by conquest, and still held in bondage by an army of from one to two hundred thousand Britons; thus from 500 to 1000 Hindoos are held in abject submission by the power of each single anglo-Saxon, and in that proportion they still hold a vast empire. It is absurd to talk of competition between the American free people and such nations as these. In that country men perform those same labors which in ours are performed by animal power, or by horses and oxen.

The vast power of Britain has its foundation chiefly in their agriculture, in which they surpass all other nations; also in their mines of coal and iron. With these last, engines and machinery are formed which, applied to their commerce and manufactures, perform labors equivalent to 100,000,000 of hands. But in their agricultural operations, animal power is chiefly employed. According to a late distinguished statistical writer, the amount of human labor employed in agriculture in England, is 5,000,000 of all descriptions of persons; or equivalent only to 2,132,446 effective men power; while the power of horses and oxen, or the animal power which is so employed, is equivalent to 22,500,000 effective men power; or ten times as great as the human power so applied. But in America, the proportion of animal power employed in agriculture, is transcendantly great, and far exceeding any thing that is known in the old world.

In our mines of coal, in our rivers and never-failing streams, we have also the abundant water power, and exceeding that of any other country or nation. By aid of this power and our machinery, a girl will spin a quantity of cotton in a day which would require the labor of 500 girls by the old mode, or of 500 Hindoos. In old countries, where labor is cheap, cultivation is performed in a great measure by manual labor and the spade. In our own country, our lands being both fertile and cheap, and pasture being abundant, we are enabled cheaply to maintain the vast animal power; the plough being truly the American instrument, by aid of these we are enabled to cultivate those lands far cheaper than they can be cultivated in any of those countries where labor is cheap and land dear. The silkworms require the abundant food and pasture, all which we are thus enabled cheaply to provide.

our horses and oxen performing these labors of men in our agriculture, re enable us to cultivate those lands far cheaper than by any other mode.

I hail the progress of every improvement, whether in our own country or in whatever country found. First of all we shall inquire what has been done, and what now is doing in those countries where silk has long been cultivated, or from time immemorial;—those countries of Europe and of Asia especially, from whence so lately we derived all our knowledge of the precious insect and of the plant on which it feeds. We must visit those nations in all their improvements, as they have visited ours. At the experimental silk farm which was established near Paris about ten years since by the government of France, and under the superintendence of M. Camille Beauvais, a new system of managing the silkworms has been established, the results of which are alike sure, infallible and extraordinary. These results have very lately been published in that country by authority, and by the direction of the French Minister of Commerce and Agriculture. By this system, all the wants of the silkworm having been made known by new discoveries, and being now for the first time fully understood, losses from disease are no longer known: they complete their course quickly, or in from 22 to 25 days, with great economy of time, of labor, of food, and of all things else, and with augmented production. Already and previous to the year 1835, by his extraordinary management, had M. Beauvais succeeded in producing thirteen pounds of silk from the same number of silkworms, which in France usually produce but five pounds, and in Italy seven and a half pounds, and in India twenty pounds, and even in that cold climate he then expected soon to be able to produce an equal number of pounds. In the year 1837 was enabled to produce 185 pounds of cocoons from 2000 pounds of leaves, and from that same number of silkworms or 40,000, which, being of a size so superior, must have been more than sufficient for the production of 20 pounds of reeled silk.

In their native condition, the silkworms are exposed to dangers continually, either from furious storms or from devouring foes. When worms suffer from cold, they consume their food but slowly; or if fed only at long intervals, or only by day and never during the night, a large portion of their food becoming dry, is consequently wasted:—the worms suffer not only by hunger, but also by tormenting thirst; they suffer also doubly after fasting during a long night, from the voracity with which they devour their food in the morning.

When silkworms thus suffer, their labors are prolonged to a very late period of time, or from eight to eleven weeks, the cocoons thus produced, being of inferior size, the thread slender and feeble, liable to break in reeling, and consequently causing both trouble and waste; and it is agreed that those worms which thus linger, forming small cocoons, consume full as much food as those which form cocoons of large size. Even when forming their cocoons, if the silkworms suffer by cold, they suspend their labors, the silk in their stomachs becoming congealed. If neglected at this critical period, they enter at once the chrysalis state, leaving incomplete their cocoon or silken tomb.

The silkworm is a cold-blood insect, its temperature that of the atmosphere in which it breathes; its vital energies are wonderfully accelerated by heat and retarded by cold: 77° as now discovered, is its proper element, or that wherein it flourishes

to perfection, but a little more elevated during the first two or three days. In this elevated temperature, and in a pure atmosphere, it consumes its food rapidly, requiring feeding constantly, not only by day, but equally so during night. In this temperature it completes its course quickly or in from 22 to 24 days, when it begins its cocoon, which it finishes suddenly, working night and day continually during three days. The cocoons thus produced, being invariably very large, the filament substantial and strong, not liable to break in reeling, or to waste: less than nine pounds of cocoons of a superior size and quality being sufficient for a pound of reeled silk. The economy in regard to food, by this system of constant feeding being also very great.

According to the authority of the Chinese treatises, and also the high authority of M. Camille Beauvais, while the French have usually lost near fifty in an hundred of their silkworms, the Chinese hardly lose one in an hundred. This small loss in China is to be ascribed, in part, to their superior climate, so much resembling our own; in part also it may be ascribed to their rejecting in the first instance, and invariably, those few worms that hatch first; but principally their extraordinary success is ascribed to their subsequent treatment of the insects, and to the great attention which they bestow on them—to their constant and night feeding, as well as by day, and particularly to their modes contrived for the purposes of ventilation, and for the preservation of a high and suitable temperature.

At the government establishment or experimental silk farm near Montgeron, in the north of France, M. Camille Beauvais, the superintendent, has adopted with signal success, the more complete system of ventilation and of warming the apartments, invented by M. D'Arcet. By this system, a high temperature being at all times preserved, the silkworms are fed twentyfour times a day for three days, during the first age; eighteen times a day during the second age; twelve times a day during the third and fourth ages; eight times during the fifth or last and longest age, during which they eat many times more food than during all the previous ages. The most perfect cleanliness being at all times preserved as indispensable. In conjunction also with this high temperature and continued feeding, by night as well as by day, a certain degree of moisture or dampness is indispensable, since it is found that a drying heat has the effect not only to absorb suddenly all the moisture of the leaves, thus rendering them unfit for food, but it absorbs also the moisture from the lungs and bodies of the insects. With a temperature of 81 to 84° of Fahrenheit, a degree of moisture must be preserved equal to from 55 to 59° of Saussures' hygrometer. Without this suitable degree of moisture, a high temperature was found by M. Beauvais to be utterly destructive. The same destructive effect it is well known is produced on the human system from similar causes. By this system of management, he has also ascertained that the worms eat more, while the consumption of leaves is diminished, because they make much less litter and waste: the education being completed with a very great saving of time, and consequently economy in all things. So great was this saving, that in 1836, the whole process was completed in 21 days, while in a common temperature it lasts usually from 31 to 33 days.

I have stated as the results of his experiments in 1837, at 185 pounds of cocoons, the product of 40,000 silkworms, and but 2000 pounds of leaves—

cocoons of this superior size being sufficient to produce 20 pounds of reeled silk.

The honor of the introduction of this system to America, is justly due to Messrs Cheney, of Burlington, New Jersey. In 1830 they tried the system, but without the apparatus of M. D'Arcet, which it was impossible then to obtain. Their success being wonderful; in 24 days the silkworms finished feeding, the product being 178 pounds of cocoons of the largest size, or 225 to the pound, with the consumption of 2000 pounds of leaves, or in that proportion. They are now making preparations for a complete and perfect trial of the system in all its parts, during the present summer, and with the aid of D'Arcet's system of ventilation: the results of this system being the most sure and infallible. The synoptical table containing a complete development of this system, and published by the French Minister of Commerce and Agriculture, has been republished in America by them. In that table the temperature, as there designated, is preserved at 77° generally. Four of those original tables have during the last month, been sent to me from France.

In describing the outline of M. D'Arcet's system of ventilation and "salubrious cocoonery," we suppose an oblong building, with four ranges of hurdles. In the cellar of such a building, and at one end, a stove is placed, a little elevated. This stove may consist of a plain common box stove, or a plain sheet iron air tight stove, of Olmstead's or any other pattern, which is found to consume an incredibly small quantity of fuel. This stove is surrounded on all sides except the front, with rough masonry, from the bottom of the cellar to the floor above, leaving a narrow space or cavity on three sides of the stove, this being the air chamber:—within this air chamber or narrow space, the cold air entering at the bottom becomes heated, and rising to the height of the floor above and thence dividing into four main branches, it is carried by four main wooden tubes beneath the floor, also beneath the hurdles: it escapes upwards through the floor by square holes, at intervals of about 2-1/2 feet asunder—the first hole being an inch square, the size increases in arithmetical progression as it proceeds, because the current diminishes in velocity. In the garret are four corresponding wooden tubes. Into these all the impure air ascending, enters by similar apertures from beneath and through the ceiling. These tubes conduct the impure air thus drawn out, to the chimney. Here and near the chimney, is also a fan-wheel or blower, of four times the area of each of the wooden tubes. Air being a substance so extremely light and ethereal that a vast body may be suddenly set in motion by a small power. In hot, sultry, calm days, by motion of the fan, impure air is drawn out, while a steady current of air enters the apartment from the cellar beneath. This air may be cooled when required, by ice placed in the cavity or air chamber. Thus it is that during hot and sultry days, and days of excessive heat, in some parts of India, the apartments of the opulent are refreshed by cool breezes artificially produced, a man standing at the door with a vast fan.

It has been very lately stated by Dr Ure, that the five guinea fan of the Messrs Lillie and Fairbairns, operates to admiration. In some of those vast manufactories of Manchester, where its use has been introduced, the whole impure and unwholesome air is completely and suddenly expelled and driven out, its place being supplied by pure air,

The profits of the silk culture are identified in a great measure with the production of large and firm cocoons; such cocoons being usually composed of a strong fibre, not liable to break or cause trouble in reeling, or to waste: eight or nine pounds of such cocoons being sufficient to produce a pound of reeled silk; such being invariably the production of the full fed silkworms brought suddenly to maturity in the shortest possible space of time. A strict attention to cleanliness, with careful ventilation; an elevated temperature, with constant and regular feeding by night as well as day, being all that is required; the evolutions of the silkworm being wonderfully accelerated by heat and retarded by cold. In Madras, the silkworm passes through all its mutations in 13 days. The profit, in fine, depends on the production of the greatest possible amount of silk from the least possible amount of food, with the least possible amount both of labor and of time.

At the annual exhibition of the American Institute, of New York, in 1838, a premium was awarded to Mr Danforth, of Hartford, Ct., for the fine specimens of reeled silk which were then and there exhibited by him, the produce of one eighth of an acre of land: the trees and roots being small and of the growth of the preceding year, being planted in close order in May, and completely covered beneath the soil, produced of leaves at a single gathering, at the rate of 9312 pounds per acre in the first year, the cultivation being about the same as for corn; the silk raised and reeled by himself and family, none of whom had ever raised a silkworm or reeled before. He found that the "large or long crop silkworm" required but 90 pounds of leaves to produce a pound of reeled silk.

In December, in 1839, at the exhibition of the American Silk Society at the city of Washington, Mr Aaron Clapp, of Hartford, received the premium of the Society, for fifty pounds of fine reeled silk, which was raised by him from young trees of but a year's growth, which had been buried beneath the soil in May of that same year, on an acre and a quarter of land from a single gathering of the first year. By weighing all the leaves, he found that 80 pounds only were required for a pound of reeled silk. He states that Mr S. B. Goodwin, of Wethersfield, produced from a quarter of an acre of land, at the rate of 14,300 pounds of leaves from a single acre of ground in the first year.

Also, in December, 1839, at the exhibition of the American Silk Society at Washington, the Rev. Mr McLean, of Freehold, N. J., received the Society's premium of \$300 for twelve pounds of reeled silk, which was exhibited by him, this being the produce of one quarter of an acre of land, and of small trees and cuttings which had been buried beneath the soil in May of that same year. The produce being at the rate of 48 pounds of prime silk from an acre of land; the whole produce of the leaves being 2576 pounds, or at the rate of 10,306 pounds per acre. Although in this experiment very great credit is justly due to the Rev. Mr McLean for his highly meritorious exertions, yet as 214 or 215 pounds of leaves were used for the production of a pound of pure silk, it is evident that more than half the amount of food must have been wasted, as has been abundantly proved by the experiments of others. In that experiment the silkworms evidently suffered from cold during those cold storms, as fire was seldom used; also from hunger, being fed but seldom, and only by day, and never during the night. Hence they lingered gen-

erally from 28 to 36 or 49 days, and the cocoons were consequently small, or 300 to the pound, the thread of diminished size, liable to disproportionate waste in reeling, and requiring ten pounds and ten ounces for a pound of reeled silk. Mr McLean by accurate account found that his reeled silk cost him just \$2 25 a pound, the same being worth from \$1 50 to \$6 in Philadelphia; yet it is evident that by a properly regulated temperature and more constant attendance during 21 days, with the same amount of food, and from the same labor of cultivation and of gathering of the leaves, more than double the amount of silk would have been produced, or more than 100 pounds, with but little increase in the amount of labor, except only in the reeling. Other and experienced gentlemen have calculated the cost of raising silk at less than \$2 per pound, even by the usual modes of management, and on domestic establishments.

In a congenial soil and climate, the trees of the morus multicaulis will attain to the height of from 6 to 8 feet from the cuttings of a single eye, during the first summer, as I witnessed during my visits to Portsmouth, in lower Virginia, in the latitude of 37° 12', in 1830. At that place, a tree 6 feet in height has been found to yield three quarters of a pound of leaves at a single gathering in the first summer, and the trees will bear stripping twice in that same year, a few leaves only being left on the tips; more than 10,000 such trees finding room on an acre. In the second year, the growth being strong and from well furnished roots, they will bear stripping thrice or more.

Of the mulberry tree there are many valuable varieties. The mulberry is a deciduous tree in the temperate regions, but an evergreen tree within the tropics. In the high table lands of the Deccan, in India, six crops of silk are produced in the year. The trees will bear stripping six times, a few leaves only being invariably left on the tips: they burst forth again with extraordinary luxuriance. In other parts of India, twelve crops in a season are produced. In China also, several crops are produced in a year. The mulberries in all those countries being kept low like plantations of raspberries. This mode and no other is recommended, to raise the mulberry in hedges. In America, as far north as New England, two successive crops in a year have been obtained; and in the States of the South three and four crops may be produced in a year, from the same trees of the morus multicaulis or Chinese mulberry, which is of a rapid and prolonged growth. Young worms require young and immature leaves, tender and succulent; but in the more advanced and last stages of the silkworm, leaves full grown and more mature are the most suitable food.

In most agricultural pursuits and in manufactures, there is great saving both of labor, of time, and of all things else, when operations are managed on an extensive scale. Silk is by no means an exception to this general rule; as the system of M. Beauvais most fully proves: so also the Count Dandolo had taught before. That silk may be cultivated on every farm and domestic establishment, however small, is a truth now established beyond dispute. Those distinguished masters have also proved, that when skill and science have come in aid, the silk business may also be carried on to profit far greater in large establishments and on an extended scale. The result of the operations of the experimental silk farm, which was established by the government of France, as conducted by M. Beauvais, has lately been published by the French Minister of Commerce

and of Agriculture. These results shew that the number of days of labor does not increase in proportion to the number of silkworms; for while the labor necessary to rear a single ounce of silkworms' eggs, or about 40,000, requires 31 days, ten ounces require but 210 days, and 100 ounces but 1160 days of labor. In the first instance, a day's labor produces but six pounds of cocoons; in the second instance, a day's labor will produce nine pounds; but in the last, or where 100 ounces of eggs are raised, a day's labor will produce seventeen pounds of cocoons.

Hail, progress of improvement, all hail! How swift its speed! In all things how great, how wonderful, in this our day! In vain do those false men oppose,—those foes to the interests of the country and to its fame, who would paralyze its energies and its resources,—aliens, who would destroy its industry and exhaust it of all its treasures for the benefit of foreign nations,—those men, in fine, who have ever been the unceasing opponents of every improvement in every age,—in vain do they strive to obstruct its progress and to cause a retrograde, or to stop its march, which is onward and irresistible.

WILLIAM KENRICK.

Nonantum Hill, Newton, March 12, 1840.

BONE AS A MANURE.

The use of bone as a manure for crops, particularly the drilled or root crops, is rapidly increasing in this country, wherever the ground article can be procured, and it appears to justify all the reasonable expectations that have been formed respecting its application. Mills for grinding bones have been erected near Boston, New York and Troy, where the dust is sold by the barrel or bushel, and where tried has generally been highly approved. In all our cities or large villages, almost any desirable quantity of bones could be procured, were it of consequence to preserve or obtain them; and as the expense of a mill for grinding cannot, we think be great, would it not be well to have one at least in every place where a saving or sale of this material is practicable. Bones simply crushed are useful, and their effects are more durable than when made fine; but when applied in the form of dust, the effect is quicker and more sensible.

That bones should be an active manure when applied to plants, is evident from their composition. According to the analysis of that excellent chemist, Mr Hatchett, the component parts of bones are chiefly four—the earthy salts, fat, gelatine and cartilage. The earthy salts are three in number: 1st, phosphate of lime; 2d, carbonate of lime; 3d, sulphate of lime.

Experience in the use of bones has proved that the gelatine is the most valuable part of the bones, and this analysis proves, that of all bones those of man and the calf are most serviceable as manures. In England, the dust made from bones brought from the battle fields of Europe, has been most esteemed, and until that source of supply was exhausted, ship loads of them were imported annually for grinding. Boiling bones for the purpose of making portable soups by extracting the fat and gelatine, injures them for the purpose of agriculture, in proportion to the quantity extracted. Bones from soap makers when crushed, are little more than the salts of lime; and these, though very valuable on some soils, can be obtained cheaper other ways.—The average quantity of gelatine is not far from 1.16 of the bone.—*Genesee Far.*

[From 'Transactions of the Essex Agricultural Society.']

ON EXPERIMENTS ON MANURES.

To the Trustees of the Essex Agricultural Society:

GENTLEMEN.—The only claim to which the attention of the Committee on Experiments on Manures has been called, is that of Dr Andrew Nichols, of Danvers. His farm in Middleton was visited in July and September. Early in the spring he had caused unleached wood-ashes to be spread on low and cold soils, and the crops of grass gave evidence that the application was very favorable. It had produced a heavy burden of grass on land which otherwise would have had but a light and sour crop.

His corn was manured with a compost made of a small portion of animal manure, seventy bushels of ashes and meadow or peat mud. The soil is a sandy loam. The growth in July was luxuriant, and in September there was a handsome display of full-grown, well-filled ears, in the judgment of the Committee about fifty bushels to the acre. This in some circumstances would not be considered a large yield, but the soil is naturally light and for many years had not been well manured. The Committee were satisfied by the appearance of the crop, that this year the proper manure and good treatment had been applied, and that in ordinary seasons a compost of ashes, meadow mud and barn manure, will, on sandy and loamy soils produce a fair crop of corn. In the locality of Dr Nichols's farm, it would be difficult and expensive to procure animal manure in sufficient quantities to plant any considerable extent of land, and we know of no cheaper or better substitute.

The attention of the Committee was also directed to a piece of barley, on which a solution of potash and peat mud had been applied, and the quantity of straw and grain appeared to have been doubled by the operation. But the advantages of this application were still more apparent on a small portion of land on which onions had been sown.—Although it was not in proper till for such a crop, it produced at the rate of six hundred and forty bushels to the acre. On a small part of the land none of the solution had been used; here, the crop was very light, giving evidence that the superiority of the crop was owing to the novel application.

The subject is important to farmers. Manure is the capital on which they do business. And the man who teaches them how to obtain it at a reasonable rate and in sufficient quantities, does the public better service, than if he lectured the live long day on copper and silver mines, and amused the sleepy hours with golden dreams.

The Committee think Dr Nichols's experiment valuable, and his statement satisfactory; they recommend that it be published, and that the Society's premium of twenty dollars be awarded to him.

For the Committee,

DANIEL P. KING.

Danvers, Dec. 28, 1839.

DR A. NICHOLS'S STATEMENT.

To the Committee of the Essex Agricultural Society, on Manures.

Persuaded of the importance of the discoveries made by Dr Samuel L. Dana, of Lowell, and given to the world through the medium of the reports of Professor Hitchcock and Rev. H. Colman, to the Legislature of Massachusetts, concerning the food of vegetables, geine, and the abundance of it in

peat mud, in an insoluble state to be sure, and in that state not readily absorbed and digested by the roots of cultivated vegetables, but rendered soluble and very easily digestible by such plants by potash, wood-ashes, or other alkalis, among which is ammonia, one of the products of fermenting animal manures, I resolved last year to subject his theories to the test of experiment the present season. Accordingly I directed a quantity of black peat mud, procured by ditching for the purpose of draining and reclaiming an alder swamp, a part of which I had some years since brought into a state highly productive of the cultivated grasses, to be thrown into heaps. During the winter I also had collected in Salem, 2-2 bushels of unleached wood-ashes, at the cost of 121-2 cents per bushel. These were sent up to my farm, a part to be spread on my black soil grass lands, and a part to be mixed with mud for my tillage land. Two hundred bushels of these were spread on about six acres of such grass land while it was covered with ice, and frozen hard enough to be carted over without cutting it into ruts. These lands produced from one to two tons of good merchantable hay to the acre, nearly double the crop produced by the same lands last year. And one fact induces me to think, that being spread on the ice, as above mentioned, a portion of these ashes was washed away by the spring freshet. The fact from which I infer this, is, that a run below, over which the water coming from the meadow on which the largest part of these ashes were spread flows, produced more than double the quantity of hay, and that of a very superior quality to what had been ever known to grow on the same land before.

Seventy bushels of these ashes, together with a quantity not exceeding thirty bushels of mixed coal and wood ashes made by my kitchen and parlor fires were mixed with my barn manure, derived from one horse kept in stable the whole year, one other horse kept in stable during the winter months, one cow kept through the winter, and one pair of oxen employed almost daily on the road and in the woods, but fed in the barn one hundred days. This manure was never measured, but knowing how it was made, by the droppings and litter or bedding of these cattle, farmers can estimate the quantity with a good degree of correctness. These ashes and this manure were mixed with a sufficient quantity of the mud above mentioned by forking it over three times, to manure three acres of corn and potatoes, in hills four feet by about three feet apart, giving a good shovel full to the hill. More than two-thirds of this was grass land, which produced last year about half a ton of hay to the acre, broken up by the plough in April. The remainder was cropped last year without being well manured, with corn and potatoes. Gentlemen, you have seen the crop growing and matured, and I leave it to you to say whether or not the crop on this land would have been better had it been dressed with an equal quantity of pure, well rotted barn manure. For my own part I believe it would not, but that this experiment proves that peat mud thus managed, is equal if not superior, to the same quantity of any other substance in common use as a manure among us; which, if it be a fact, is a fact of immense value to the farmers of New England. By the knowledge and use of it, our comparatively barren soils may be made to equal or excel in productiveness the virgin prairies of the West. There were many hills in which the corn first planted was destroyed by worms. A part of these were suppli-

ed with the small Canada corn, a part with beans. The whole was several times cut down by frost. The produce was three hundred bushels of ears of sound corn, two tons of pumpkins and squashes, and some potatoes and beans. Dr Dana, in his letter to Mr Colman, dated Lowell, March 6, 1839, suggests the trial of a solution of geine as a manure. His directions for preparing it are as follows: "Boil one hundred pounds of dry pulverized peat with two and a half pounds of white ash, (an article imported from England,) containing 36.55 per cent. of pure soda, or its equivalent in pearl-ash or potash, in a potash kettle, with 130 gallons of water; boil for a few hours, let it settle, and dip off the clear liquor for use. Add the same quantity of alkali and water, boil and dip off as before. The dark colored brown solution contains about half an ounce per gallon of vegetable matter. It is to be applied by watering grain crops, grass lands, or any other way the farmer's quick wit will point out."

In the month of June I prepared a solution of geine, obtained not by boiling, but by steeping the mud as taken from the meadow, in a weak lye in tubs. I did not weigh the materials, being careful only to use more mud than the potash would render soluble. The portion was something like this: peat 100 lbs., potash 1 lbs., water 50 gallons; stirred occasionally for about a week, when the dark brown solution, described by Dr Dana, was dipped off and applied to some rows of corn, a portion of a piece of starved barley, and a bed of onions sown on land not well prepared for that crop. The corn was a portion of a piece manured as above mentioned. On this the benefit was not so obvious. The crop of barley on the portion watered was more than double the quantity both in straw and grain to that on other portions of the field, the soil and treatment of which was otherwise precisely similar.

The bed of onions which had been prepared by dressing it with a mixture of mud and ashes previous to the sowing of the seed, but which had not by harrowing been so completely pulverized, mixed and kneaded with the soil as the cultivators of this crop deem essential to success, consisted of three and a half square rods. The onions came up well, were well weeded, and about two bushels of fresh horse manure spread between the rows. In June, four rows were first watered with the solution of geine above described. In ten days the onions in these rows were nearly double the size of the others. All but six rows of the remainder were then watered. The growth of these soon outstripped the unwatered remainder.

Mr Henry Gould, who manages my farm on shares, and who conducted all the foregoing experiments, without thinking of the importance of leaving at least one row unwatered that we might better ascertain the true effect of this management, seeing the benefit to the parts thus watered, in about a week after treated the remainder in the same manner. The ends of some of the rows, however, which did not receive the watering, produced only very small onions, such as are usually thrown away as worthless by cultivators of this crop. This fact led me to believe that if the onions had not been watered with the solution of geine, not a single bushel of a good size would have been produced on the whole piece. At any rate it was peat or geine rendered soluble by alkali that produced this large crop.

The crop proved greater than our most sanguine

expectations. The onions were measured in the presence of the chairman of your committee, and making ample allowance for the tops which had not been stripped off, were adjudged equal to four bushels to the square rod, or at the rate of 610 bushels to the acre. In these experiments 7 lbs. of potash which cost 7 cts. a pound bought at the retail price, were used. Potash, although dearer than wood-ashes at 12 1-2 cents per bushel, is, I think, cheaper than the white ash mentioned by Dr Dana, and sufficiently cheap to make with meadow mud, a far cheaper manure than such as is in general used among our farmers. The experiment satisfies me that nothing better than potash and peat, can be used for most, if not all our cultivated vegetables, and the economy of watering with a solution of geine, such as are cultivated in rows, I think cannot be doubted. The reason why the corn was not very obviously benefited, I think, must have been that the portion of the roots to which it was applied, was already fully supplied with nutriment out of the same kind from the peat ashes and manure put in the hill at planting. For watering rows of onions or other vegetables, I should recommend that a cask be mounted on light wheels, so set that like the *drill* they may run each side of the row and drop the liquid manure through a small tap hole or tube from the cask, directly upon the young plants. For preparing the liquor, I should recommend a cistern about three feet deep and as large as the object may require, formed of plank and laid on a bed of clay and surrounded by the same, in the manner that tan vats are constructed; this should occupy a warm place, exposed to the sun, near water, and as near as these requisites permit to the tillage lands of the farm. In such a cistern, in warm weather, a solution of geine may be made in large quantities with little labor and without the expense of fuel, as the heat of the sun, is, I think, amply sufficient for the purpose.* If from further experiments it should be found economical to water grass lands and grain crops, a large cask or casks placed on wheels and drawn by oxen or horse power, the liquor from the casks being at pleasure let into a long narrow box perforated with numerous small holes which would spread the same over a strip of ground, some 6, 8, or 10 feet in breadth, as it is drawn over the field in the same manner as the streets in cities are watered in summer.

ANDREW NICHOLS.

I certify that I measured the piece of land mentioned in the foregoing statement, as planted with corn, on the 21st of September, 1839, and found the same to contain two acres, three quarters, thirtyone rods. JOHN W. PACEOR, *Surveyor*.

CABBAGE, AS FOOD FOR HOGS.

A gentleman remarked, in our hearing, a few days since, that cabbage was a valuable food for store hogs. The idea was new to us, and we inquired the manner of feeding. In reply, he gave us the following as the result of his experience, the last summer. Having a fine patch of plants, and observing the bottom leaves beginning to decay, he directed his farmer to procure a water-tight cask, and gather a bushel of the lower leaves from the cabbage plants, and deposit them in the barrel

with a handful of salt, and one quart of corn meal. On this was poured the contents of the kitchen swill-pail, and the whole was suffered to stand undisturbed for twentyfour hours, when the process was repeated, with the exception of the salt—and so, every day, until the cask was filled with a mass of wilted leaves, about six quarts of corn meal, potato peelings, crumbs of bread, &c., from the kitchen; all in a state of partial fermentation. He now commenced feeding it to the hogs, and they eat with greediness, leaving other food for this. They were evidently as fond of this kind of mush, as ever "Mylnkeer" was of *sour-kraut*.

While the hogs were consuming the contents of the first barrel, a second was in the course of being filled, and so alternately, till the stock of leaves was entirely exhausted, which was about four weeks.

This gentleman gave his opinion, that he could not have prepared any other kind of food for hogs, known to him, at double the expense, that would have produced results so decidedly beneficial. An increase of appetite, improvement in their general appearance, and better heart, was the result of this method. The cabbages, he thinks, were greatly improved by plucking the redundant foliage; and he intends to plant a large patch of cabbages, the coming season, more fully to test the advantages of this kind of feed for hogs. We invite him, and others who may "experiment" in the business, to give us the results, for publication.—*Farmer's Cab.*

APPLE ORCHARDS.

The orchards in the interior of New England have been sadly treated for the last half a dozen years. In the commendable zeal to make our population more temperate, war has been waged against the apple trees, and some of the finest orchards have been razed to the ground: in other cases the trees have been neglected and left a prey to caterpillars, canker worms and the browsing of cattle, or else from neglect of the friendly pruning knife, to divest them of suckers and diseased limbs, have gradually deteriorated both in quantity and quality of the fruit. Now if the consumption of cider had grown into entire disuse, all the apple trees that ever stood on the ground at any one time, would not be too many for the profitable use of the inhabitants of New England.

If apples, unfit to be eaten or used in various ways for the use of man, were produced in quantities, it is ascertained that they may be advantageously converted into food for brute animals—for swine, cattle and horses. But there is not a tree producing bad apples that may not by grafting, in the course of five or six years, be made to produce plentifully the best of fruit. The fruit does now, and will for years to come, bear a high price. In the vicinity of Boston, the venders go about among the farmers and pay readily, taking the apples from the fields, three dollars a barrel, containing little more than two bushels, for Baldwins. As far in the country as this place, good winter apples sell for two dollars the barrel. In the yard, we believe, of Mr Gould at Henniker, in the month of October; we saw two trees at a distance, on which were apples appearing to be the blue pearmain, which would measure eight or ten barrels each. Now what growth can be more profitable than the apple tree which in a single season shall yield twenty dollars?

The true method of making an apple or any other fruit orchard productive, is to cultivate and ma-

nure the ground as for any other crop. An orchard should be kept in almost constant tillth. Taken when young, the tree may be so constructed with the use of the pruning knife as to interfere very little with the use of the plough, and so that almost any vegetable crop may grow under and among the trees. On ground well cultivated, fruit trees will invariably grow larger and fairer.

If the prospect of raising an orchard to those in advanced life look discouraging, we say unto all such that the man who has strength to labor does not live who is too old to plant and rear a fruit orchard. With careful cultivation on rich ground in favorable positions, an apple orchard will grow up to bearing in less than half the time that it would if left to itself and exposed to the clipping of cattle and the inroads of destroying insects. We may plant a nursery, and in two years the young tree will be fit for budding by inoculation: in two years more it will be ready to transplant, and in two more the tree will begin to bear. An aged relative living on the premises where the editor was born, which premises long since our recollection had not more than two or three apple trees of any kind fit for eating, lately shewed us over the flourishing orchard, planted by his own hands on a few acres about the old mansion, which orchard has for the last fifteen or twenty years produced from one to five hundred barrels of grafted Baldwin and russet apples, paying the interest on this crop alone of from three to five hundred dollars an acre. The old gentleman plucked from a favorite tree apples which it had borne several years, the grafts of which were by him there placed when his wife, now deceased, told him it was probably too late for them ever to witness their bearing: yet, he informed us, she did live long enough to eat of the apples in successive seasons, and he had lived after her for several more years to eat of the same tree; and now, at the age of seventyseven years, being able not only to mount the ladder and pick his apples from the trees, but to take up his barrel of apples and place it in the cart by main strength; he is still likely to witness the annual production of fruit from the same tree ten, fifteen and by possibility twenty years longer.—*Farmer's Monthly Visitor*.

SEEDS.—The certainty and continuance of the vegetative power of seeds depend greatly on being fully ripe, well secured, and preserved from too much confinement, heat, and dampness. Some, however, lose their vegetative properties much sooner than others.

Parsnep, rhubarb, and other very thin and sealy seeds are not to be depended on the second year.

Beans, capsicum, carrot, cress, leek, nasturtium, okra, onion, salsify, scorzonera, and small herb seeds should not generally be trusted the third year.

Artichoke, asparagus, corn egg-plant, endive, feticus, lettuce, mustard, parsley, peas, skirret and spinach, often fail after the third year.

Broccoli, cauliflower, cabbage, celery, kale, radish, and turnip, will vegetate well four or five years.

Beet, cucumber, gourd, melon, pumpkin, and squash—also burnet, chervil, and sorrel, have been known to vegetate freely five to ten and more years.

Some seeds should not be sown the same season they are grown. There is too much of a tendency in biennials to go to seed; and in annuals to vines and unfruitfulness.

* Perhaps in an excavation in a peat meadow, which would fill with water spontaneously, a solution of geine might be still more cheaply obtained, by simply adding potash, ashes, &c. to the stagnant water.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, MAY 6, 1840.

FLORULA BOSTONIENSIS.—A Collection of Plants of Boston and its Vicinity, &c. By Jacob Bigelow, M. D. Published by Charles C. Little and James Brown.

This is the third edition of a work published some years since, and adapted to the present state of the science among us. We shall allow the author to speak for himself in the preface; for we could not say what he says so well as he has done it.

"The taste for botanical studies which for many years has prevailed in this quarter of the Union, may with some truth be said to have had its origin about the time of the publication of the first edition of this work. The principal use of a local Flora is, that it enables botanical inquirers to direct their attention chiefly to the objects with which they are most likely to meet in their researches about home, and saves them from the more extended labor of searching for the names of these objects through the pages of general works.

"Since the publication of the former editions of the *Florida Bostoniensis*, much progress has been made in the knowledge of the structure and relations of plants. A revolution appears to be taking place in regard more particularly to two things. Firstly, the terminology of the science has been greatly extended by the introduction of more precise and definite terms to express the numerous forms of vegetable organic structure. This is rendered necessary by the vast additions which are continually making to the catalogue of known plants, to distinguish and describe which, language itself is often at fault. Secondly, a preference among botanical writers greatly preponderates at the present day, in favor of the arrangement of plants by natural orders and systems, rather than by the artificial method of Linnaeus. To those who cultivate botany extensively as a science, there can be no question that the natural method is far more exact and satisfactory. On the other hand, to beginners in study, the artificial mode is more easy of comprehension, and is more readily made available for the first steps in the identification of plants."

The book is well printed, and will be duly valued by those interested in the science. Our regret is that it should not be accompanied by plates. There should in such a work have been given at least a few colored plates of some of the principal plants described. This would have increased the expense, but the class of readers who use the book would gladly pay the additional cost for the value which they would have added to the work.

We cannot too strongly express the satisfaction which we feel in observing the strong impulse with which the public mind is now setting towards the study of the natural sciences—botany, geology, mineralogy, chemistry, zoology and various popular branches of natural philosophy. They make the whole world, the inanimate as well as the animate, alive to man. The intelligent inquirer and student of nature is never less alone than when alone. All nature is full of religious instruction. Here is God's earliest revelation; and every thing discloses to the inquiring mind the wonders of his creation and providence. As to mere controversial theology, most of it—we say it with all due respect to the opinions of those much better informed—is a perfect waste of the mind. As to politics, who is the better in them for knowledge, or wisdom or truth? Here party and passion, not principle, regulate every thing. As to metaphysics, who cares to wander in their intricate mazes blindfold, in endless labyrinths lost; or go upon a Quixotic expedition and run a tilt with windmills? But every fact in the natural world is interesting, important, and instructive; and the deeper we dig into this mine, the more precious stones we throw out. Some of our wisemen, the people who belong to the family of the Knowalls, speak with disdain of the study of nature in its minute departments,

and laugh at gathering daisies and running after butterflies. If such conceit deserved notice, we would throw it back upon them. But we say that the man who can pluck the humblest flower that springs out of the earth, or gather the smallest shell that is thrown upon the ocean's shore, or inspect the minutest insect that the microscope can bring within its ken, and not see in them with profound amazement, delight, and adoration, the infinite skill, wisdom and benevolence of the Creator, is sadly deficient in the highest qualities of the mind and heart.

Education cannot, in respect to the young, too much busy itself with these branches of knowledge. The child taught to know, to study, and to recognise every object in nature which comes in his way, will find in the world a continual "feast of reason and flow of soul"—will be inspired with an indomitable thirst for knowledge; will never be at a loss for recreation and for consolation; and will in a high and spiritual sense, "have meat to eat which others know not of." H. C.

A MANUAL, or AN EASY METHOD of Managing Bees in the most profitable manner to their owner, with infallible rules to prevent their destruction by the moth. By John M. Weeks, West Farms, Salisbury, Vt. New edition, revised and enlarged.

This book has been recently republished by Messrs Weeks, Jordan & Co., of this city. It is a capital little volume, and condenses much useful matter in a very small compass. We have had several hives of bees at different times, but cannot boast much of success in their management. This did not arise from neglect, but from ignorance of the best treatment of them, and from ill-constructed hives. This little book furnishes the most full and satisfactory information on the subjects on which it treats; and does it in a simple, concise, and perfectly intelligible manner. There is added at the end a series of questions, with references to different parts of the book, which are well adapted to test the reader's knowledge and understanding of what he has been over. Mr Weeks professes to give a perfect remedy against the bee-moth, which has proved so destructive to the bees, and so discouraging to the bee raisers. It certainly promises to be effectual and supplies a great desideratum. Mr Weeks' hive, of which we spoke not long since, is an admirable construction, built as then remarked, not upon the assassin and piratical principles, but upon the principle of give and take; and live and let live.

Mr Weeks discourages the practice of giving the bees a large room in the house or out buildings. Several establishments of this kind have come under our observation; but, in the majority of cases they have proved failures. We understand it to be Mr W.'s opinion that bees requires occasionally to warm or be colonized, when the young are sent out to provide for themselves, whereas if they all remain at home constantly with the old folks, and are continually marrying and intermarrying within, there is a tendency, not unobserved, we believe in other races of animals, to deteriorate, or as the phrase is to run out. We are not responsible for Mr Weeks' philosophy in the case; and we know no one better entitled to speak with authority than a man, who, with so much intelligent observation and success, has devoted so much time to the habits of this little, but most industrious and useful animal. The bee and the silk-worm, they put us quite to shame! H. C.

PROGRESS OF TEMPERANCE.

Twentyfive years ago, and within the compass of a pretty extensive acquaintance, we knew of not more than two farmers, who were not in the habit of giving ardent spirit freely to their hired men; and considered its use

indispensable. The measure then taken was to inquire what extra wages should be paid to the laborer to induce him to abstain entirely from the use of ardent spirit; and many were unwilling to come into such an agreement upon any terms. The next step in the progress was for the hired men, when they applied for employment to commend themselves by stating that they did not use any ardent spirit. Now no man makes any stipulation about it. The farmer gives none; and he gives no increase of wages. The hired man expects none; and in many cases so far from making any stipulation, he would be surprised if any thing should be said by his employer on the subject. He feels that his own character is in danger, if he should use it, or express any complaint at being denied it. This shows an immense gain to the cause of Temperance; and we can say with as much truth as pleasure, that of the hundreds of farmers whom we have visited in our explorations in different parts of the Commonwealth, not one farmer in fifty permits a drop of ardent spirits to come on to his premises. What greater blessing can come from heaven than is such an improvement in public sentiment and public morals, indicated by such facts. H. C.

ERRATA IN THE TRANSACTIONS OF THE ESSEX AGRICULTURAL SOCIETY.

We are requested to make some corrections in this valuable pamphlet which are deemed material. On page 38th, line tenth from top, the *no* is to be omitted. In the 12th line of the same page for 166 lbs., you must read one pound.

These errors occur in a most valuable paper by Dr. Nichols, of Danvers on the subject of manures, which we give to our readers in this number.

It may seem extraordinary to those not familiar with these matters, that such errors should occur and escape an earlier detection. But such persons know very little of the various passages which the author has to make before he presents his offering to the public. Sometimes his own manuscript is not plain. Then the compositor may err; or the proof reader may err; or the proof corrector may fail in his duty; or the letters may drop out of the form after all is done. As to proof readers and compositors, the poor author must make up his mind in the beginning, that they may be very acute and clever fellows out of the office, yet as proof readers and compositors they do not know any thing, and it is not to be expected that they should know any thing beyond seeing that all the ems, and ens, and points, and leads are in the right place. We confess it is mortifying enough to be made to say what you did not intend to say; and especially to be made to use a negative when we mean an affirmative. We sympathise with the Doctor in this case. Plague take the printers, we say! no longer ago than last week, instead of saying three full grown patterns, they made us say three full grown patterns; after all, it might have been much worse—or so might have been put in a much more inconvenient place, as for example had a certain lady of our acquaintance a few years since have put in a negative instead of an affirmative, certainly our friend the Doctor would have had much more cause to complain than if so had been thrust in without reason upon every page of his communication. We cannot say who is responsible for these errors, but we know who ought to *Foot* the bill. H. C.

SODA.—A few ounces of soda will soften a hoghead of the hardest water. It is greatly superior to either pot or pearlsh giving a delicate whiteness to the linen, without the slightest injury, and it never, unless excess is used, in the least affects the hands.

Massachusetts Horticultural Society.
PARTHULAR NOTICE.

THE COMMITTEE ON FLOWERS are respectfully requested to meet, at the Rooms of the Massachusetts Horticultural Society, 23 Tremont Row, on Saturday next, 9th May; a punctual attendance is desirable as business of importance will be brought before the Committee.

Per order,

May 2d, 1840. S. WALKER, Chairman.

The Report of the Committee of the Massachusetts Horticultural Society, offering premiums on Fruit for 1840, was received too late for insertion this week. It shall appear in our next.

Third letter from Hon. William Foster has been received and will appear next week.

BRIGHTON MARKET.—MONDAY, May 1, 1840.

Reported for the New England Farmer

At Market 125 Beef Cattle, 10 Cows and Calves, 150 Sheep and 600 Swine.

40 Beef Cattle and all the Sheep were reported last week.

PRICES.—Beef Cattle.—Nearly all the Beef Cattle were purchased Friday and Saturday; about thirty only were for sale this morning, consequently, sales were effected at an unusual advance. A few brought as high as \$7.50. We shall omit the prices generally until the market shall have become more settled.

Cows and Calves.—A few sales noticed. \$35, \$30, \$33, and \$35.

Sheep.—Prices not made public.

Swine.—Lots to peddle 4 3-4 for sows, and 5 3-4 for barrows. At retail from 5 to 7.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Gardens of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending May 3.

May, 1840.	7 A.M.	12 M.	5 P.M.	Wind.

MISCELLANEOUS.

Statistics of the Jewish nation.—The statistics of the Jewish population are among the most singular circumstances of this most singular of all people.—Under all their calamities and dispersions, they seem to have remained at nearly the same amount as in the days of David and Solomon, never much more in prosperity—never much less after ages of suffering. Nothing like this has occurred in the history of any other race; Europe in general having doubled its population within the last hundred years; and England nearly tripled hers within the last half century—the population of America being still more rapid; and the world crowded in a constantly increasing ratio, yet the Jews seem to stand still in this vast and general movement. The population of Judea in its most palmy days, did not probably exceed, if it reached, four millions. The numbers who entered Palestine from the wilderness were evidently not much more than three millions—and their census, according to the German statistics, which are generally considered to be exact, is now nearly the same as that of the people under Moses—about three millions. They are thus distributed:—In Europe 1,960,000, of which about 658,000 are in Poland and Russia, and 453,000 are in Austria. In Asia, 738,000, of which 300,000 are in Asiatic Turkey. In Africa, 504,000, of which 304,000 are in Morocco. In America, North and South, 5,700. If we add to these about 15,000 Samaritans, the calculation in round numbers will be about 3,181,000. This was the report in 1835—the numbers probably remain the same.—*Blackwood.*

The Jews' Love of Judea.—The most interesting circumstance which presents itself to my mind, in recalling what I saw of the Hebrew nation of the East, is the universal diffusion of the love, the undying love of the Jews for their own Judea, the Canaan of their fathers. Who could see, without emotion, thousands of poor Israelites, who from the remotest parts of Europe have made their way, by long and weary pilgrimage—through privations incalculable, and sufferings without end—often shoeless and almost clotheless—friendless, penniless, that they might see the city of David, and lay their bones in the bosom of Jerusalem. What multitudes are there among them who have sold their last possession—having gathered together their little, their insufficient all—and have started, marching towards the rising sun, from the Vistula, the Dnieper, and the Danube, on a journey as long as perilous. How many have perished, exhausted, on their way! How many have sunk in sight of the Mount of Olives! and how many have closed their eyes in peace and blessedness when the privilege has been vouchsafed to them of treading within the walls of Salem!—*Dr Bowring.*

"My Mother learned me to work."—Such was the remark of one of our Boston matrons, who had graced the first circle of society, whose husband was reputed to be rich, but who in the great commercial pressure of '37 had, in common with many others of his class, all the profits of years swept away. "My mother learned me to work"—and her face looked as happy in her cheap lodgings, as ever it did when surrounded by the paraphernalia of luxury and pride. Such a wife is a treasure;—but what would she have been, had not her mother learned her to work?—*Boston Times.*

Don't sleep with your Grandmother—transferring of vital powers.—A not uncommon cause of the loss of vital powers is the young sleeping with the aged. The fact, however explained, has long been remarked, and it is well known to every unprejudiced observer. But it has been most unaccountably overlooked in medicine. I have, on several occasions, met with the counterpart of the following case:—I was a few years since consulted about a pale, sickly, and thin boy, of about five or six years. He appeared to have no specific ailment, but there was a slow and remarkable decline of flesh and strength, and of the energy of all the functions, which his mother very aptly termed a gradual blight. After inquiring into the history of the case, it came out that he had been a robust and plethoric child up to his third year, when his grandmother, a very aged person, took him to sleep with her; that he soon after lost his good looks; and he had continued to decline ever since, notwithstanding medicinal treatment. I directed him to sleep apart from the aged parent, and prescribed change of air, &c. The recovery was rapid. It is not with children only that debility is induced by this mode of abstracting vital power. Those in good health should never sleep with sickly persons.

Consolation of Deism.—M. Trochin, Voltaire's physician, told some friends of his, that on his last attendance upon this celebrated writer, a few hours before his death, he heard him cry out in great agitation, "I die abandoned by God and man." "I wished from my heart," added M. Trochin, "that all those persons, who had been seduced by Voltaire's writings, had been witnesses of his death."

Coal in England.—Her coal is eighteen hundred feet below the surface of the earth. As late as the thirteenth century, coal was prohibited by royal proclamation from being burned in London, because it was a public nuisance! Now, the quantity used in that city annually, is not less than 2,560,000 tons for fuel, and 1,230,000 tons for gas.

FOR SALE OR TO LET.

A wooden two-story house, with six acres of fertile land, situated in Medford, within half a mile of the village. Said house contains four rooms on the first floor and six chambers. The premises are plentifully supplied, with a variety of choice fruit trees, in a thrifty and bearing condition.

A portion of the land is a superior location for a sheep-yard. The above is a pleasant and desirable place for a country residence.

For terms inquire of JONATHAN BROOKS, near the premises, or WILLIAM BRIGHAM, No. 35 Court Street, Boston.

March 25.

SINA SILK WORMS EGGS.

The Eggs of the celebrated Sina Silk Worm, now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The Sina Silk Worm was introduced to France from China by Louis XVI. in 1754, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France. Each sheet contains an ounce and is signed "Camille Beauvais." Price \$8.

Or apply to WILLIAM KENRICK, Newton.
Or apply to JOSEPH BRECK & CO.
March 25.

BROUSSA MULBERRY SEED.

We have recently received 50 lbs. fresh Broussa Mulberry Seed, which we offer by the ounce or pound.
March 25. JOSEPH BRECK & CO.

SCIENCE FOR FARMERS.

The eye was unquestionably formed for seeing, its location being placed in the most prominent part of the human frame, as well as the one most convenient to effect the purpose of its formation; and, also, the security with which it is guarded from danger, goes strongly to substantiate this fact. Its utter uselessness for all purposes, unless, indeed, it be as the fountain from which we pour our tears, or the windows through which we betray the emotions of the soul, is another wherefore of its utility or looking about, and its perfect adaptation for taking up objects and transferring their impression to the soul, where their qualities are appreciated, their beauties admired, and their deformities traced out, are proofs positive of the design of its creation.

The earth is admirably fitted up to please the eye and through that to delight the soul. Its rivulets, streams and majestic rivers,—its lakes, seas and oceans, whereon man goes in ships and does business on the deep,—its fertile intervals, broad plains, gently swelling hills and mountains with their craggy cliffs, towering far towards the sky,—its vegetable productions, the lichen that attaches itself to the rock, which was once, perhaps, worn smooth by the sports of our childhood; the tall old oaks that adorn the grove, the meadow and the mountain, giving beautiful variety to the scenery by their flowers, fruit and foliage; the many and wonderful links that make up the chain of animal creation, from the mote that holds kindred with nothingness, to the highest and most sagacious class of living things,—all these, aside from matters of general utility, were designed to convey pleasure to the mind, through the agency of the eye, and were they any of them to become extinct, there would be a hapless void in the mass of things. How fortunate that we cannot annihilate them. These things were made for the comfort and pleasure of man. He might have existed had there been no mountains or seas. He might have been endowed with a nature to exist independently of rivers and plains, and trees and fruits, and the endless variety of flowers—of insects and birds, in whose melody, “the outgoings of the morning and the evening rejoice;” and of the beast of the field. But they were made for man, and in testimony of their utility their Creator pronounced them good.

There are many other things connected with man's comfort and happiness which have not been done for him. In fact, every thing in connexion with the earth, evinces its Maker's wisdom in the creation, and all appears as though he had labored for man in doing that for him which his own efforts cannot accomplish. To us it remains to effect the minor changes necessary to rendering earth the abode of beauty and enjoyment. Hence it remains for us to clear away forests, build up the old waste places, open fountains, plant orchards, erect buildings, and a thousand other things, the importance of

which are more and more deeply felt as man advances in a state of civilization and refinement, and in just proportion with their progression, we see the beautiful harmony of order and tasteful arrangement developing themselves in all his labors. And how can these be effected without science regulates his plans? How can his territory be divided into convenient and beautiful fields, unless geometry draws the lines? How can the strong and beautiful walls which are to establish these divisions with unerring certainty, receive the impressions of durability, unless the law regulating the proportions of the two surfaces to the height and the material used in building, he carried into effect?

The employments of the Farmer certainly make large demands on the science of mathematics in many and various forms for their perfect accomplishment. We might as well enter into detail of all his labors as to attempt to enumerate the “thousand and one” ways in which necessity requires their aid, in proportion as he would do all things well. And as very near akin to them, may be urged the importance of the art of *drawing*, by which models may be taken at home and abroad of such improvements in all things relating to his profession as the advancements of the age may suggest.

Farms should always be laid out and buildings erected with regard to *beauty* as well as utility. The earth, at least that part of it originally assigned to man as his abode, was a *garden*, and undoubtedly a well-regulated one; arranged with taste and order. Every man's farm should be a garden *now*—all laid out in the most systematic, scientific manner. In laying out fields, reference must be made to the qualities of soil and surface. Straight fences and square fields are in most cases preferable, yet there may be instances where curves are to be made in fences, and the parallelogram and triangle, and for aught we know, the hexagon, are to be the proper forms. Now if circumstances invite to the formation of fields in manner nearly resembling either of these, or any other shape, good taste, economy in fencing, and every other consideration that we have thought of, would require that the best plan should be adopted. The science which teaches men to make economical fences, by savings in distance, instructs also in planting trees, disposing of rows in cornfields, and indeed in every work of men's hands where lines and distance are to be regarded.

The proper arrangement and location of buildings, is an object of utmost importance to all who bear the expense of their erection; and how often in passing through the country, do we find them of forms and in situations that would make Cincinnatus himself weep for their occupants, if he were to take a view of their localities and construction. It is not for us to lay plans for our fellow farmers in these affairs: we would only suggest the propriety of their making *themselves* sufficiently acquainted with the science of architecture, to enable them to draw their own plans and manage their own affairs in such a manner, as that posterity, into whose hands they must eventually pass, if built in the thorough manner they should be, may “rise up and

call them blessed,” instead of considering the work of their hands an incumbrance left to them, for which there can be no remedy and in which very little comfort or convenience can be found.

Farmers' buildings, like those of other men, should be built with reference to *convenience*, and they may be in all cases, and at the same time a proper regard be paid to their *appearance*. The house should always be placed (we say) at a respectable distance from the highway, and the larger the structure, the greater the distance required, for what can indicate a want of thought more perfectly than a large house standing on the borders of the universal territory, with a little cramped yard, or perhaps none at all between it and the public's empire? How much more *livable* is a residence thrown at a distance from the more penetrating gaze of the public, and sheltered by a beautiful park. This style of doing things we are aware, may meet the censure of many farmers, who estimate the value of their labors by the dollars and cents received, as an *unprofitable* way of doing things. But in this, ye calculating sirs, ye are mistaken. Keep the account of debt and credit with your lands, and you will find the plot before your door by far the most profitable of your domains. Maximize it then, not by the random process of guess work, but by a liberal application of *science carried into practice*, in giving it due proportions and arranging its fixtures in the most agreeable way, and be assured you will not only find your minds *liberalised* by the process, but your *enjoyment* will be greatly increased and your “value received” also. Other buildings should likewise, be perfected by the application of science with art in their arrangement and location, not only because a correct way of doing things, is that which is most agreeable to the *eye*, but also because it is most convenient and useful to those who are concerned in them. W. B.

Mount Osceola, April 30, 1840.

For the New England Farmer.

ON IRRIGATION AND MANAGEMENT OF WATER.

Boston, 3d May, 1840.

REV. MR COLMAN—Sir—Please to accept my thanks for your report containing the remarks on agriculture in England, by Mr Webster and Mr Silliman. I am much pleased to find that my own remarks are in accordance with the opinions of these distinguished citizens; and I am encouraged by this accordance to offer a few more observations on the modes of supplying and using water.

In my preceding letter, it was my principal object to draw attention to the constituent and creative powers of water and air; and had I known that this fact, (long since familiar to men of science,) had been presented to our farmers under the auspices of such names as those above, I might have omitted burthening your columns with my own speculations.

In every science it is necessary to have some

fundamental truth as a point of departure—a sure test to which we may always refer to prove all ulterior deductions. Water, air, light and heat, then, it is admitted, constitute the great chemical lever, by which the vegetable kingdom is raised, and the inert earth is the fulcrum on which it acts.

As far back as I can remember, irrigation has been practised in our country, although not so commonly as in Europe. The English mode described by Mr Webster, I have often seen in this State, where springs were at command. The use of a copious spring for this purpose, by General Hull, on his farm in Newton, gave rise to a suit between him and a manufacturing company, who complained against this use of the water, as it passed through his farm, contending that it diminished the power of the mill. The suit was decided against agriculture, but on what principles, I must leave profounder jurists to determine. If the great and commendable temperance reform had then been in operation, the mill company might have added to their complaint that the General drank too much of the water as it passed over his land. I can find no where in the code Justinian or the code Napoleon, any inhibition against the use of water for irrigation, in its passage over the successive farms. Perhaps when the importance of the agricultural interest becomes better understood, and the creative power of water better known, our intelligent legislators from the country will settle this question by statute.

In the conclusion of my last letter, in your paper of the 2d April, my allusion to the mode of retaining water on high grounds, for irrigation or other purposes, was not so clear as I could wish. I was absent, you are aware, and could not examine the proof. There are few farms which have not some place where water may be stopped and retained for future use. Some natural cavities, with a little labor, could be converted into ponds. Many narrow gorges between neighboring hills, may be made into reservoirs, by a short dam; and in both cases, if the earth be of gravel or sand, and too loose to hold water, it may be puddled with clay, or it will in a short time become impervious, by the natural sediment. These artificial reservoirs will be kept always full by the rain alone, provided they have the wash of a small quantity of land more elevated; and then they may be used for the irrigation of all lower lands, for supplying aqueducts, or even for watering cattle, and thus save the labor and waste of driving cattle over productive grass land to reach some distant spring. In Europe, where there is the smallest spring it is used to create artificial fish ponds, and in passing from one pond to the next, it is made to irrigate the intervening ground; and I never heard that the owner of the lower pond or ground instituted suits against his neighbor above, for using the water.

The *Noria* (wrongly spelt in my last letter *Norice*), may be used with economy, where much water is wanted from a well for cattle, or in case of a great drought, perhaps, for a garden. The *Hydraulic Ram*, which requires a small waterfall, I shall describe, as soon as I have time to draw you a diagram, on which a mechanic could execute it. But the *Syphon*, to which I alluded in my last letter, requires some further notice. I am somewhat proud of this application of that old instrument, for I never read or heard of its being used for agricultural purposes before I proposed it in France, more than forty years ago.

Let us now suppose that you have a sloping field

to the south, quite dry, which you would convert into a meadow; and there be on the opposite declivity of the hill, at some thirty or forty feet below the summit, a copious spring. It may be too far to carry the water round the hill from this spring, or you may not own the land over which it must pass to get round. (This was my case in France.) Now the process is simply this. Dig a reservoir about the spring. If it be a quick spring the reservoir need not be large; make a trench over the hill for the syphon to lie in. The trench need be only deep enough to be clear of the frost, excepting at the summit of the hill, and there only in case it be necessary to reduce the elevation to thirty feet above the reservoir; for the syphon will not draw beyond that elevation. The arm of the syphon, or crane, which enters the reservoir, is the short arm; the other arm, on the opposite side of the hill, must be a foot or two longer. Now to put this crane in operation, instead of drawing it by the breath, as usual, which would be impossible, both ends must be stopped—the end of the short arm being under water near the bottom of the reservoir,—then a hole must be made in the highest part of the syphon, if it be of wood, or if of metal, a short arm, three or four inches long, soldered in that place, through which hole or arm the syphon is to be filled with water by a tunnel. When so filled, and corked, forcing the cork down upon the water as much as possible, the stoppers may be taken out of both ends of the syphon at the same time, and it will continue to run as long as there is any water in the reservoir. Now, to avoid the necessity of renewing this operation, if the water should be exhausted, there must be a cock at the end of the long arm, or the diameter of the opening there must be calculated to take no more water than the spring will constantly supply: then it will run forever, or so long as the aqueduct remains sound. In performing this operation, it is necessary to guard against the retention of air in any part of the syphon: therefore, where any considerable portion of it runs over a plain, undulations must be avoided—otherwise, the air would be confined in the summits of these undulations, and could not escape, having the water on both sides, and filling the whole bore of the syphon.

If it be desirable to bring water from a well, a pond, or a river, at a considerable distance over a plain, or irregular ground, where there shall be no greater elevation on the route than thirty feet, this may be done with the syphon; and cannot be done otherwise, without digging a trench the whole distance, as deep as the water is at the source, at its lowest depth. This process was described in my last letter, in the case of Mr Chapman's wells in Charlestown. The receiving well or reservoir at the place where the water is wanted, must be a little deeper than the lowest surface of the water at the place from whence it is to be drawn; and the arm of the syphon longest, in the *home* reservoir; the water then will remain in that reservoir on the same level as in the river, pond, or other source. It will be seen that by this process, an abundant supply of good water may be had so near the surface as to be dipped out, in many cases; and in such cases, with no other reservoir than a sunken tub. It is also apparent that an inexhaustible supply of water so easily had, would authorise other attempts to use it for watering gardens, or even level fields, on a large scale, in very dry seasons.

The syphon may be used to drain swamps or ponds, where a lower point is not too distant, and

where the intervening ground is of rock, or too high to drain them in the usual way, by a ditch.—Some swamps may be drained even without an lower place to take off the water, provided a very loose soil can be found by digging wells in the neighborhood, and placing therein the long end of a syphon, communicating with the swamp. Finally, the syphon may be used to transport water from one stream to another, running in an opposite direction, when it is desired to increase one of them for manufacturing purposes: the syphon in such cases may be made large enough to take all the water out of one of the sources.

It should be remembered that, although a pump be a very ingenious contrivance, and well suited for a house or stable, it should not be used, where labor is high, for purposes which require a great consumption of water. The ingenuity of my countrymen will devise various modes of raising water a few feet; and they will always find, that the simplest is the best mode.

To return for a moment to that great hydraulic apparatus which draws water from the air, viz. the woods, I would ask our oldest inhabitants of this country, whether they do not remember many swamps, ponds, springs and brooks, in former times, which do not now exist? If so, I call this fact as a witness in favor of keeping good that source, as long as possible, by leaving wood on our hills. The diminution of wood lands, must be the cause of the diminution of water alluded to; and it is quite possible that some of our good mill powers will cease to be so, at no distant period.

The water retained on high grounds and in the gorges of the hills, as recommended in the beginning of this article, will be taken up in part by the surrounding woods, and contribute to their growth. And being arrested and conducted in channels for irrigation, it will then cease to run down in torrents carrying away, in its course, the soil and sometimes enriching rich meadows with sand or gravel.

In that part of France where I lived, there was much rain, and places where there was too much water, like those noticed in England, by Mr Webster; and the French have been in the habit of getting rid of this superfluous water in a way somewhat similar to that described by Mr Webster, but better suited to our stony country. They dig trenches sufficiently deep to be out of the way of the plough, and lay loose stones in them, and after covering these stones with brush and stubble, replace the earth, and drain the land without loss of any part of it.

I believe that many of our bogs may be raised and turned into rich meadows, so as to pay well for the labor, where stone, gravel, or sand is near. For example, ditch this land in the dry season with ditches six feet wide, and twelve feet apart; then fill these ditches with stones, gravel or sand, in the winter, when the cattle and the men have little to do. It will be easy carting over the level ice in these ditches, when the stone, &c. may remain an fall in when the thaw comes. I would not, however, advise any great outlay of money for such works, but merely to use them as a savings bank to receive the odds and ends of leisure hours.

I shall resume some of the subjects heretofore noticed rather too hastily, for practical effect, an endeavor to recollect a few of the modes of husbandry which may seem to differ from our own; so that practical farmers may make such use of them as they may please. It is quite possible that many tell old stories, as old men are apt to do; fo

am quite ignorant of American husbandry, know little of any other, and shall not, as I never have, consult books on the subject. I shall throw out y crude notions as they occur; and if you print em, sir, I shall conclude that you consider them outh the ink, and that is what they cost me—for y time is of no value.

Your ob't serv't,

WM. FOSTER.

N. B.—Should any one wish to try the syphon, described above I will with pleasure give any farther information wanted, or even direct the work, if be in the way of my rambles.

From 'Transactions of the Essex Agricultural Society.'

ON MILCH COWS AND HEIFERS.

The Committee on Milch Cows and Heifers, beg ave to offer the following report :

A larger number of entries have been made this ear than we have ever before seen. Seven cows id ten heifers were in the pens, offered for premi- n, and several others, which did not come within e rules of the Society. In respect to quality as ell as number, the improvement was very con- sicious, there being at the show last year but one w, and some ordinary heifers, all of second quali- ; whereas the present year, both cows and heif- were of superior quality, in beauty and excel- nce. The cow offered by Mr Caldwell, of By- old, particularly attracted the attention of the ommittee and the public; but as she did not come ithin the rules of the Society, we should not be arranted in awarding a premium. The cow offer- ed by Mr Ebenezer Upton, of Danvers, was con- sidered an extra cow.

Among the ten heifers offered, only one was in ilk; the others were yearlings. They were all omsing, and gave evidence of the increasing in- terest in the community, in raising a better kind of ock, than has been heretofore manifested. The eately enhanced value of all kinds of stock for a y years past, seems to have given an impetus to e farmers, and induced them to bestow more par- ticular attention to the subject; they seem to have en more careful to select the best for raising, in- ead of selling the best to the butcher. Fifty ollars for a cow, till within a year or two, has been ought to be a very great price. But within two ars, double, and in some instances three times at sum, has been paid for cows in the county of ssex, and the income has warranted the expendi- re. If good cows are worth fifty dollars, and su- rior cows from that to two hundred, as in one stance mentioned by the agricultural commission- ; they certainly will repay the farmer for bestow- ing his best attention in selecting and very nice re in raising young stock. Of course when ws command such prices, corresponding good eatment will be bestowed upon them in feed- ng and providing for them; and we cannot doubt for moment, but the farmer is always fully remun- ed, for the good care he may give to his stock, and specially to his cows. We believe that if some tention is given to have cows always supplied ith green succulent food, the trouble and expense ill be fully reimbursed, in the increased quantity nd improved quality of the milk which they will eld. It is believed that nothing is better than ood sweet grass feed, when it can be had in abun- ance. But in some parts of the season the grass s too much dried up. At these seasons some cul-

tivated roots should be in readiness to supply the deficiency. Various kinds of roots and cultivated vegetables have been used; carrots, ruta baga, mangel wurtzel, sugar beet, and green corn fodder, planted for the purpose, or top-stalks and pump- kins, are all very good, and we do not think there is much difference. Turnips, though eagerly eaten have not been thought to be quite as good. We say that we believe the farmer will be amply paid for the extra trouble of providing some kind of suc- culent food for his milch cows in dry seasons. We have noticed that when only one cow has been kept, by the individual offering for premium, they have most generally obtained the Society's premi- um, and we attribute this to the more particular attention given to feeding one cow, than is com- monly given to many.

My own experience is not much, but I have no- ticed that when I kept only one cow we made as much butter, twelve pounds a week, as when I have kept two, and one of the cows being the same and running in the same pasture. If we did not misun- derstand the commissioner, Mr Colman, the cow for which \$200 was paid, yielded the year previous to sale, within 25 quarts of 200 dollars' worth of milk, at five cents a quart, sold at the door; and the cost of keeping the cow was eightyseven dollars for one year. Now if such an extraordinary produce may be obtained from one cow only, may not cows in general be made to yield much more than they now do, and would it not be economy to give to the subject more attention, by feeding as above propos- ed, and sheltering from all cold and severe weather. Such advice we know has been often given by ag- ricultural writers, but it needs to be often repeated.

The Committee have, with no little difficulty, awarded the premiums as follows :

On Milch Cows.

- To Franklin Bartlett, of Newburyport, 1st prem- ium, \$10
- “ Nathan Tapley, Danvers, 2d prem. 7
- “ Geo. Spofford, Georgetown, 3d “ 5

Heifers in Milk.

- To Joseph Danforth, of West Newbury, 1st premium, \$7

Yearlings.

- To Ebenezer Upton, Danvers, 1st premium, \$3
- “ P. M. Dole, Newburyport, 2d “ 2

R. A. MERRIAM,
NATHAN BERRY,
SAMUEL PERLEY, JR.,
MATTHEW HOOPER,
JOSHUA L. NEWHALL,
SAMUEL DODGE,

Committee.

Georgetown, Sept. 26, 1839.

Franklin Bartlett's Statement.

To the Committee on Milch Cows and Heifers :
GENTLEMEN—The cow which I offer for the So- ciety's premium was bought June 8th, 1839, her calf then four days old. The calf was sold when twentyfour days old, for \$6 00
Thirtythree gallons of milk sold while the calf was with the cow, for 5 33
Milk sold from the cow from June 30th, to July 30th, was 112 gallons, amounting to 17 92
From July 30th to August 30th, 109 galls. amounting to 16 44
From August 30th to Sept. 24th, 80 gallons, amounting to 16 00

Milk used during the time, 16 1-4 gallons, 2 60

Estimated value of the milk, \$61 29

The feed of the cow was a common pasture, without any provender or extra keeping, whatever.

FRANKLIN BARTLETT.

Newburyport, Sept. 26, 1839.

Nathan Tapley's Statement.

To the Committee of the Essex Agricultural Society :
GENTLEMEN—The milch cow which I have offer- ed for exhibition this day, is seven years old. I have owned her three years. I purchased her in the spring, with her second calf. I believe she came into Danvers, in a drove from the country. She calved the last of March. We think her more remarkable for quality, than the quantity of her milk, and having always considered her an extra cow, we were induced this season to keep an ac- count of the butter her milk would produce. The following is the result during eight weeks :

The week ending May 25th, she gave 228 1-4 lbs. milk, which produced				12 1-2 lbs. butter.
The week ending	June 1st,	12 1-4	“	“
“ “ “	“ 8th,	12 1-2	“	“
“ “ “	“ 15th,	12 3-4	“	“
“ “ “	“ 22d,	12	“	“
“ “ “	“ 29th,	10 3-4	“	“
“ “ “	“ July 6th,	12 1-4	“	“
“ “ “	“ 13th,	13	“	“

98 1-4

18 1-4 lbs. of her milk produced about one lb. of butter.

It was not convenient to reserve all her milk af- ter this time, but we are satisfied from the quantity she gave, that she would have made as much but- ter for several weeks after, and still continues to do well.

She has fed in a common clay-land pasture, through the season. On the 22d of June, I com- menced giving her a quart of meal in the morning, and a quart at night; but did not perceive any ma- terial difference, either in the quantity or quality of her milk. Her butter is of fine color and flavor.

Respectfully, yours,

NATHAN TAPLEY.

Danvers, Sept. 25, 1839.

George Spofford's Statement.

To the Committee on Milch Cows :
GENTLEMEN—My cow calved the 3d day of May last. The calf was kept on the cow six weeks, and at nine weeks of age was sold for twenty dollars.

The greatest quantity of milk given in any day was 19 quarts and 1 1-2 pint; averaging for a month after the calf was taken off 18 quarts per day. She has averaged for the last four weeks, 12 quarts per day. I have sold and used during this time 3 qts. of milk per day, and made 32 lbs. of butter. Her keeping has been common pasture, till the last four weeks, which has been fresh feed, with four quarts of oatmeal per day mixed with a pail of water.

Very respectfully, yours,

GEORGE SPOFFORD.

Georgetown, Sept. 26, 1839.

Joseph Danforth's Statement.

To the Committee on Milch Cows :
GENTLEMEN—This heifer was raised by Joseph Danforth, in West Newbury. She was two years

old the 17th day of April last. She has given milk from the 8th of May; she has not had any provender since she was turned out to pasture the first season. The average of her milk has been from the 8th of May to this time, 2 gallons per day. She has had no fall feed this season. She has made from 3 to 5 lbs. butter per week, besides what milk there has been used in the family of 4 and sometimes 5 persons.

N. B. This heifer was taken from the cow when three days old, at which time the cow died, and brought up by hand.

JOSEPH DANFORTH.

Sept. 24, 1830.

Eben Upton's Statement.

To the Committee on Milch Cows and Heifers:

GENTLEMEN—I exhibit for premium my red cow, nine years old. She came into milk on the 16th of last April: the calf was allowed all the milk she would suck for four weeks, (then taken off to raise,) during which time and up to the 20th of May she sold 18 gallons of milk, and churned 19 lbs. of butter.— From the 20th of May to the 1st of July, inclusive, (42 days,) she gave 1838 pounds of milk, an average of 43 3/4 pounds per day, from which, after using what was wanted in the family, 66 lbs. of butter were made. From the 1st of July to the 20th of the present month, 90 lbs. of butter were made. Quantity of milk used in the family, one quart daily. Whole quantity of butter made during the season, 175 lbs.; 40 lbs. of which, made in the month of June, are in the hall of the society. The committee will notice that milk is obtained from three teats only, the other she cut with one of her hoofs in 1837, on the day she brought a calf. Unfortunately the gash could not be healed, and the milk runs to waste. Keeping, ordinary grass feed.

I also exhibit for premium and for the notice of your committee, a heifer, 16 months old, from the above described cow. She was taken from her mother when two days old, and turned away to pasture with a cow that gave four quarts of milk daily, and weaned when 3 1/2 months old. Her keeping during the winter was English hay, and occasionally a little meal; the present season, common pasture feed.

Respectfully, yours,

EBEN UPTON.

Danvers, Sept. 26, 1830.

[From the same.]

ON RECLAIMED MEADOWS.

The committee on reclaimed meadow and swamp land, respectfully report:

That applications for premiums have been made by Daniel Putnam, of Danvers, and William Osborn, of Lynn. The committee have viewed the premises of the claimants and examined the statements which are here annexed, and recommend the Society's first premium of \$20, be awarded to Mr Osborn; and the second premium of \$10, be awarded to Mr Putnam. Mr Osborn has given a detailed account of all his expense and income. This is as it should be; so that our brother farmers may see how profitable it is, and those who have meadows may go and do likewise. The committee have great pleasure in remarking, that they have reason to believe that there is an increasing attention paid to the cultivation of that part of our land which has remained so long uncultivated, and, comparatively, worthless; but which has proved by experience, to

be in point of fertility, surpassed by none, even the fertile prairies of the west. It has been ascertained by experience, that nearly all kinds of grains and vegetables that our climate affords, can be raised on meadow land to good advantage. Four and a half tons of English hay has been cut on an acre in one year. One individual says 100 bushels of potatoes is his usual crop. Rye, oats and corn have also been raised in like proportion. It is an old saying, that it is a good shot to kill two birds with one stone; but in this case more can be done. In removing the stumps and logs with which many meadows are incumbered, the fuel will more than pay the expense; in draining the meadow, the mud will more than pay the expense of ditching, to be carted into the hog-pen, cow-yard or compost heap, then to be applied to upland, as it makes a valuable manure. Two crops will usually more than pay the expense of cultivating them, and then the land instead of being comparatively worthless, in most cases will be worth at least one hundred dollars per acre.

In regard to the best manner of managing meadow land, different persons have different opinions; as it is natural for a person to be partial to his own way if he has tolerable success. Grass or roots may be cultivated profitably on meadows that can be well drained. But there are meadows that cannot be drained so much as would be desirable, or that are occasionally overflowed; such are more suitable for grass. There are meadows within the knowledge of the committee that have produced good crops of English hay without any other dressing than sand; others have used gravel with equal success. Good crops of corn and potatoes have also been raised without manure, sand or gravel being put in the hill. How much better to cultivate land when suitable dressing can be procured from the gravel knoll or sand bank, than to neglect such land and haul manure some miles after paying an extravagant price for it, to be applied to upland, and perhaps not raise an equal crop. Although good crops have been raised without manure as above stated, yet it is thought that a little compost manure may be profitably applied.

Notwithstanding all that has been said, there are those who are so opposed to the new method of farming, as they call it, or so tenacious of the honor of their venerable fathers, that they will not turn to the right hand nor to the left from the path in which they trod. But I would ask whether farmers ought not to keep pace with the improvements of the day, and if they would be as good husbands as those that have passed off the stage before them, whether they ought not to improve just so far as the light of science develops itself?

Again, some say that they cannot afford to make improvements, but it will do for Mr A. or B., who has money. In conversation with an individual who had been improving a part of a small meadow, he said, if I could afford to hire help, I would reclaim the remainder of it. While in conversation, he acknowledged that one crop of hay had actually paid all the expense of cultivation. Now if a man under these circumstances cannot afford to hire help, I know not who can.

It is not the intention to convey the idea that all meadows in all seasons will produce four and a half tons of hay or four hundred bushels of potatoes to the acre, for it cannot be expected. But it is the intention to convey the idea that meadow land will produce more net profit than any other;

as it requires less manure and is less liable to be affected with drought or wet, if it is properly drained.

For the Committee,

JOSEPH HOW, Chairman.

Dec. 31, 1830.

William Osborn's Statement.

To the Committee of the Essex Agricultural Society on Reclaimed Meadows:

GENTLEMEN—Enclosed you will find a copy of my statement of 1838, and I now hand you a statement in addition to that, for 1839, and will only remark in advance, that you may perhaps think the yield of potatoes and the quantity of manure small for the land cultivated; but in addition to the manure, I burnt a considerable quantity of brake and other roots found on the meadow, and used the ashes. The crop of potatoes would have been larger if I had not used lime instead of manure on a large part of the meadow, where in gathering I found a large decrease in the yield. Another cause of decrease was in planting the St. Helena potatoes instead of Chenangoes, which I have reason to think, from a few that were mixed, if I had planted all of that kind, I should have had at least one third more.

Crop for 1838, per account,	\$332 57
<i>Income for 1839.</i>	
30 bu. St. Helena potatoes, at 45c.	135 00
57 " Robans, at \$2,	114 00
2 tons hay, \$12,	24 00
41 bu. of carrots, 25c.	10 25
74 " of sugar beets, 30c.	24 50
Squashes and pumpkins,	2 00
40 bu. mangel wurtzels,	10 00
10 " ruta бага, at 25c.	2 50
Wood for family one year, and for boiler for hogs,	50 00
	\$702, 85

Expenses.

Expenses of 1838, per account, \$246 67	
1839. 74 1-4 days work, farm help,	50 45
Extra labor hired,	26 45
4 cords of manure,	16 00
Seed potatoes,	15 00
1 bushel Rolan potatoes,	8 00
1-2 pound sugar beet seed,	50
" " carrot seed,	37
1-4 " mangel wurtzel seed,	19
4 casks of lime, at 40c.	1 60
35 bushels ashes, at 6 1-2c.	1 50
Hauling " from Lynn,	25
Ruta бага and squash seed,	25
Use of horse and cart,	20 00—387 93

Balance in favor of meadow, \$314 89 with of course an increased value of the land, which is by good judges considered in its present state, worth one hundred dollars per acre, which in addition to the crops taken off, would give a net profit of seven hundred and fourteen dollars eighty-nine cents.

Respectfully, your obt' serv't,

WILLIAM OSBORN.

Lynn, Dec. 11, 1830.

Daniel Putnam's Statement.

To the Committee of the Essex Agricultural Society on Reclaimed Meadow Lands:

GENTLEMEN—The meadow which some of your

number examined last summer, is supposed to measure something more than an acre and a half. In 1835, and in the previous years, it yielded annually about one ton of meadow hay, fit only for litter. In 1835, a small piece was turned over with the hoe and planted with potatoes. Other parts were taken in succeeding years, until the whole has been turned and planted. The potatoes have been matured in the hill, and the yield has been 200 to 250 bushels per acre. Corn, beans, pumpkins, squashes, ruta bagas and carrots, have been tried in small patches, and all have done well.

The past season the crops were as follows:

English hay, (clover and timothy,) on two thirds of an acre, 1 ton,	\$15 00
Winter rye, 1-2 an acre, 14 quarts seed—	
yield 12 1-2 bushels, at \$1 25,	15 62
Black Sea wheat, 1-4 acre, 7 quarts seed—	
yield 4 bushels, at \$1 75,	7 00
Chenango potatoes, 30 poles—yield 46 bu.,	
at 40 cents,	18 40
Sugar beets, 20 poles—yield 106 bu., at	
20 cents,	21 20
Second crop on rye and wheat stubbles, 25	
cwt., at 50 cents,	12 50
	\$89 72

The wheat lodged badly and I was cut while very green; the yield was less than if it had ripened well. Drills were opened with the hoe for the sugar beets, and a gravelly wash from the roadside, mixed with wood ashes, was put into them. The dressing for 18 poles cost two dollars. On the remaining two poles the wash was mixed with bone; cost, nearly two dollars. The beets on the bone appeared to be a little and only a little larger than the others.

The whole meadow has been thoroughly ditched; the muck obtained paid for the labor. Each crop is believed to have paid for its expense as well as similar crops on the upland. It cost eight or nine dollars per acre to turn the meadow at first, and there was an expense of about five dollars in deepening the outlet of the waters.

DANIEL PUTNAM.

Danvers, Dec. 23, 1839.

NOTE.—Sickness and bereavement in the family prevented measurement both of the whole meadow and the several parts.

MASS. HORTICULTURAL SOCIETY.

PREMIUMS FOR FRUITS.

At a meeting of the Committee on Fruits, &c. of the Massachusetts Horticultural Society, held April 18th, 1840, it was voted to offer the following premiums for the year ensuing:

Apples. For the best summer apples, not less than one dozen, a premium of	\$5
For the best autumn apples, not less than one dozen, a premium of	5
For the best winter apples, not less than one dozen, a premium of	5
Pears. For the best summer pears, not less than one dozen, a premium of	5
For the best autumn pears, not less than one dozen, a premium of	5
For the best winter pears, not less than one dozen, a premium of	5
Cherries. For the best cherries, not less than one quart, a premium of	5
For the next best, not less than one quart, a premium of	4

Peaches. For the best peaches, open culture, not less than one dozen, a premium of

For the next best, not less than one dozen, a premium of

For the best peaches, under glass, not less than one dozen, a premium of

Plums. For the best plums, not less than one quart, a premium of

For the next best, not less than one quart, a premium of

Grapes. For the best foreign grapes, under glass, a premium of

For the best foreign grapes, open culture, a premium of

For the best native grapes, a premium of

Apricots. For the best apricots, not less than one dozen, a premium of

Nectarines. For the best nectarines, not less than one dozen, a premium of

Quinces. For the best quinces, not less than one dozen, a premium of

Gooseberries. For the best desert gooseberries, not less than one quart, a premium of

Raspberries. For the best raspberries, not less than one quart, a premium of

Strawberries. For the best strawberries, not less than one quart, a premium of

For the next best, not less than one quart, a premium of

Currants. For the best currants, not less than one quart, a premium of

Melons. For the largest and best water melon, a premium of

For the best musk melon, a premium of

The Committee also offer the Welles' premiums for apples, the produce of seedling trees, which shall have been brought into notice since the year 1829, viz:

For the best summer apples as above, not less than one dozen, a premium of

For the best autumn apples, as above, not less than one dozen, a premium of

For the best winter apples, as above, a premium of

The Committee will determine the days on which the Welles' premiums shall be awarded, of which due notice will be given.

By a vote of the Society, no premiums shall be awarded to any but members of the Society; but gratuities may be given to others, upon the recommendation of the executive committee.

For the Committee,

E. M. RICHARDS, Chairman.

From the Albany Cultivator.

MIXTURE OF FRUITS, &c.

MR. EDITOR—One of your correspondents I perceive puts the following query—"Will the trees from the stone of the peach, plum, cherry, apricot, &c., produce fruit the same quality as did the trees on which they grew?"

From my observation, nature is correct and regular, like producing likeness in the vegetable as in the animal kingdom.

The seeds and stones of the fruit of any tree or plant, standing alone and when the blossoms or the generative organs in them are impregnated from its own genitals, will uniformly produce a progeny of trees and plants, which will produce fruit like the parent tree or plant, *ibus naturæ* excepted.

We set in the same garden, fruit trees of all sorts, and vegetables to produce seeds of all kinds, near to each other. Those which are in blossom, (their

bridal habiliments,) at the same time and of the same genus, will cast the pollen from their stamens or male organs on the pistils or female organs of their neighbors, and thereby produce hybrids, males, mulattoes.

I once planted pits of fine yellow gage plums, from a tree in my garden. Two of the trees produced common blue plums, nearly alike; one a large blue plum, tinged with red, late to ripen, and excellent for sweetmeats; and one produced a yellow gage, about half the size of the parent tree, and of inferior quality. The parent tree stood near to blue plum trees, and the progeny were all hybrids.

I planted the pit of an egg plum from a garden of plum trees of various sorts. The egg plum is nearly the size of the hen's egg, yellow, acid, and ripens in September, and probably the best for sweetmeats. The seedling tree produced plums of similar color and shape, of less than half the size of the egg plum, and ripened the first week in August. The flavor was sweet, except near the stone it was acid, like the egg plum.

I reared a peach tree in the same garden. The first season of bearing, the peaches were large, yellow, and very fine; the next season it bore peaches of red blush. An early red peach tree stood a short distance east of the tree in question, and I presume the east wind prevailed when they were in blossom; at one time.

Most persons who have planted the sweet boiling corn near to the hard yellow or white corn, and even fifty rods apart, have noticed single kernels of the hard, on the ears of the sweet corn; these kernels appear to be wholly of the hard corn, studded by the side of the shrivelled sweet corn. So all the other trees and vegetables mix in the blossoms and produce new varieties.

Apples are improved in the same way, or are rendered inferior. The flavor of choice apples grafted on the stocks of sweet apple trees, is more mild than the flavor of those grafted on stocks bearing sour apples.

If you plant potatoes of one color and kind which were produced near to those of another color, you often collect both colors and sorts from the hill planted of the one color only. [Doubted by the conductor.]

I have said enough to those who observe the works of nature, to establish the proof of the cause of hybrids and varieties in fruits.

It is often asked, which is the best method to transplant trees? The most successful mode that I have practised, has been, to open a hole sufficiently wide to permit the roots to extend in their natural position, not to be cramped. Fill the hole full around the tree with dry and loose earth, such as of onion beds in the garden, and of good quality; then dash in a pail of water, and shake the tree gently. The water converts the fine earth to liquid mud in the hole around the tree; the mud will cling to all the roots; the water will soon sink below, leaving the mass of mud compact around the roots, and no cavities of air. Then fill up the hole again with dry earth, and press it gently down.

If the tree is set in dry earth, filled in, it leaves vacancies of air under the roots, and they starve and perish. Many fine trees are lost in transplanting, by saving the handsome top. The roots of the newly set tree cannot receive immediate nourishment from the loose ground sufficient to support a large top; and while the roots are connecting with the ground, the top dies from want of nourishment. DAVID TOMLINSON.

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, MAY 13, 1840.

STATE OF THE SEASON.

We have been very desirous of obtaining from some one a statement of the season and the progress of vegetation. For years the public depended on the careful reports of the excellent Mr Lowell. We know that there are several farmers who keep such a record; and they would do us a great favor if they would communicate them to us. We have engaged a Salem friend to give us at least once a month his weekly journal. In this case we subjoin his journal of the last year, that every one may compare for himself the present with the past. Our own condition being necessarily unsettled, leaves us no power to do in this matter as we would. We believe the present season is in advance of the past; certainly until the cold weather of the last week. We have had cold easterly winds, a good deal of rain, and scarcely any sunshine for the last eight days. Asparagus, which in the same situation is a tolerably fair test of the season, was this year on the same bed, cut right days earlier than the last year.

H. C.

PROGRESS OF VEGETATION DURING THE MONTH OF MAY, 1839.

(Communicated for the N. E. Farmer)

MAY 4. It has rained hard nearly every night since Monday, April 29th, completely filling the earth with water, and yesterday and to-day the wind has blown strongly from the north west. Ice made this morning of considerable thickness, and although fruit trees in general are very forward and just ready to blossom, they have not sustained any apparent injury. The Isabellas on the back of the grapey have broken very finely, and several of the shoots are showing minute bunches of fruit. The buds of the Hamburghs and Sweetwaters upon the rafters, are just bursting into leaf formation: Horse chestnuts and mountain ash trees have leaved out most greenly.

MAY 11. The weather has been cold and easterly during the week with ice and frosts. Some few of my pears and all my peach, plum and cherry trees are in blossoms. The mountain ashes, horse chestnuts elms, and abeles, have greened out handsomely, and eltingen is fast assuming a summerish aspect. Strawberry vines have commenced blossoming. The vines in the grapey progress slowly. A writer in the Transcript, C. F., thus notices the cold of Wednesday: "This morning at sunrise my thermometer stood at 25°, which is one degree lower than I have any record of its having been in the month of May for 32 years past. Ice was formed in vessels of nearly 1-4 inch in thickness, and the ground was as white with snow as at midwinter."

MAY 18. The weather has been very fine, with but one rainy day during the week, and our spring work has progressed very satisfactorily. We have been planting peas, beans, potatoes. (Robans, Dillinghams and Rouseys), canteloupes and cucumbers. The grapes have grown finely both in the rafters and back of the house, having generally made shoots 18 and 20 inches in length; all of which are showing two or three bunches of fruit. Horse chestnut trees in blossom and a few apple trees.

MAY 25.—Saturday. Since Saturday last the weather has been dull and cold, with raw, chilling winds from the E. S. E. with rain yesterday and on Wednesday. The onions, pursnips, beets and carrots sowed the 7th inst., are just visible upon the rows. The "Tucker" corn planted the 7th inst., is up about two inches. Pease and

beans planted the 15th, are just breaking ground. The vines in the grapey have made rapid growth, and I have shortened in some of the fruit bearing canes this evening. Apples have been blossoming finely since Monday last which is at least a week in advance of the last season.

JUNE 1.—Saturday. During the week past, the weather has been cold, dull and rainy, with raw easterly winds. The vines in the grapey have made some three and four feet of wood, very strong. Peas are blossoming full; potatoes just showing themselves upon the rows. Trees are looking finely. Peas, cherries and plums have got remarkably full, and the foliage of both fruit and ornamental trees is as thick as it generally is by the 17th of June.

RECORD OF THE WEATHER FOR APRIL, 1840

(Communicated for the N. E. Farmer)

Day of month.	Thermometer.		Face of the sky and course of the wind.
	Sun. rise	2 p. m. - 9 p. m.	
1	26	14	36 Clear: cloudy day: snow storm: S. S. E. E.
2	32	40	33 Fair and extremely windy: N. N. W.: 2 inches of snow on the ground.
3	27	56	47 Fair mostly: strong wind S. W.
4	50	61	14 Fair: cloudy, mostly and very windy: S. S. W. W. N. W.
5	36	50	40 Clear: clouds, and extremely windy: W. N. W.
6	24	48	38 Clear: many clouds and windy. W. N. W.
7	27	41	32 Clear and very windy: N. W. N. N. W.
8	24	44	32 Fair: N. N. W.
9	19	50	37 Perfectly clear all day: N. W. W. S. S. W.
10	37	66	54 Fair: uncommonly windy and dusty. S. S. W.
11	46	68	58 Fair: partly cloudy p. m.: S. S. W.
12	56	62	58 Cloudy, with frequent driving winds: S. S. W. W.
13	42	53	40 Clear nearly, and very windy.
14	27	51	44 Fair: N. W., S. W., E. S.
15	12	63	45 Fair: partly cloudy: S. W., N. W., E. S.
16	35	56	47 Fair: N. E., S.
17	41	66	52 Cloudy and fair: strong wind S.
18	51	74	61 Fair mostly and extremely windy: S., S. S. W.
19	50	56	39 Cloudy: fair day: N. N. W., E.
20	29	60	46 Fair: at times cloudy with squalls of rain: S. S. W., N. W.
21	33	50	40 Clear: N., N. E., E.
22	31	60	53 Fair and very windy: S., S. S. W. stormy.
23	55	81	68 Cloudy: the day fair and fine: S. W., W., N. W.
24	57	78	61 Fair and delightful day: N. W., N. N. E.
25	48	74	62 Clear mostly and fine: N. E., E., S.
26	61	82	67 Foggy and cloudy: fair and brilliant day: S. W. thunder shower.
27	57	50	41 Fair and extremely windy: perfectly clear p. m.: N. W.
28	25	60	43 Clear and frosty: great change: S. E., E., S. cloudy, and in the night a storm.
29	45	53	48 Stormy most of the day: E., N. E.
30	46	68	56 Cloudy: fair day and very windy: N. W.

Mean heat of the month, 48.57; do. of the month last year, 46.60. Range of thermometer from 19 to 82—63 degrees.

Average temperature of the month for 24 years, 43° 11. Warmest April in that period, in 1827, 49° 21. Coldest do " " " " in 1818, 23° 10.

With the single exception of 1827, the month past has been the mildest April for more than 30 years; and the season, as indicated by the trees and grass, is one of the most forward that has ever occurred. But few days, however, have been agreeably pleasant, in consequence

of the boisterous winds which have prevailed during the greater part of the month. At present there is a flattering prospect of a fruitful season. Grass and grain look remarkably well, and fruit trees of every kind are exhibiting their buds and blossoms in most exuberant profusion. C. F.

Waltham, May 8, 1840.

MASS. HORTICULTURAL SOCIETY.

PREMIUMS FOR FLOWERS.

A meeting of the Committee on Flowers of the Massachusetts Horticultural Society, was held May 9th, 1840. C. M. Hovey was appointed secretary.

It was voted that the following premiums be awarded for the ensuing year, viz:

Hyacinths: For the best display,	\$5
Tulips: First premium for the best twelve, dissimilar bloom,	10
Second do for the next best twelve do	5
Pansies: First premium for the best twelve different blooms,	5
Second do for the best six blooms,	3
For the best seedling,	2
Paeonies (herbaceous): For the best display,	5
Second do do	3
Best seedling,	2
Geraniums: Best six plants in pots,	3
Second best do	3
Best seedling,	3
Pinks: Best display,	5
Best six flowers,	3
Best seedling,	2
Roses: Best fifty blooms,	8
Second best do	5
Best display of China and other tender kinds,	5
Carnations: Best display,	5
Second do do	3
German Asters: Best display,	5
Second best do	3
Perennial plants: Best display,	3
Second do do	2
Annuals: Best display,	4
Second do do	2

The committee proceeded thus far in making out their list of prizes: the rules and regulations for the government of the exhibition will be passed at an adjourned meeting next week, when all the members are requested to be present.

The first show of the season will take place on Saturday, May 23d, (unless notice be given to the contrary), and for the following articles, viz: Tulips, Pansies, Paeonies and Geraniums.

The flowers and plants must all be in the room by 9 o'clock. A. M. for the inspection of the judges.

Per order, C. M. HOVEY, Secy.

PREMIUMS FOR VEGETABLES.

The Committee on Vegetables of the Massachusetts Horticultural Society, to whom was committed the subject of premiums for 1840, ask leave to report:

For Asparagus, earliest and best four bunches,	\$3
Beans: Large Lima, best two quarts, shelled,	2
Beans: Early Dwarf,	3
Broccoli: Best four heads,	3
Beets: " twelve roots,	2
Cabbages: " six heads,	2
Carrots: " twelve roots,	2
Cauliflowers: " four heads,	3
Celery: " six roots in the season,	2
Corn, for boiling: earliest and best,	2
Cucumbers: best three-pair before 1st Sat'day in June,	4
Lettuce: finest six heads in season,	2
Peas: best specimen of half bushel, before 2d Saturday in July,	4
Potatoes: earliest and best peck,	2
Rhubarb: best dozen spears,	3
Squashes: summer, earliest and best dozen,	3
Squashes: winter, best for season,	3
Pumpkins: best and earliest dozen,	2
Egg plants: best specimen,	2
Brussels sprouts: best specimen,	2
	\$50

The Committee will also award premiums and gratities for specimens of new or valuable varieties, or for any extraordinary specimens of those above named; and they would respectfully but earnestly request all who feel any interest in the Society or in the vegetable kingdom, to

bear in mind and contribute what they can to make this season's exhibitions more interesting and valuable than any that have past.

Respectfully submitted for the Committee,
 J. L. L. F. WARREN, *Chairman.*

Massachusetts Horticultural Society.

Saturday, May 24th, 1840.

We commence our report of the exhibition of flowers for the present season, by a passing notice (which is all we can do at the present moment) of the specimens of *Hyaenulms* presented by Messrs Breck & Co. Many of the clusters were large, well shaped, and the colors various and very brilliant. We saw his bed, in all its glory, at Brighton, and noticed some extra fine sorts, worthy the cultivation of every lover of fine flowers.

For the Committee.

S. WALKER, *Chairman.*

☞ The premium list of the Massachusetts Agricultural Society for 1840, will appear in our next number.

BRIGHTON MARKET.—MONDAY, May 11, 1840.

Reported for the New England Farmer

At Market 160 Beef Cattle, 16 pairs Working Oxen, 60 Cows and Calves, 450 Sheep and 740 Swine.

Prices—Beef Cattle—A short supply at market, consequently quick sales and high prices. First quality, \$7 50. Second quality, \$6 75 a \$7 25. Third quality, \$6 00 a \$6 50.

Working Oxen—A few sales noticed. \$75, \$85, \$90, and \$110.

Cows and Calves—Dull. Sales, \$20, \$22, \$26, \$30, \$32, \$37 and \$45.

Sheep—Sheared. Lots were sold at \$1 84, \$2 00, \$2 50, \$2 75, and \$3 25.

Swine—One entire lot to peddle 4 3-1 for sows, and 5 3-4 for barrows, and two lots at 5 and 6. At retail from 5 1 2 to 7.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northernly exposure, ending May 10.

	May, 1840.	7 A.M.	12 M.	5 P.M.	Wind.

NEW AMERICAN GARDENER.

FOURTEENTH EDITION.

The New American Gardener, containing practical directions on the culture of Fruits and vegetables, including Landscape and Ornamental Gardening, Grape Vines, Silk Strawberries, &c., by Thomas G. Fessenden, late editor of the New England Farmer. For sale by JOSEPH BRECK & CO, 51 and 52 North Market Street.

May 13

MULBERRY TREES, SEEDS AND EGGS.

WILLIAM PRINCE & SON, Flushing, offer for sale very fine large trees of Mulcaulis, Expansa, Elata, Alpine and Broussa Malheries, at low prices and long credits. Also, Alpine, Elata, and Broussa Seeds at \$3 per ounce. Peach and all other valuable varieties of Eggs at \$3 to \$5 per ounce. The seeds and eggs can be sent by mail. 500 pounds Mangel Wurtzel, and 700 pounds Sugar Beet, at reduced prices. 100 bushels genuine Rohan potatoes, 1000 pounds Lucerne Seed. Orders per mail will meet with prompt attention.

May 13.

THE BOYS' COUNTRY BOOK

Of amusements, pleasures, and pursuits, illustrated with 22 original designs. By WILLIAM HOWITT. One of the best books for lads ever published. For sale by April 29. JOSEPH BRECK & CO.

BONE MANURE.

A good supply of ground bones constantly on hand, and for sale at William Chase's mill, one and a half miles north-west of Providence Place.
 A sample may be seen at Remington and Whitman's store, No. 32 Market St. Providence, R. I.
 Also, Bone Mills on a new and improved construction, for sale at the above place.
 April 8. st

FARMING AND GARDE T OOLS.

For sale at the New England Agricultural Ware-house and Seed Store, No. 51 & 52 North Market Street.
 500 dozen Cast Steel and other S. styles.
 500 " Patent Seythe the Snaithes.
 200 " Common do. do.
 100 " Cast Steel Hoes.
 100 " Cracked Neck Hoes.
 200 " Common do.
 100 " Prong do.
 100 " Garden do. superior.
 500 " Hay Rakes.
 1500 " do. Sh. nes.
 100 " Ames' and other Shovels.
 50 " Spades.
 100 " Manure Forks.
 200 " Hay do.
 300 pair Trace Chains.
 100 " Ox do.
 200 " Halter do.
 300 Chains for tying up Cattle
 Together with a most complete assortment of Farming and Garden Tools of every description.
 March 11. JOSEPH BRECK & CO.

FARM FOR SALE.

The highly cultivated Farm of the late Captain A. Delano, situated in North Charlestown, N. H. four miles from the flourishing village of Claremont, containing 160 acres of first rate arable and wood land, with a well finished two story dwelling house with all necessary out buildings, unfailing water at house and barns, two good barns, with shed so by 20 feet, and all necessary buildings for a well stocked farm; together with a good assortment of young fruit trees, nueng which is a fine variety of pear and apple in a flourishing condition, with two good gardens. Terms liberal. Apply to H. F. DELANO, on the premises, or ISAAC HUBBARD, Esq. Claremont. North Charlestown, April 3, 1840. 11*

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

Orders for Bone Manure or Oyster Shell Lime, left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

March 4, 1840 NAHUM WARD.

GARDENERS KNIVES.

JOSEPH BRECK & CO. have this season imported and now offer for sale a few very superior Garden Knives, for pruning, &c. manufactured expressly for Gardeners, and warranted superior to any article of the kind before imported.

Also—a large assortment of Edding Knives, Grape Scissors, &c. &c. April 22.

PURE BLOODED STOCK.

For sale, three young Bulls, 7 to 9 months old, from improved shorn horn Durham, Alderney, and North Devon Stock. Inquire at this office.
 April 29. st

Week's Treatise on Bees

For sale by JOSEPH BRECK & CO.
 April 15.

FIR TREES.

Now is the best time for transplanting Fir Trees. Orders for any variety or size will be promptly attended to.
 May 6. JOSEPH BRECK & CO.

HORTICULTURAL TOOL CHESTS.

Containing a complete set of Garden tools of superior finish and style, recently received from Liverpool and for sale at the New England Agricultural Warehouse and Seed Store.
 May 6. JOSEPH BRECK & CO.

GOLD FISHES AND CANARY BIRDS.

For sale by JOSEPH BRECK & CO. 52 North Market Street.
 April 29.

Northern pulled.

MISCELLANEOUS.

THE FARMER.

A farmer's life is the life for me,
I own I love it dearly;
And every season full of glee,
I take its labors cheerily—
To plough or sow,
To reap or mow,
Or in the barn to thresh, sir,
All's one to me,
I plainly see
'T will bring me health and cash, sir.

The lawyer leads a harass'd life,
Much like the hunted otter;
And 'twixt his own and others' strife,
He's always in hot water—
For foe or friend,
A cause defend,
However wrong it be, sir,
In reason's spite,
Maintain 't is right—
And dearly earn his fee, sir.

The doctor's styled a gentleman,
But this I hold but humming;
For, like a tavern-waiting man,
To every call "he's coming"—
Now here, now there,
Must he repair,
Or starve, sir, by denying—
Like death himself,
Unhappy elf,
He lives by others' dying

A farmer's life, then, let me live,
Obtaining, while I lead it,
Enough for self, and some to give.
To such poor souls as need it,
I'll drain and fence,
Nor grudge expense,
To give my land good dressing—
I'll plough and sow,
Or drill in row,
And hope from heaven a blessing.

ENCOUNTER WITH A BLIND BUFFALO.

A writer of some very interesting papers in the New Orleans Picayune, entitled "Prairie Sketches," gives the following account of killing a blind Buffalo:—

"These animals, although numerous, are seldom seen by the travellers, and their strange peculiarity of running in a circle is but little known. Old hunters, who were with us when we happened to cross one, declared that it was the first they had ever seen, and their fright was as great as the most inexperienced among us, when the huge beast suddenly left its circle and dashed headlong towards us.

It was soon after commencing our afternoon travel, one warm day in August, that we discovered one of these singular creatures, directly in our path. When it first appeared we were much perplexed to determine what it could be, seeming in the distance no larger than a wolf or an antelope, yet being so deeply black we concluded it must be some other animal. As we approached, however, we soon distinguished the enormous hump and peculiar motion of the buffalo. Still we knew not how to account for the creature's running so

continually in a circle, and we supposed it must be battling with wolves that were seeking to slay and devour it. Six of us rode forward, and when about two miles in advance of the caravan we were sufficiently near the buffalo to perceive that there was no other animal, small or large, in sight. We now slackened our pace and advanced slowly, wondering at the extraordinary fancy which seemed to have entered the huge noddle of this wild monarch of the wilderness.

We approached to within three or four hundred yards of the brute, and our surprise still increased at finding that it did not run from us, but all heedless of our presence, kept on coursing and widening its circle. The curious sight caused much merriment among us, and, cracking jokes upon the poor beast, we continued to advance, wondering how near his eminence would suffer us to approach before he would take to his heels.

Our jests continued until within less than a hundred yards of the solitary old bull, and then our merriment was suddenly changed to utter consternation, for the beast made a quick pause in its circular race, gave the peculiar blow with its nostrils, and then, instead of taking to flight as we anticipated, it broke from the circle and came running towards us, with its wild, fiendish looking head bent downwards, ready to gore with its short thick horn, any object in its path. Our little party, riding so compactly together, was instantly scattered far and wide, and the enraged beast, when it could no longer snuff our presence, resumed its circle as before.

The old travellers who were with us, now remembered the stories they had heard of the blind buffalo, and it was very evident that the creature before us was in this condition, by which its singular conduct was accounted for. The animal was old, its meat was not good, we did not want its skin, and were tired of the game of killing the poor beasts for mere sport; yet the wagons were advancing, and should the furious beast rush among the miles, great mischief might ensue, so that it became imperative upon us to kill the old blind bull in self-defence. This, however, we found to be a more difficult task than any we had yet undertaken in the way of hunting, for though we could without danger, get sufficiently near the animal to strike it with our balls, yet its movements were so uncertain that a dozen shots were lodged in other parts of its body before we planted one in its liver, the most vulnerable spot about the buffalo, and that at which the arrow of the Indian and the rifle of the American is always aimed.

The thick blood gushed from the bull's mouth, and we gathered near to see the poor brute die.

Weak and choked with blood, it would pause an instant, start again and run a few steps, stagger, strike at the air with its horns, drop upon its fore knees, and then again rise and dash furiously at the hunter who had ventured nearest. This beast died harder than any that we had killed during the whole journey. It lived full half an hour after the blood spouted from its mouth, and would have lived longer but that we determined to end its sufferings with another shot. A rifle was levelled at the spot directly beneath the shoulder blade, another about four inches from the bone, and almost instantaneously with the report, the poor bull gave a short blow from his nostrils and fell, baring its horns into the ground and tearing up the earth in great fury. We dismounted to examine more nearly the sightless orbs of the beast. The head of no other creature that the writer ever saw, resembled so nearly the

idea that we are apt to conceive of his Satanic majesty. Short, thick, curling horns, almost hidden in masses of black wool, eyes that glare like balls of polished ebony, whose very want of expression excites fearful imaginings; and added to this the desolate region which is its habitation, where it seems neither to herd or have sympathy with any other creature of God's creation. The eyes of this old bull were not black, but white and sightless, and issuing humors which seemed to us like tears as the poor beast lay upon its side, stretching out its limbs in death, and yielding its last sigh to the green prairie that it was leaving forever.

But—Some people always have a *but* which they put in the way of every thing. Inquiring of such a one the character of his neighbor, he replied— "Why, he is a *poofy* fair, clever sort of a man—but *hem!*" But what? "Why—a—hem—why he feeds his darn'd old horse on *punkins!*"

SINA SILK WORMS EGGS.

The Eggs of the celebrated Sina Silk Worm now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The Sina Silk Worm was introduced to France from China by Louis XVI. in 1784, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France.

Each sheet contains an ounce and is signed "Camille Beauvais." Price 8s.

AGRICULTURAL AND HORTICULTURAL TOOLS.

Just received, at the New England Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, per Ship *Giants*, from England, a splendid assortment of Agricultural and Horticultural Implements, viz.

- 100 dozen best Cast Steel Sickles.
- 50 " stout Cast Steel Brar Hooks.
- 25 " Breaking up Hoes.
- 5 " Pruning Chisels with Saws.
- 20 " pair Grass Shears.
- 25 " pair Pruning Shears, with slides.
- 25 " pair Ladies Ivory handle do. do.
- 25 " pair Ladies Cocoa do. do.
- 5 " Large Hedge Shears.
- 25 " Wakefield's Pruning Shears, with slides.
- 10 " Vine Shears.
- 50 " Large Pruning Knives.
- 25 " Budding do. do.
- 15 " Cast Steel Edging do.
- 5 " " Hay do.
- 40 " " Garden Trowels.
- 20 " Bill Hooks.
- 10 " Furze Bills.
- 10 " Gentlemen's Bright Bills.
- 5 " Horticultural Hatchets.
- 40 " Dutch Hoes.

PREMIUM LIST FOR 1840,

Of the Massachusetts Society for Promoting Agriculture.

The Trustees of the Massachusetts Society for the Promotion of Agriculture, announce to the public their intention to offer in premiums not only the sum granted by the government, but the whole amount of the income of their own funds; and as they again omit for the ensuing year their Cattle Show to encourage any purpose in addition to the usual premiums on agricultural experiments, the following premiums:

FOR STOCK,

From any county of the Commonwealth, to be exhibited at Georgetown, in the county of Essex, on *Wednesday, the 30th day of September next*, at the county fair, the following premiums, to wit:

For the best full blooded bull, of an imported breed, not less than one year old, on satisfactory assurance being given that he shall be kept for use, in some county of the State, at least nine months from the day of exhibition,	\$15 00
For the second best ditto,	6 00
For the best milch cow, full blood, of an imported breed, not less than three, nor more than ten years old, with satisfactory evidence as to the quantity and quality of her milk and the manner in which she has been fed,	15 00
For the second best ditto,	6 00
For the best full blooded heifer of imported breed, that has been milked not less than three months, with satisfactory evidence of the quantity and quality of her milk,	10 00
For the best yearling full blooded heifer, of imported breed,	5 00
For the best pair of working oxen, taking into view their size, power, and training,	12 00
For the second best ditto,	6 00
For the best pair of three year old steers, taking into view their size, power, &c.	10 00
For the best milch cow, of native breed, not less than three nor more than ten years old, with satisfactory evidence of the quantity and quality of her milk, and mode of feeding.	15 00
Similar premiums may be expected to be offered for the same descriptions of stock, at the Essex County exhibition in 1841.	
They also propose the following premiums, to be awarded to competitors from any county in this Commonwealth, on stock exhibited at <i>Concord</i> , in the county of <i>Middlesex</i> , at the Cattle Show of the Middlesex County Agricultural Society, on <i>Wednesday</i> , the seventh day of October next, viz:	
For the best bull,	\$50 00
For the next best do	25 00
For the best milch cow,	30 00

For the next best do	20 00
For the best heifer under 3 years old,	15 00
For the next best do	10 00
For the best boar,	15 00
For the next best do	10 00
For the best breeding sow,	15 00
For the next best do	10 00

The distribution of the amount of the foregoing premiums having been apportioned in conformity with the suggestions of the respective agricultural societies of Essex and Middlesex, competitors will be required to comply with the rules and regulations of said societies respectively, and also to give notice in writing of their intention to offer animals for the foregoing premiums, to *Benjamin Guild, Esq. Boston*, Recording Secretary of the Massachusetts Society for Promoting Agriculture, on or before the Monday preceding the aforesaid days of exhibition respectively.

FOR THE BEST CULTIVATED FARMS,

For the best cultivated farm, on which no premium has before been given, of not less than 70 acres exclusive of wood land, regard being had to the quantity of produce, the manner and expense of cultivation and the general appearance of the farm,	\$200 00
For the next best,	175 00
For the next best,	150 00
For the next best,	75 00

To obviate the objections which some claimants for premiums may have to making a written statement of the condition, products and management of their respective farms, as heretofore required, the Trustees propose to relieve them of this trouble by an inspection, either personally or by an agent, of the farms which may be offered for premium.

The person or persons making the inspection, will require of the respective owners or occupants of farms, answers to the following inquiries:

- Of how much land does your farm consist, exclusive of wood land?
- What is the nature of your soil; does it consist of sand, gravel, clay, loam, or peat?
- If of a part or all of the above kinds, what do you consider the best method of improving them?
- How many acres do you till, and how many cart-loads of manure (meaning by cartloads 30 bushels at least), do you generally put on an acre?
- Is your manure applied in its long, or green state, or in compost?
- Do you spread and plough in your manure, put upon fields to be planted with corn or potatoes, or put it into the hills?
- What is your method of ploughing and cultivating green sward?
- How many acres of upland do you mow, and what is the average quantity of hay upon an acre?
- How many acres of grass land do you irrigate; at what season and how long do you allow the water to flow your land, and what is the effect?
- Do you manure the land irrigated, or any other land you mow—how much to an acre, and what kind of manure do you put on?

How many acres of low land, not suitable for the plough, do you mow, and what is the quality and quantity of the hay cut the present year?

What is your method of reclaiming low, bog or peat lands, and what has been your success?

How many acres of corn have you planted the present season—what was your mode of preparing the ground and the seed—the kind and quantity of manure used to an acre—the manner of applying it, and the quantity of corn raised to an acre?

How many acres did you plant with potatoes the present year; what was your method of planting, the manner of cultivating, and the quantity of quantity raised on an acre, and what kinds did you plant?

What number of acres of other vegetables did you plant, what kinds, and how many bushels of produce had you to the acre, and to what use shall you apply them?

How many acres of grain did you sow the present year; what kind of grain and at what times; how was the ground prepared; what quantity of seed did you sow on an acre? If you have raised wheat, of what kind; the nature of the soil, and was it sown with or without using lime?

How many acres have you laid down to grass the present season; at what time in the year did you sow it; how much seed to the acre; and was it sowed alone or with a grain crop?

What are your meads and what your manner of collecting and making manure?

How many oxen, cows, young cattle, horses and sheep do you keep through the year? What is the size of your barn or barns, and have you a cellar under them; is your manure covered?

Are your cows of native, foreign or mixed breed? What is your management of calves intended to be raised?

How much butter did you make this year, and how many cheese, and what proportion of it new milk?

How many sheep do you keep, and of what breed? How many pounds of wool do you get from your sheep? What is your manner of housing, penning, rearing and feeding them, especially in winter, and at the time of lambing? At what time do you shear lamb; and what proportion of their young die, and from what causes?

How many swine do you keep, what quantity of pork did you make, and of what breed were your swine?

What do you feed them upon through the summer months, and on what do you fatten them?

How many cartloads of manure do you take from your hog-styes in a year, and of what materials is it made?

What number of lands is employed on your farm, and what do you pay for labor?

What is the number of your apple trees? Are they of natural or grafted fruits? What use do you make of the fruit?

What number of fruit trees have you, exclusive of apple trees?

Have your trees been attacked by canker worms

or borers, and what is your method of destroying them?

In the cultivation of your farm, do you allow the use of ardent spirits?

The Trustees are desirous that these questions should be answered with as much particularity as possible. The applicant will not, however, be required to answer them under oath, but according to the best of his knowledge and belief.

The Trustees hope and believe that by the method proposed, many important facts may be elicited, and the farming community enabled to derive much useful information from the skill and experience of practical farmers.

N. B. Claims to be addressed to Benjamin Guild, Esq., in Boston, before the first day of October next.

(Form of the Application.)

To BENJAMIN GUILD, Esq., Boston:

Sir,—The subscriber, living in the town of hereby makes known his intention of applying for a premium for the best farm, and offers the same for inspection.

ROTATION OF CROPS.

For the best rotation of crops on the same land, not less than two acres, for three or four years in succession, commencing when it is in grass, \$75 Premium to be claimed in December, 1840 or 1841.

It is expected the applicant will state the quality and condition of the land, when he first ploughs or breaks it up; the manner of preparing it each year specifying the times of ploughing, the quantity and kind of manure used, the seed, whether potatoes, Indian corn, or other grain, planted or sown, and the kind and quantity of grass seed, the time when sown, and whether with grain or alone, and the quantity of produce each year, including the last. The applicant's own statement, signed, but not sworn to, is all that will be required.

VEGETABLE AND GRAIN CROPS.

- For the greatest quantity on an acre,
 - Of potatoes, not less than 500 bushels, \$30
 - " Carrots, 30
 - " ditto on half an acre, 35
 - " Mangel wurtzel, 30
 - " ditto on half an acre, 15
 - " Sugar beet, 30
 - " ditto on half an acre, 15
 - " Ruta baga, 30
 - " ditto on half an acre, 15
 - " English turnips, 20
 - " ditto on half an acre, 10
 - " Onions, 20
 - " ditto on half an acre, 20
 - " Cabbages, free from earth when weighed, 20
 - " ditto on half an acre, 10

For the greatest quantity of vegetables (grain, peas, beans excepted) for home consumption and not for sale, raised for the keeping of stock, regard being had to the size of the farm in proportion to the crop, and to the number of the stock kept, and also to the respective value of the vegetables as food, and the expense of raising the same, 30

- For the greatest quantity on an acre,
 - Of Indian corn, (not less than 80 bushels, 75 lbs. in the ear to be considered a bushel,) 30
 - " Wheat, not less than 25 bushels, 20
 - " Barley, not less than 45 bushels, 20

- " Rye, not less than 30 bushels, 20
- " Dry peas, either broadcast or in drills, 25
- " Dry beans, not less than 10 bushels, 25
- " Mustard seed, 20

It is to be understood that the quantity of land specified above, is in each case to be in one piece. And the claimant of any of the above premiums shall, with one other person, make a statement according to the best of their knowledge and belief, to the following particulars, and shall obtain certificate of the measurement of the land by some sworn surveyor.

The particulars are—

1. The condition of the land in the spring of 1840.
2. The product, and general state of cultivation and quality of manure used upon it the preceding year.
3. The quantity of manure the present season.
4. The quantity of seed used.
5. The time and manner of sowing, weeding, and harvesting the crop, and the amount of the product ascertained by actual measurement, after the whole produce for which a premium is claimed, is harvested, and the entire expense of cultivation.
7. At least forty bushels of the vegetables for which a premium is claimed, (except onions and common turnips,) are to be weighed, and 50 pounds free from dirt, will be considered as a bushel.

EXPERIMENTS, DISCOVERIES AND INVENTIONS.

- For an effectual and satisfactory mode of exterminating the worm, which eats the bark of the tree, \$100
- For a new, effectual, and satisfactory mode of extirpating the borer which attacks the apple tree, 50
- For the experiment of turning in green crops as a manure, on a tract not less than one acre, and proving its utility, giving an account in writing, of the process and the result; and particularly, describing the condition of the ground before turning in the crop, the kind of crop, when sowed, and when ploughed in, 50
- For any newly invented agricultural implement or machine, superior to any designed for the same use, a reward not exceeding fifty nor less than ten dollars, according to the importance of the invention, 50
- To the person who shall prove, to the satisfaction of the Trustees, that his mode of rearing, feeding, and fattening neat cattle is best, 20
- For the greatest quantity of raw unmanufactured silk, not less than ten pounds, raised by the claimant, and presented before the first of December, 1840, 20

PLOUGHS.

The Trustees, considering the plough the most important implement in husbandry, and believing that further improvement may be made in the structure of it, offer the following premiums to encourage ingenious mechanics in any of the United States to undertake it.

1. For the best plough that will turn the sod over and lay it flat; regard to be had to the strength of the plough, easiness of draft, excellence of the work it performs, and its cheapness, \$100
- It is expected that two ploughs, of different sizes of the same model, will be produced.

2. For the best plough that shall lay the sod on edge or obliquely, and not flat; regard to be had to the qualities above mentioned, 75
- It is expected that two ploughs of different sizes of the same model, will be produced.

The Trustees will appoint a committee of at least five intelligent and respectable farmers, from different parts of the State, to meet at some place in the neighborhood of Boston, on some day in October, of which reasonable notice will be given in the N. E. Farmer, to examine and try the ploughs which may be offered. Competitors for these premiums will be admitted from any of the States, and claims may be sent to Benjamin Guild, Esq., Recording Secretary of the Society in Boston, on or before the ninth day of October next.

TREES AND LIVE HEDGES.

- For the best plantation of white oak trees, not less than one acre, nor fewer than 1000 trees per acre—raised from the acorn—not less than three years old, and which shall be in the most thriving state on the first day of September, 1840, \$50
 - For the best plantation, not before offered for a premium, of white, larch and yellow locust trees, each not less than one acre, nor fewer than 1000 trees per acre, to be raised from the seeds, and which trees, not less than three years old, shall be in the most flourishing condition on the first of September, 1840, 25
 - For the best live hedge, not less than 50 rods and which shall be in the most thriving state in 1840, 30
 - To the person who shall offer the best communication on the mulberry tree in relation to silk culture, showing by experiments or otherwise, how it is to be most advantageously managed, what species is best suited to our climate, the effect of the winter thereon, and if injurious, the best remedy therefor, 50
 - Claims for the best plantation of trees above mentioned, together with the proper evidence, must be delivered to Benjamin Guild, Esq., in Boston, free of expense, on or before the first day of January, 1841.
- Claims for the premiums on vegetable and grain crops, and experiments and inventions, together with the evidences required, are to be in writing, and sent free of expense, to Benjamin Guild, Esq., in Boston, Assistant Recording Secretary, on or before the first day of December next, and they will be examined by the Committee previous to the 5th day of December.
- It is understood, that whenever, merely from want of competition, any of the claimants may be considered entitled to the premium, under a literal construction,—yet, if in the opinion of the judges, the object so offered is not deserving of any reward, the judges shall have a right to reject such claims. Persons to whom premiums shall be awarded may, at their option, have an article of plate with suitable inscriptions, in lieu of the money.
- In cases where pecuniary premiums are offered, the Trustees may, having regard to the circumstances of the competitors, award either the Society's gold or silver medals, in lieu of the pecuniary premium annexed to the several articles.
- If any competitor for any of the Society's premiums shall be discovered to have used any disingenuous means, by which the objects of the So-

city have been defeated, such person shall not only forfeit the premiums which may have been awarded to him, but be rendered incapable of being ever after a competitor for any of the Society's premiums.

The Treasurer will pay all premiums awarded on demand.

All premiums not demanded within six months after they shall have been awarded, shall be deemed to have been generously given to aid the funds of the Society.

By order of the Trustees,
JOHN WELLES,
PETER C. BROOKS,
WILLIAM PRESCOTT,
ELIAS PHINNEY, } Committee.

April, 1840.

PLYMOUTH AGRICULTURAL SOCIETY.

REPORT ON COCOONS AND SILK.

There were presented three quantities of cocoons, all of which appeared to be of a good quality.

The greatest quantity was presented by Mary Eliza G. Niles, for which your committee award a premium of four dollars, \$4 00
The next greatest quantity was presented by Thos. Cushman, of Bridgewater, for which a premium of three dollars is awarded, 3 00
The next greatest quantity was presented by Hannah Sparrow, of Middleboro', for which we award a premium of two dollars, 2 00
Hannah Sparrow also presented two ounces of wrought silk, for which a premium of twenty cents is awarded, 20
Sally Pratt, of Middleboro', also presented a specimen of at least five ounces of wrought silk, for which we award the sum of fifty cents, 50

Mrs Franklin Ames, of West Bridgewater, also presented a small specimen of wrought silk—for which we awarded twenty cents, 20
All of which is respectfully submitted.

JARED WHITMAN, Chairman.

Bridgewater, Oct. 16, 1839.

REPORT ON WORKING OXEN, &c.

There were 17 yoke of oxen and steers entered for premium. The first premium of \$8 is awarded to Col. Abram Washburn, of Bridgewater, for the best yoke of oxen raised and trained in the county.
The second premium of \$7 dollars is awarded to Newton S. Mitchell, of Bridgewater, for the best yoke of working oxen.

The third premium of \$5 is awarded to Philander Wood, of Bridgewater, for the second best yoke of working oxen.

For Steers.

The first premium of \$5 is awarded to Ebenezer Pratt, of Bridgewater, for the best yoke of steers.
The second premium of \$3 is awarded to Elias J. Mungo, of Scituate, for the second best yoke of steers.

Your committee likewise recommend awarding one volume of the New England or Yankee Farmer to each of the following persons.

Thomas Ames, of West Bridgewater, one volume New England Farmer.

Silas Robbins, of Bridgewater, one volume New England Farmer.

Salmon Keith, of Bridgewater, one volume Yankee Farmer.
Pevez Crocker, of N. Bridgewater, one volume Yankee Farmer.

Very respectfully submitted,
WILLIAM DUNBAR, Chairman.
Bridgewater, Oct. 16th, 1839.

REPORT ON THE DAIRY.

The number of competitors on butter and cheese were about the same as on former occasions, and the quality would not suffer in comparison with any heretofore offered. In fact, they have seldom met with so many excellent samples of the kind. It was with some difficulty, that they could come to the nice distinction, in some instances, between the first or second premiums,—and in this they may have erred. But the excellent quality of the articles exhibited, serves to show, that with skill and perseverance, as good butter and cheese can be made in the Old Colony, as in any other section of our country. It gives the committee pleasure to commend the handy work of our fair dairy women to the lovers of good living, and to the community generally.

They have awarded the first premium on butter to Mrs George W. Bates, of Bridgewater, \$4 00
2d, Mrs Rosanna P. Fobes, of Bridgewater, 2 00
3d, Dyer Robinson, jr. of Bridgewater, 1 00
Mrs Hannah Crocker, of Bridgewater, one volume New England Farmer.
Mrs Lydia Dean, of Middleboro', one volume Yankee Farmer.

On Cheese.

First premium, George Thompson, of Middleboro', \$5 00
Second premium, Mrs Bethia Bates, of Bridgewater, 3 00
Third premium, Ezra Phillips, of Hanson, 2 00
Mrs Lydia Thompson, of Middleboro', one volume New England Farmer.
Dexter Pratt, of E. Bridgewater, one volume Yankee Farmer.

Although the majority of your committee have passed the meridian, and are in the downhill of life, and have no occasion themselves to speculate in fancy stocks,—yet they would recommend to the young men, just coming upon the stage of action, who are employed in the useful and honorable occupation of tilling the earth, to keep a good look out for the best dairies, and endeavor to secure, for their companions,—graduates from the most useful seminaries.

For the committee,

HOLMES SPRAGUE.

For the New England Farmer.

Out of the abundance of the heart the mouth speaketh.—BIBLE.

I once heard a respectable clergyman observe that in passing a certain dwelling, it so happened that the good woman of the house was on her way to the wood-pile, who certainly not knowing that any one was near, was heard to say, in a tone of voice which indicated not so much anger as discouragement, that she wished she could ever have oven-wood provided in a dry and suitable condition. This single observation was like a short index to a large volume. It told a great deal, and suggested more. The simple fact in the case is, Mr R. her husband, was not a poor man, nor an idle man;

his barn, granary: and cellar, were well filled from year to year: nor was his family purposely stinted in any of the substantial of life, but he thought too little of the importance of what may be called *first* in the every day details of life, nor of the labors, perplexities and disappointment which a want of attention to these things occasion. The passage way to his field, through which he must, of course, frequently go with his team, often several times a day was stopped by a large heavy set of oak rails, which he himself found hard to handle, and in the management of which his younger sons were called to exertions beyond their strength; and for many years the materials which should have been worked into the great barn doors, were so many loose boards which had to be taken away and put up singly every time there was occasion to have the way opened and closed.

Mr. R. had abundance of wood and he was willing that it should be used freely, even liberally. But the difficulty was, it was not cut and prepared beforehand, and never housed. It might burn tolerably well on the lage open fire, but seldom could any be found that was in a suitable condition for the oven. His wife when ever she had occasion for some for this purpose, had to search the whole pile over, and after this labor, would, of course, sometimes fail of finding any in a proper state, and perhaps the very morning referred to, among other little cross incidents, had already made some unsuccessful efforts to get a fire going in the oven, and it was high time, from the state of those materials prepared for baking, that they were in the oven. Is it strange, then, that the expression already quoted, should have escaped from her? she certainly would not have uttered it, had she known that any one was by to have heard. How true it is that our real, every day comfort, or discomfort, is the fruit of what may be called, and by most regarded small things, and as the trifling occurrences of every moment. Good dry oven-wood, cut short and split fine, always in readiness, would make no small addition to the actual comfort of many an excellent wife. So also would a bellows that could draw a long breath—tongs whose feet will not slip by each other, and scatter the coals all around, every time an attempt is made to take up a little fire—a bucket which will not lose half the water during the time it is coming up the well—a door which from some defect in the lock or catch cannot be either opened or shut without a special rick obtained by a long and provoking experience, and even then but half obtained. And so a multitude of other things, little it may be thought individually, but not so in the aggregate, nor in fact individually, when the frequent use converts these little repetitions of inconvenience, like the small items of the merchant's bill, into a most serious and often appalling account. B.

PRUNING PEACH TREES. The trees should be headed down from the top to within say six feet of the ground every third season; it will then throw out more healthy and vigorous shoots, and produce rare fruit. Young wood will be forced out, (if the season is favorable) and the fruit will form upon the laterals, or second years' growth.

If peach trees are trained high, the lower limbs are exceedingly apt to die; the top running up, being exposed to high winds are frequently broken or split down to the very bottom of the tree. I consider the best season for pruning, to be from the last week in May to the first in June.—Salem Observer.

FIRST MANUFACTURE OF BEET SUGAR IN NEW ENGLAND.

The subjoined communication has been some time held in reserve, under the expectation that we should have been sooner prepared to make a full report on the subject of Beet Sugar. As that is now necessarily postponed, we give it as an interesting account and memento of the first attempt made, in New England, to manufacture Beet Sugar to the amount of a pound weight. The sugar produced was much of it of a very good quality. We know the communication will be received with pleasure. We have at this moment no time for farther remark.

H. C.

May 20, 1840.

REV. HENRY COLMAN—Sir—In compliance with your request, I hand you herewith a description of the process pursued by Mr George A. Perkins and myself, in manufacturing the Beet root Sugar, of which I gave you a specimen in the autumn.

The beets raised by me the last season, are the variety known as the White Silesian, yielding a light cream colored pulp, and recommended both by Achard and Dombasle as the best and most productive. The question has been asked, what sized beets are the most profitable, and upon what kind of land should they be grown? The roots upon which we first experimented, were grown upon a dry, sandy field, highly manured in the spring with stable manure and muscle-bed, the latter having been exposed to the action of the frost during the winter; but in consequence of the unusual drought, from which they suffered nearly the entire season of their growth, they averaged scarcely half a pound each in weight, and were harvested early in September; their juice directly from the press marked 11° by the hydrometer. In order to test the experiments, I purchased a quantity of Beets, raised by one of my neighbors, from the same parcel of seed, planted upon what is generally termed rich garden loam, and highly manured. These roots averaged three pounds in weight, were rasped with greater facility, and yielded a much greater quantity of juice; which marked, however, scarcely 6° in the hydrometer. When we take into consideration the amount of fuel and labor, required to evaporate the water from beets of the latter description, is it not evident, that we shall obtain at a less expense, a greater percent. of sugar, from beets grown upon light, sandy lands? Or, in other words, will not 15 tons of beets, grown upon a light soil, yield as much as 30 tons raised upon our best corn land? and, may not the juice of the former, be manufactured at much greater profit than the latter? I have merely mentioned these circumstances, that in case any of my brother farmers should be induced to plant a portion of their fields with beets, with the intention of manufacturing their own sugar, they may not be deterred from it by imagining that they cannot spare an acre of land, sufficiently rich for their cultivation.

The first process to which we subjected our beets was cleaning. This we effected by scraping with knives, which is, however, a long and tedious operation, and we are inclined to give the preference to washing in wooden cylinders, which would be a great saving of labor, where a sufficient supply of water could be obtained.

The machine, used for rasping the beets, was the common grater cider mill, upon which we have made a slight improvement by inserting several

rows of teeth upon the face of the cylinder, by means of which we obtain the pulp in a finer state; and with an iron screw press, which we substituted for the lever we at first used, have extracted 55 per cent. of juice, instead of 35, which was our first maximum. Above the cylinder of the rasp is fixed a deep wooden hopper, of sufficient size to admit the large beet, each one of which is held and pressed on by hand separately. The rasp is turned also by hand, the labor of which is rendered comparatively light, by affixing the handle to the centre of a large wheel, four feet in diameter, over which runs a band drawn tightly into a drum or pulley upon the axis of the rasping cylinder. The pulp falls into a box beneath, whence it is taken by shovels and turned into the bags, which are made of strong Russia duck. Those which we use, are 18 inches long and 12 inches wide, containing about 10 pounds of pulp, and when taken from the press are not more than half an inch in thickness. The manner of folding them, by turning down the two upper corners and lapping over the whole, is similar to that practised in expressing oil. In our experiments we generally press five bags (say 50 lbs. of pulp), at a time, the bags being separated from each other by boards, instead of bundles. From 4 bushels of Beets we obtain about 10 gallons of juice, which has ordinarily yielded us 8 lbs. of sugar.

Having poured the juice into the boiler, a common brass kettle, containing 15 gallons, set in brick work over a furnace, we immediately kindle the fire, and the juice being heated to 180° of Fahrenheit, pour into it a cream of lime, formed by dissolving two ounces of lime in a small portion of warm water, and stir it constantly for the space of fifteen minutes. Then increase the fire until the juice reaches the point of ebullition, when we pour from a pitcher a portion of the juice, reserved for the purpose, upon any bubbles which may show themselves, for the space of thirty minutes. The entire surface of the boiler being now covered with foam, extinguish the fire by throwing into the furnace a pitcher or two of water, permitting the juice to remain undisturbed, until it deposits a sediment and becomes clear, which it will generally do in the space of two or three hours. This process is called defecation of the juice.

The next step is to concentrate it. When the juice has become perfectly clear and limped, but not before, we draw it off by means of a siphon, leaving in the bottom of a boiler a black acrotic matter, which was precipitated with the molate of lime. Should the juice have undergone any alteration by an excess of the use of lime, it will be necessary to neutralize it by pouring in a small quantity of sulphuric acid, diluted with water. We determine the point of saturation by using Tuncnick paper, which, if there is an excess of lime, is colored of a reddish brown. A little practice will soon make one familiar with this part of the process. Having neutralized the excess of the lime, leaving the juice slightly alkaline, and the kettle having been thoroughly cleansed, we return it again to the boiler, and find that it is reduced to about seven gallons, in consequence of concentration and the loss of the black sediment.

Rekindle the fire, and the juice being at 100° of Fahrenheit, commence adding slowly 2 lbs. of animal charcoal, stirring it briskly the while. The syrup having been kept in a state of ebullition some minutes, a thick white scum of a waxy nature appears, which having been skimmed off, we throw

into the kettle a pint of cold water to abate the ebullition, and immediately add the whites of 3 eggs, beaten in water. Increase the fire, stir briskly, and skim for half an hour, or as long as the scum continues to rise; at the expiration of which time, extinguish the fire, and draw off the syrup into the filters, to remain during the night. In the commencement of our experiments, we used conical funnel filters, for which we have now substituted two and even three thicknesses of woollen blankets, secured upon a wooden frame or stand, which we find answer a better purpose.

If the operations of the first day have been successfully performed, the liquor in the morning will be found clear and transparent, marking 20° on the hydrometer, at which point we commence the clarifying process. The syrup is now reduced to 2 1/2 or 3 gallons, and returning it again to the boiler, having first greased the sides thereof with a morsel of butter, to prevent its burning, rekindle the fire, and should there appear any impurities, we add, before heating, the white of an egg, well beaten, removing them carefully with a skimmer. The fire requires to be watched very closely, as there is at this stage, great danger of burning the syrup, which should be kept moderately boiling, until it marks 45° on the hydro meter, when the proof by the thread should be taken, by cooling a portion of the syrup between the thumb and fore finger; separate them suddenly, and if the filament breaks that, curling itself into a horn or spiral, the process is completed. The fire is immediately extinguished, and the syrup conveyed to a tub or cooler, in which crystallization commences, when it must be thoroughly stirred, and thence turned gradually into the moulds, the points or cones of which have been previously stopped with a peg, and the moulds themselves saturated with water, in order that they may not imbibe any portion of the syrup. In the course of an hour or two, a crystallized crust forms itself upon the top of the moulds, which must be carefully stirred and broken, in order to collect the crystals into the centre. At the end of three days, remove the plugs from the points of the cones, set them over the pots to drain, where they are to remain ten days or a fortnight, by which time the sugar will be found to be dry and perfectly crystallized.

I have thus detailed to you, I trust with not too much minuteness, the method pursued by us in several experiments of manufacturing sugar from beets, in which we have been principally guided by the directions of Chaptal and Fontenelle. When one has become acquainted with the process, I am confident there is nothing connected with it, which an intelligent farmer cannot comprehend and practice; and I see no reason why every man who cultivates fifty acres of land, should not have his acre or half an acre of beets, and manufacture not only sugar enough for his family, but a few hundred pounds besides, which he might exchange to advantage with his grocer for many of the comforts, or it may be, luxuries of life.

I remain, respectfully,

Your friend and servant,

PICKERING DODGE.

Salem, Jan. 30, 1838.

See Weed.—This material is considered by many skilful agriculturists as equal to barnyard manure for dressing wheat land. Applied to Indian corn, it is said to be efficacious in preventing injury from worms and drought.

ESSAY ON THE MULBERRY TREE.

The following essay on the mulberry, presented to the Massachusetts Society the last winter, received their premium of fifty dollars. For his indelible exertions, his enlightened zeal, and his generous conduct in relation to the cultivation of the mulberry tree, the distribution of plants and cuttings, the obtaining and circulating authentic information, and for his active and public spirited exertions in promoting agricultural knowledge and improvement in his own county and State, there is no man among us more entitled to respect and honor than its author. He has been many years the Secretary of the Hampshire, Hampden and Franklin Agricultural Society, has been indefatigable in his exertions to promote its objects, has stood by it in its extremity, and we hope may live many years to see it move on with new and powerful success in the improvement of a part of the country, where of all others an enlightened agriculture ought to find its home and its most devoted friends. H. C.

To Peter C. Brooks, Wm. Prescott, E. H. Derby, Josiah Quincy, Jr., and Elias Phinney, Esq's. Committee of the Massachusetts Society for Promoting Agriculture:

GENTLEMEN.—In your list of premiums, under the article "Trees and Live Hedges," is the following: "To the person who shall offer the best communication on the mulberry tree, in relation to silk culture, showing by experiment or otherwise, how to be most advantageously managed, what species is best suited to our climate, the effect of the winter thereon, and if injurious, the best remedy therefor."

Gentlemen, you will please indulge me in the following remarks, and preserve them on your files, to compare with the experience of coming years. Permit me to inform you, that having many years exercised the office of secretary and one of the executive committee of the Hampshire, Franklin and Hampden Agricultural Society, and wishing to introduce to the consideration of the Society the culture of silk, in connection with other agricultural crops, with the full belief that it might be made a profitable business for our farmers, especially if a tree could be introduced and propagated at a moderate expense, which would produce as good foliage and a larger leaf than the Italian white mulberry. Three morus multicaulis trees had been purchased by as many individuals, at one dollar each: these had been engrafted on the white mulberry stock. We then had no conception that the tree could be multiplied any other way. It occurred to me that if the fruit or seed of the genuine mulberry could be obtained, that the trees might be multiplied with more facility and at less expense than by the slow process of engrafting. I wrote to one of the American missionaries, stationed at Canton, China, who was a native of this county, describing to him the leaf of our common mulberry and of the multicaulis, so called, with an urgent request, in behalf of the public at large, and in particular for the benefit of the agricultural society of Old Hampshire, that if practicable, to forward me the seed of the genuine and most approved mulberry for feeding worms and making silk in China. Seed was forwarded me, which the Rev. E. C. Bridgman wrote me was considered the very best, and such as used and most approved by the Chinese for making silk; but that if it did not prove such, he would try again. The seed was received and sown in 1834; and other equally good seed in 1838: both yielding a

splendid thick leaf of 10 by 9 inches, of a beautiful dark green, the buds very close set on the stalks, producing as much, as good, as nutritious foliage, and as easily propagated by layers or cuttings as any known mulberry. Worms have been fed five seasons on the foliage of the large leaf Canton, and for experiment, the present year, worms of the same hatching and same attention have been fed on the foliage of the large leaf Canton separately, on one table or bundle; and others of the same day's hatching and with the same attention, were fed on foliage of the multicaulis and other varieties, (except the Canton) and the worms fed exclusively on the Canton grew much faster than the others: the difference was so great that being seen by gentlemen from different States, while feeding, were judged to be twice as large as the worms fed on the other varieties. But testing them by several weighings with the scales, the difference was found as 5 to 7 in favor of the Canton feed; and when the cocoons were wound, another examination was had in presence of the Rev. Mr Hatch of Alabama, Dr B. Hill of North Carolina, and several distinguished gentlemen of this village, and after various weighings of the cocoons, the result was as 5 to 8 in favor of the Canton feed. A gentleman from Connecticut informs me that he and all of his neighbors have had one and the same result, of feeding on the large leaf Canton and common white mulberry separately, and that the cocoons fed wholly on the Canton, were one third heavier or larger than those fed on the white mulberry. I have myself cocoons fed wholly on the Canton, and others fed wholly on the white, and every one who has seen them, discovers a great difference in the brilliancy and lustre, in favor of the Canton, and when examined under a glass, the difference is nearly as great as between the Saxon and our country wool. The large leaf Canton is more hardy than the multicaulis, yet it is not prudent to expose it to the severity of winter without some slight protection. The roots and stumps left out after taking off the tops to about 2 or 3 inches above the root, may be preserved in a dry place in the cellar or the field, and covering the same with dry earth, and the whole might be preserved in the same way; the slightest covering for the root left out, like the grape, is the best.

There are mulberries in use which are suitable for our climate, some of which, to wit, the Asiatic and Alpine, are estimated to afford as much and as good foliage as the multicaulis; the latter is manifestly too tender to expose to our winter blasts and the large leaf Canton is much too valuable to be unnecessarily exposed; yet the roots may be left out and the tops preserved for cuttings.

It has been found that trees taken up and reset in the spring, have had earlier foliage than the same tree left out all winter. There is great economy in heading down every mulberry, causing a greater number of stalks from the roots and more foliage.

There is no evidence that the multicaulis is used for feed in China. But I have the best of evidence, living and historical evidence, that the tree here called the Canton, is the tree used in China. Gentlemen who are conversant with China, and often visited Canton, have said that silk made in the high latitudes is uniformly 20 per cent higher than silk raised in the low latitudes: such a climate and latitude has New England. It has been demonstrated in this county, that raw silk can be made for two dollars the pound, or even less; and when well reeled is worth six dollars the pound. The gathering of the foliage, feeding the worms

and reeling the silk need not exceed two dollars the pound.

To preserve trees for the winter, they may be deposited in a dry cellar, the roots, and if convenient, the tops covered with dry earth; or may be deposited in a hole in the field, dug before the frost on high and dry ground.

Trees of one season's growth, from seed, layers, or cuttings, should have protection the first year. Freezing of itself does not injure the mulberry, it is the sudden freezing and alternate thawing, particularly in the month of March, which is so destructive to tender mulberries.

I have Cantons, of three and four years of age, standing out winter and summer, and in a vigorous condition, yet they do not produce so much or so large foliage as others which have protection during the winter, or those headed down. I am of the opinion, that America is destined to become a silk growing country; we have abundance of the right kind of dry, warm soil, on which to grow the mulberry, from which might be taken as great a crop in silk as from our best lands devoted to the usual crops.

I am confident in the ultimate success of the silk culture, and could wish that all speculation in the silk tree might cease, and the trees be appropriated to the legitimate object; and that no one could purchase a tree, except for the purpose of growing silk. All of which is submitted, with due respects,
DANIEL STEBBINS.

Northampton, September 2d, 1839.

P. S. October 1839. I am now preparing my mulberries for the winter. Some thousands of Asiatic and Alpine I shall leave standing in the open fields, with tops and branches, which have grown from the root this season, from three to nine feet in height, and had splendid foliage, and shall leave out thousands of the large leaf Canton roots and stumps, the tops preserved for cuttings; a few multicaulis will also be exposed.

Others, of every variety, will be protected in a dry cellar; some set out and some covered root and branch. Others, of every variety, will be deposited in a hole in the open field, dug three feet deep. In the same hole, one parcel will be placed the roots to each bank, and without any earth upon either root or branch. Another parcel will have both roots and branches covered with earth. Another parcel set out and dry earth intermixed. Each of the above methods have been successfully tried, but not every variety in the same place side by side. The trees to be covered with boards and a mound of earth over, that no water should get in. The last winter I left out several hundreds of Canton roots and stumps; some were covered with turf, others with yard manure, others with earth, others with a few weeds or leaves, and others without any covering. The latter were uninjured. Those with the slightest covering the next best; but these covered with earth manure and turf were injured by over heating and some killed both stem and roots; and, on the 31st day of October, found that some sprouts had started from a few of the apparent dead roots, but had not appeared above the surface. Another fact, of some importance, I have found by the two last years experience, that roots which have been taken in and reset in the spring, have earlier foliage than roots or trees which had been left out during the winter.

D. STEBBINS.

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, MAY 20, 1840.

THIRD REPORT OF THE AGRICULTURE OF MASSACHUSETTS.

The Third Report on the Agriculture of Massachusetts, by the Commissioner of Agricultural Survey, is just issued from the press. It constitutes a close printed octavo volume of about 250 pages. It embraces the subject of the wheat culture, containing the results of an examination of nearly four thousand wheat returns; and a general discussion of the culture of wheat, including, its proper soils, cultivation, manuring, diseases, enemies, remedies, preventives, quantity of seed, kind of seed, time of sowing, and the general adaptation of the wheat culture to the climate, soil, habits and condition of the farmers of Massachusetts. The next topic in the Report is the culture of silk, in which every important matter, connected with the subject, is discussed in the fullest manner, according to the best judgment of the Commissioner; and all the valuable information which he could gather from going to the principal localities of the cultivation and travelling more than sixteen hundred miles for these objects, is fully given. The Report embraces a sketch of the history of silk culture in the United States, an account of the principal varieties of trees, the management of the worms by the natural and artificial methods, the subjects of cocooneries and reels, the calculations of products and profits, the manufacture of silk as connected with rural industry; and the circumstances, under which its introduction may be practicable and desirable. The experiments of D. N. McLean, of James Deane, of the Messrs. Cheney, of Joseph Field, and others are given at large; and the great object of the Commissioner has been to present such facts in the case, without exaggeration or coloring, as may be entirely relied upon. He does not design, by this suggestion, to reflect upon the statements which others have given, but only to say, that the sources from which his information has been obtained, are, in his belief, perfectly confidential and responsible; and the inducements to be made from the statements given must be left to the judgment of others.

To the Report he has caused to be subjoined the embellished Synoptical Table of Beauvais, translated from the French, which contains a perfect method of treatment of the silk worm by the improved management through every stage of his progress from the hatching of the eggs to the winding of the cocoon. This is a most valuable paper.

The appendix likewise contains full accounts of the modern Scotch improvements in agriculture, by draining and subsoil ploughing, and various other matters, incidental to the culture of wheat and silk. The appendix likewise contains a highly interesting letter from Dr. Dana, of Lowell, on ploughing in crops for manure. Without reference to any other part of the Report, in respect to which the Commissioner has nothing to say, other than that he has done the best in his power to make it valuable to the farmers, he has no hesitation in saying, that there will be found in the selections and communications in the appendix no small amount of as valuable agricultural information as has ever been laid before the American farming community. It will be seen that this Report is given under a different form from the two preceding. This is owing to an order of the Senate, requiring, as will appear, a particular Report on the subject of Wheat; to which, by their permission, on account of the particular interest felt in the case, he asked leave to

subjoin his Report on Silk. The subjects, however, necessarily embrace a large amount of miscellaneous matter. It is expected that the remaining Reports of the survey will be given as before, with reference to the different counties of the State.

The Report, in this case, being a Senate document, only half the usual number of copies have been printed, the rule of the Senate limiting the editions of their documents to 1500 copies, only a few copies beyond this number have been printed. The Commissioner mentions this as an apology for not making the distribution among his friends and correspondents as liberal as he would otherwise be glad to do.

The Commissioner respectfully renews his claim in this Report upon the candor of his friends and the agricultural community. He finds, as he goes on, the work greatly increases under his hands; and equally increased is his conviction of its importance. It has been the highest gratification to him that its importance is duly appreciated in other parts of the country and in Europe. That he may be enabled to complete it in a manner, which will be just, creditable, and useful to the Commonwealth, he earnestly entreats the aid and communications of the farmers and others interested in the subject in every part of the State and the country; and promises the unremitting devotion of his time and efforts to this great object.

Boston, May 20, 1840.

We had the pleasure, some time since, of receiving from our friend, Capt. Chandler, the following returns of the products of the House of Industry, under his management, the last year. They do great credit to his acknowledged intelligence and skill. It was our intention to have reserved them for the Agricultural Report, but as they have been presented in other forms to the public, we will not longer delay the gratification which our readers will have in examining the document.

REPORT OF THE AGRICULTURE OF THE HOUSE OF INDUSTRY AT S. BOSTON,

UNDER THE CARE OF CAPT. DANIEL CHANDLER.

No. of acres of tillage, 21; of English mowing, 7.	
The work done by the paupers.	
Amount of sales in 1839, (principally vegetables and small fruits.)	\$962 06
Value of produce used or on hand, the principal part of which will be consumed by the paupers,	4146 52
	\$5108 68
English hay—tons, 11 1-2	
Mangel wurtzel—tons, 17	
Barley—bushels, 148 1-2, on less than 3 acres	
Green pease, " 150 Dry do bush.	6
Potatoes, " 1072 Onions, "	516
Carrots, " 233 Blood and sugar beets, "	350
Turnips, " 1125 Ruta baga, "	380
Squashes, lbs. 10,875 Cabbage heads, "	5837
Straw, tons. 3 1-2 Corn fodder, green, tons,	12
Pork, lbs. 7921 Silk, 2 bu. cocoons,	
Honey, lbs. 50 Milk, galls.	3150
Medicinal herbs, \$53 Garden seeds, \$500	
Manure made, cords, 75—Manure bought, 40 cords.	
Pigs sold, 43; average price, \$3 50—\$150 50	
Calves sold, 2, " 6 00 12 00	
Average yield of a cow per annum in milk, 315 galls.	
" weight of a hog fatted at 18 mos. old, 404 lbs.	
Estimated expense of cultivating and securing crops per acre, labor at one dollar per day, including board:	
Indian corn, \$53 00 Wheat, \$22 00	

Oats,	14 75	Barley,	15 50
Rye,	10 00	Potatoes,	42 00
Onions,	76 50	Ruta baga,	52 00
Beets,	58 00	Carrots,	50 00
Garden seeds,	100 00		

The breed of cattle for labor, stall or dairy, of which Capt. Chandler expresses his preference, is "Native."

Extraordinary product. "On one acre of land was obtained, first a crop of pease, 75 bushels gathered green in pods; and two bushels of dried pease; next \$125 lbs. Canada squashes. After which 250 bushels of turnips."

"Mixing bone manure with earth, as follows, one part bone and two parts earth, laid in a heap and moistened with cowyard wash or water, and turned over often, the bone will become completely decomposed in about two months."

"The most profitable articles of cultivation are deemed small fruits and vegetables."

The House of Industry is situated about two miles from the centre of the city of Boston. It has the advantages of a proximity to market, and abundant resources for manure. Its management, however, requires peculiar skill, resolution, and intelligence. As a laboring community, as well as pensioners, it is extremely difficult to regulate it; but the condition of every department, and especially the agricultural, was in the highest measure creditable to its superintendent. We may speak confidently and in terms of equal commendation of the House of Reformation for Juvenile Offenders, and of the House of Correction. We have no room in the present instance, to remark on their moral results and tendencies; but in an economical, penal and humane view, they do much honor to all concerned in their arrangement, management and care.

H. C.

WALKER'S TULIPS AND PANSIES.

We would call the attention of the public to Walker's splendid show of tulips, which are now in all their glory, at the Public Garden, foot of Beacon street, in this city.

This valuable collection has been greatly increased since the last exhibition, and far exceeds any other in America, and embraces all the valuable varieties cultivated in Europe. Amateurs and others who take an interest in the riches of Flora, should not lose the present opportunity to see this magnificent display. The number of blooms does not fall short of 3000. For further particulars see the advertisement.

PANSIES. We have been gratified with a sight of Mr Walker's pansies, which are well worth a ride to his place in Eustis street, Roxbury, to see. He has four or five thousand plants now in all their beauty, and which fill the air with their agreeable odor. Purchasers have the privilege of selecting for themselves such as please their fancy, and we should suppose among the endless varieties in this collection, every taste might be suited.

We have for sale at No. 52 N. Market street, seed of those pansies, saved by Mr. Walker, which we sell at 12 1-2 cents per package. The seed may be sown at all seasons of the year with good success.

J. B.

MASSACHUSETTS AGRICULTURAL SOCIETY.

The proposals of the Massachusetts Agricultural Society for premiums on stock and agricultural experiments and improvements, for 1840, are just issued from the press and will be found in this number of the Farmer. The publication of the premiums has been necessarily delayed, in order to adjust the arrangements with the Middlesex and Essex Agricultural Societies, of the subject of premium for that portion of their funds, which the Massachusetts Society, with great liberality, appropriates to these Societies. We have not time now to go into the particular subjects proposed for premiums. The noble premiums on the best cultivated and managed farms are continued 200, 175, 150, 100, 75 dollars. Two premiums one of 100 and one of 50 dollars, are offered for the best ploughs, of which a public trial is to be had; and the competition is open to every part of the country.

We hope these liberal premiums will excite the atten-

tion which they deserve; and that the disinterested, intelligent and public spirited exertions of the gentlemen who compose the Board of Trustees, will meet a just response on the part of the farmers. We particularly request, likewise, on our own individual responsibility, that the postmasters and others to whom these proposals may be sent, will take all due pains to give them the widest circulation. We shall further remark upon them on another occasion. H. C.

BRIGHTON MARKET.—MONDAY, May 18, 1840.

Reported for the New England Farmer

At Market 160 Beef Cattle, 12 pairs Working Oxen, 30 Cows and Calves, 550 Sheep and 525 Swine

Prices.—Beef Cattle.—We quote to correspond with last week. First quality, \$7 50. Second quality, \$6 75 a \$7 25. Third quality, \$6 00 a \$6 50.

Working Oxen.—A few sales only effected. Prices not public.

Cows and Calves.—Dull. \$23, \$25, \$28, \$30, \$37 and \$40.

Sheep.—A few lots not shewed were sold at \$4 00 and \$4 25.

Swine.—A lot of very small shoats, mostly barrows n 7. Lots to peddle at 6 for sows, and 7 for barrows. At retail from 5 1 2 to 7 1-2, according to quality and size.

HYGROMETERICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded Northerly exposure, week ending May 17.

May, 1840.	7 A.M.	12 M.	5 P.M.	Wind.	
Monday,	11	45	57	50	E.
Tuesday,	12	41	60	46	E.
Wednesday,	13	38	68	58	E.
Thursday,	14	43	72	58	S.
Friday,	15	51	78	60	S.
Saturday,	16	48	68	59	W.
Sunday,	17	38	81	65	W.

WALKER'S SPLENDID TULIPS

Are now open for exhibition, at the Public Garden, foot of Beacon Street, and will continue for several days.

Since the last exhibition, great additions and improvements have been made. The bed, in the present season, will contain upwards of 4000 Bulbs, all of them rare, and the Flowers very beautiful; among them will be found several varieties that obtained the Queen of England's Plate Prize, at Hampton, in May, 1838.

A suitable House, 120 feet long, by 18 feet wide, to comport with the dimensions of the Bed (which is double the usual size) has been erected by the Trustees of the Garden, and all the arrangements have been made with reference to the gratification of the Public.

Admission to the Tulips, Garden, and the Conservatory, 12 cents.

Open every day, (Sundays excepted) from sunrise until sunset. May 16.

SCYTHES, RAKES, &c.

The subscribers offer for sale a very extensive and complete assortment of Scythes, Rakes, &c. consisting in part of 300 dozen of Philips, Messer and Colby's superior Scythes.

- 50 " Metcalf's do. do. do.
- 50 " Taft's cast steel do. do. do.
- 25 " English do. do. Grass do.
- 10 " do. do. do. do. Cradle do.
- 10 " do. do. do. do. Border do.
- 100 " Hall's Rakes, superior.
- 100 " Wilder & Eddy's do. do.
- 200 " Common do. do.
- 100 " Clapp's patent Scythes Smiths.
- 50 " Baker's do. do. do.
- 100 " Common do. do. do.
- 2500 " Austin's superior Rifles.
- 2000 " Cannon do. do.
- 1000 " Scythe Stones.
- 100 " Grain Cradles superior.

They would respectfully call the attention of Dealers and Agriculturists to the above assortment, which consists of many of the best kinds now in use, and which they are prepared to sell at the very lowest prices.

JOSEPH BRECK & CO.

New England Agricultural Warehouse and Seed Store, 51 & 52 North Market Street. May 20.

FOR SALE.

For sale a fine heifer Calf, from one of the best cows in the country, and by the celebrated Ayrshire bull imported by Mr Cushing. Inquire at this office, or at Wmshus's establishment at Brighton. May 20.

FINE DOUBLE DAHLIAS.

For sale by JOSEPH BRECK & CO. No. 52 North Market street, at reduced prices, a splendid collection of Double Dahlias. May 20.

CARNAIION SEED.

The Subscribers have received from Rotterdam, a small quantity of extra fine Carnation Seed, saved from one hundred choice varieties, which they offer at 25 cents per paper. We have tried it, and find that it vegetates freely. It cost us 20 quilters per ounce, and from the representation made, no doubt will give satisfaction to those who may be disposed to try it. We have also very fine carnation seed at 12 1/2 cents per paper. The seed may be sown with good success any time in May or June. JOSEPH BRECK & CO. May 20.

LIME FOR MANURE.

150 Casks Lime, partially damped, will be sold low, by the subscribers, at No. 30 Sea Street, Boston. May 20: 3w SOLOMON PIPER & CO.

FARMING AND GARDEN TOOLS.

For sale at the New England Agricultural Warehouse and Seed Store, No. 51 & 52 North Market Street.

- 100 dozen Cast Steel Hoes.
- 200 " Crooked Neck Hoes.
- 100 " Common do.
- 150 " Long do.
- 100 " Garden do. superior.
- 100 " Ames' and other Shovels.
- 50 " Spades.
- 200 " Manure Forks.
- 200 " Hay do.
- 300 pair Trace Chains.
- 100 " Ox do.
- 200 " Halter do.
- 300 Chains for tying up Cattle.

Also, a complete assortment of Farming and Garden Tools of every description. JOSEPH BRECK & CO. March 11

FARM FOR SALE.

The highly cultivated Farm of the late Captain A. Delano, situated in North Charlestown, N. H. four miles from the flourishing village of Claremont, containing 160 acres of first rate arable and wood land, with a well finished two story dwelling house with all necessary out buildings, unfencing water at house and barns, two good barns, with shed 80 by 20 feet, and all necessary buildings for a well stocked farm, together with a good assortment of young fruit trees, among which is a fine variety of pear and apple in a flourishing condition, with two good gardens. Terms liberal. Apply to H. F. DELANO, on the premises, or ISAAC HUBBARD, Esq. Claremont, North Charlestown, April 8, 1840. 1f*

MULBERRY TREES, SEEDS AND EGGS.

WILLIAM PRINCE & SON, Flushing, offer for sale very fine large trees of Mullein, Expansa, Elata, Alpine and Broussa Mulberries, at low prices and long credits. Also, Alpine, Elata, and Broussa Seeds at \$3 per ounce. Peanut and all other valuable varieties of Eggs at \$3 to \$5 per ounce. The seeds and eggs can be sent by mail. 500 pounds Mangel Wurtzel, and 700 pounds Sugar Beet, at reduced prices. 100 bushels genuine Rohan potatoes, 1000 pounds Lucerne Seed. Orders per mail will meet with prompt attention. May 13.

GARDENERS KNIVES.

JOSEPH BRECK & CO. have this season imported and now offer for sale a few very superior Garden Knives, for pruning, &c. manufactured expressly for Gardeners, and warranted superior to any article of the kind before imported.

Also—a large assortment of Budding Knives, Grape Scissors, &c. &c. April 22.

PURE BLOOD STOCK.

For sale, three young Bulls, 7 to 9 months old, from improved shorn horn Durham, Alderney, and North Devon Stock. Inquire at this office. April 29. 6t

HORTICULTURAL TOOL CHESTS.

Containing a complete set of Garden tools of superior finish and style, recently received from Liverpool and for sale at the New England Agricultural Warehouse and Seed Store. May 6. JOSEPH BRECK & CO.

MISCELLANEOUS.

The following biographical sketch is from the pen of the editor of the Boston Courier. The subject of it filled so large a space of interest and useful action in our community that we cannot doubt it will be highly acceptable to our readers. The justness of the character will be at once acknowledged; and the beautiful and masterly manner in which it is delineated, commend the sketch to the cultivated taste as a high moral and literary gratification. H. C.

From the Boston Courier of April 23.

REV. DR. KIRKLAND.

Died in this city, on Sunday morning last, the Rev. JONAS THORNTON KIRKLAND, formerly pastor of the New South Church, and subsequent President of Harvard University. His funeral took place on Tuesday, at the residence of the President and Faculty, and a large assemblage of the alumni of the University, at the church of which he had been the minister. The services were performed by the Rev. Mr. Young. The remains of the deceased were interred in the Granary burying-place.

The conspicuous position which Dr. Kirkland occupied among us for so many years, his powers of mind, and the graces of his character, deserve, and will doubtless receive, some more extended tribute than the columns of a newspaper permit. He was one of the most remarkable men in our community. His mind was of a high order, distinguished for vigorous sense, sound thought, originality, comprehensiveness and accurate observation. His style was finished and beautiful, terse, graceful and harmonious. His sermons, in spite of an unattractive manner, commanded attention by their wealth of thought and felicity of expression. They abounded in those sharp, pungent, penetrating observations, which could only have proceeded from one who had a keen insight into the human heart, and had unravelled the many-colored web of society; sentences which made one start and blush, as if the preacher knew the very thing we were thinking of. He did a good deal for the literature of our country. Besides his published discourses, sermons, &c., which were all good, he wrote the life of Fisher Ames, which is prefixed to his works, and which is an admirable piece of biography. But his writings, excellent as they are, do but imperfect justice to his powers. He disliked the labors of composition, and wrote no more than his duty required him to. Had his activity of temperament been equal to the powers of his mind, he would have attained a literary distinction inferior to few of his contemporaries, on either side of the water.

He was a man of splendid conversational talents, and those who have not heard him talk, know not the extent of his gifts. He was of a social turn, and delighted to pour out in society the treasures of his wit and wisdom, without measure. He was a spendthrift in his talk, and the very crumbs which fell from his table, would have furnished a tolerable conversational capital. Profound and shrewd observations on men and manners, playful wit, keen-edged but not untempered satire, ripe wisdom, appropriate anecdote, all clothed in language that Addison might have envied—those were the rich tributes which he brought to the social altar, which made every countenance in the

room brighten when he entered it, and young and old hang with equal delight upon his lips. It need hardly be added that he was a great social favorite; generally and warmly beloved; courted and caressed by troops of friends; all which would have turned a weaker head, but had no such effect on him. There was never a healthier mind than his. He saw things just as they were. He valued these attentions, because they gratified his strong social feeling; and the warm atmosphere of love suited his affectionate disposition, but they did not affect his estimate of himself. His self-knowledge was equal to his knowledge of others; and his sound judgment and nice tact taught him, in all situations, to say and do the right thing.

As is well known he was for many years President of Harvard University. He was singularly fitted for the internal administration of a college, and had a good many of the qualifications of a statesman. He had none of those common defects

of the men of the world. He was not a pedant, nor a formal prig, nor an awkward clown. He was a well-mannered gentleman, of graceful bearing and polished address; and would have retained his ease and self-possession in any presence. There was a remarkable mixture of dignity and sweetness in his manners, which inspired respect and won confidence. His reproofs were witty and effective, and his disapprobation was most unwelcome. He had an extraordinary facility in learning the characters of his pupils, and whether he had occasion to censure, to commend, or to encourage, he always did it with singular success, because he always adapted his teachings to the peculiar traits of the individual before him. Many a young man has visibly started and trembled, at hearing some remark made by the President, in his mild, benignant tones, which revealed a knowledge of what was going on within his own breast, such as he supposed none other than himself could possibly have. He carried with him that potent charm—that unthought influence—which spring from genuine sympathy. His warmth of heart drew the young men towards him. The discouraged, the dejected—the sick at heart, found in him support, encouragement, and sympathy. The grace of his manner gave an additional attraction to his genuine expressions of kindness and feeling. He was beloved, respected, and esteemed by all; and his fine, benignant countenance, and winning smile, will ever dwell in the memory of his pupils, who will always reflect with gratitude upon their obligation to him, as a guide, teacher and friend.

CHARACTER. Solomon tells us that "a good name is better than riches," and the experience of every day convinces us of the truth of this observation. Character is of infinitely greater value than either talent or fortune; and therefore, to a young man beginning the world, it ought to be preferred to every other earthly consideration.

Should you be without a capital, a character for honesty, sobriety and industry, will make you master of another man's purse; and money, properly used is a most productive commodity.

Should you have powerful rivals in trade, a character for steadiness and punctuality will procure you numerous customers. In short, with character and good management you may accomplish any thing—without these, nothing.

If you are diligent and attentive to your business, strictly honest in all your dealings, prudent

and economical, and punctual in your engagements, there is no danger of being unsuccessful in the world. You may often hear people talk of luck, and of such a man being fortunate; but do you act as if there was no such thing as luck.—Rely upon it that nine-tenths of the men who are called fortunate may, with far greater propriety, be called prudent.—*Hints to Tradesmen.*

MISSISSIPPIANS GOING TO INDIA TO RAISE COTTON. A late Natchez paper has published facts of some interest to the cotton planters in the United States. It appears that the British Government last year appropriated sixty thousand dollars, for necessary information, machinery, and operatives, for improving the cultivation of cotton in British India. An English agent sent to Mississippi and Louisiana, had succeeded in hiring eight Mississippians and one Louisianian, who are to proceed without delay to India, and on their arrival there, may serve as models for those of the natives.—These Americans are to carry with them cotton gins, as well as plantation tools and handbandy, of the most approved patterns known or used in the Southern States.—*New World.*

The following is related of Roger Minot Sherman, a well known and respected Unitarian prosy clergyman, was engaged by a neighboring congregation to preach for them; but they disliked him so much, that, after the first Sunday, they locked the church doors and had no service at all. The reverend gentleman, however, was not to be "done" in this manner. He remained in the town, and every Sunday, twice a day, presented himself at the church and demanded admission. At the close of the term for which he was engaged, he employed Mr Sherman to bring a suit against the parish for his salary. Thaddeus Betts, the lawyer for the parish, when the case was brought on for trial, turned to Mr Sherman and said—"Brother Sherman, is not this rather a singular principle; a man wishing to be paid for *not* preaching?"—"Brother Betts," was the laconic reply, "if you had ever *heard* my client, you would not think so!"

SILK WORMS EGGS.

Just received, a few ounces of Silk Worms Eggs, from Smyrna, said to be of a superior variety. Price \$3 per ounce, clean seed. JOSEPH BRECK & CO.

April 1.

SINA SILK WORMS EGGS.

The Eggs of the celebrated Sina Silk Worm, now offered for sale, were raised in 1835 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The Sina Silk Worm was introduced to France from China by Louis XVI. in 1754, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France.

Each sheet contains an ounce and is signed "Camille Beauvais." Price 83.

From the Third Report on the Agriculture of Massachusetts.

ON THE CULTIVATION OF WHEAT.

BY ELIAS PHINNEY.

Lexington, Feb. 1, 1840.

DEAR SIR—Your favor of the 25th ult. was duly received. You ask my opinion as to the probable success of the wheat culture in Massachusetts, and request me also to give the results of my own experience in the cultivation of this crop. Allow me, my good sir, the Yankee privilege of answering one question by asking another. Why may not wheat be successfully cultivated in our State? It succeeds east, west, north and south of us, and why not here? Our climate is certainly as favorable as that of any part of the country, and as far as atmospheric causes have a bearing, we have as little to fear from that source as the most favored region on earth. I am aware it may be objected that our lands are not so new as that of many parts of our country where wheat is grown, and that most writers upon the subject consider a granite or light free soil as less favorable to the growth of this crop than a strong, deep aluminous or clayey soil. Supposing these objections to be well founded, they can be at once obviated; the first by deep ploughing and the second by the application of manure and lime. Our old fields which have been subjected to the immemorial usage of shallow ploughing and stunted manuring, will neither produce wheat nor any other crop that will pay the expense of cultivating. The farmer suffers no greater loss from a blighted field of wheat, than from a starved crop of corn. I would recommend then, to farmers who would succeed in the cultivation of wheat or any other crop, to plough deep, turn up and keep at the surface a liberal portion of the subsoil which our fathers have left undisturbed—let them nourish their hungry and exhausted fields with a bountiful supply of manure and lime, and rely upon it, they will no longer complain of blighted crops and unproductive harvests.

The parable of the "sower who went out to sow," contains much agricultural as well as moral and religious instruction. The seed that "fell upon stony ground which had not much earth," like that which is sown upon our shal-ploughed fields, sprung up and grew the better at first, "by reason of its having but little depth of earth," but as soon as the sun was up and the season advanced, "it was scorched, and because it had no root it withered away." Here is an admirable lesson for farmers, and the reasoning of the sacred teacher is as sound and unanswerable in an agricultural, as it is in a moral and religious point of view. Let the farmers then sow their seed upon "good ground," deeply ploughed and liberally and rightly manured, and we shall hear no more of the necessity of legislative bounty as an inducement to the culture of wheat.

My opportunities, however, for noticing the results of the attempts of others in the cultivation of

wheat, and my means of judging of the causes of their failure, where they have been unsuccessful, may perhaps be considered too limited to authorize me to express a decided opinion or enable me to become a safe adviser on this subject. It is, sir, to your experience, to your careful and laborious researches, that the agricultural community must look for much valuable and satisfactory information in a matter in which their interest as farmers is so deeply involved. Allowing me, however, to judge from my own experience, I say without hesitation, I have no doubt as to the successful culture of this valuable crop in all parts of the Commonwealth; I mean with a due application of skill in the management and cultivation of our grounds.

The soil of my farm consists of a thin loam upon a hard, gravelly subsoil, being what geologists call a granite soil, and is similar to that of a great part of the Commonwealth; and I believe by adopting a correct mode of culture, is capable of producing wheat with as much certainty as any other crop.

My first attempt in the culture of wheat was twelve years ago, upon a field of two acres. The soil, a pretty deep loam upon a gravelly subsoil. The field had been planted for two or three years previous with corn and potatoes. I ploughed shal, and not knowing the necessity of lime, I used none. The crop failed, yielding me but little more than twice the quantity of seed sown. The seed was a common kind of wheat procured in the neighborhood. Three years after, I commenced again sowing wheat, but with a different method of culture, and for nine years past have not failed in a single instance of having a good crop. I will give you the result of my practice for the three years past.

In the spring of 1837, I sowed a field of six acres. The field having been then recently set to an orchard, had been under the plough for two or three years and planted with corn and roots. Early in the spring the field was ploughed deep, bringing to the surface a considerable portion of the fresh earth which had never before been disturbed. Two bushels of Black Sea wheat having previously been steeped twenty-four hours in strong brine, and rolled in slacked lime, were sowed to the acre upon the furrow. At the same time I had spread upon the field 150 bushels to the acre of lime and peat ashes, an equal part of each, which had been mixed and lay in a heap for some weeks. The field was then well harrowed and rolled. There was no appearance of blight or rust. At the time of harvesting, I gathered and threshed one acre, probably the best, and it yielded 25 bushels of remarkably handsome grain.

In 1838, I sowed a field of the same number of acres, which was in grass in the spring of 1837. The soil, a thin vegetable mould resting upon a gravelly subsoil, and alternately under the plough and in grass for near a century. In the spring of that year, 1837, the sward was turned over flat, the plough running deep and bringing to the top from one to two inches of subsoil, which had never before been disturbed, and by never cross-ploughing, this fresh earth was kept at the surface. The field

was then rolled and harrowed, and twenty loads of compost manure spread to the acre, harrowed again, and planted with corn. I put in the drills which had been marked out for the corn, twenty bushels of lime and plaster of Paris. I had a pretty good crop of corn, seventy bushels to the acre. In the cultivation of the corn, not a foot of the sward was suffered to be turned back or disturbed. In the spring of 1838, the field was made smooth by the use of the cultivator and harrow, and two bushels of Black Sea wheat, prepared as in the previous year, three pecks of herds grass and one bushel of red top seed sowed to the acre. I then spread on fifty bushels of slacked lime to the acre, and the whole was harrowed and rolled. The straw was large and clean. In consequence of heavy rains, followed by strong winds, about the time of filling, it lodged in some places, and the produce was in some measure thereby lessened. It gave me, however, over twenty bushels to the acre of well filled grain.

In 1839, I sowed a field of eight acres, which until 1838 had been pastured for twentyfive years. The soil, an exceedingly thin and light one, with gravelly bottom, yielding hardly herbage enough to form a sward. Thin as this soil was, in the spring of 1838 I had it ploughed from four to six inches deep, turning it over as flat as the nature of the ground would admit. So much of the gravelly and apparently unproductive material was brought to the surface, that it gave the field a very unpromising aspect. After ploughing, it was rolled and harrowed, about twenty loads of manure from my hog pens put on each acre, and planted with corn, which was cultivated without breaking up the sward. I had forty bushels of corn to the acre. A small crop, but considering the very poor quality of the soil, it was as great as might reasonably have been expected. The method of cultivating this field was more with a view to future operations than for the immediate crop. In the spring of 1839, I broke up the corn-stubble, and loosened the surface with the cultivator and harrow, spread one hundred bushels to the acre of barilla ashes, fifty per cent. of which was lime, sowed two bushels of the same kind of wheat, to the acre, having previously steeped it fourteen hours in a strong pickle, and rolled it in lime. Intending the field for pasture, I sowed a large quantity of all the kinds of grass seed that could be procured, and finished with the harrow and roller. There was no appearance of blight nor rust upon the wheat. Though the heads were short, owing to the thinness of the soil, the kernel was plump and well filled, and makes as white and fine flour as the best Howard street. I cannot state the quantity produced on this field, as it is not all threshed. I judge there will be at least from fifteen to twenty bushels to the acre.

I have now given you, my dear sir, all the practical information which I possess on the subject of the wheat culture, and leave it for you to judge whether my opinion as to its eventual success is well founded.

With me, the wheat crop has as seldom failed, as

any crop which I am in the habit of growing. Less liable to be injuriously affected by the vicissitudes of the season, or the alternation of dryness and moisture, than a crop of corn or potatoes.

With great respect,

Your obedient servant,

MR HENRY COLMAN.

E. PHINNEY.

We have much pleasure in presenting to our readers, which we propose to do in several numbers, some "Wanderings in the West" in the summer of 1839. The manuscript has been kindly put into our hands and we shall avail ourselves largely of its contents. They constitute the journal of an intelligent traveller, a Massachusetts farmer, who at one time, in common with many others, felt a strong disposition to emigrate into this land of promise, flowing with milk and honey. His observations are intelligent and sober, and bear every mark of candor and truth. The "western fever," so graphically described in the introduction, is not now so epidemic, nor of so aggravated a type, as it was sometime since. The observations of this calm observer will moderate its violence with some, and operate as a security against infection with others. At the same time they will greatly assist in the decision of a question which is still agitating the minds of many; and will lead to those reasonable expectations and that sober and deliberate judgment, which may save them from bitter disappointments.

We shall, with leave, give the name of the author at the close of the publication. H. C.

WANDERINGS IN THE WEST IN 1839.

No. 1.

THE WESTERN FEVER.

This dreadful disease has prevailed as an epidemic for several years, throughout New England, and to some extent in the Middle States, and has often proved fatal, if not to the lives, at least to the happiness of those who have had the misfortune to be attacked with it.

Having been afflicted with this disease myself, and seen many others suffering from its attacks, I have become familiar with its symptoms in all its stages. When first attacked, the patient becomes excited with wonder and admiration, dreams of unlimited wealth, in the possession of countless acres in the far west, waving with golden wheat, and corn produced almost without labor—of broad fields of luxuriant grass, supporting innumerable cattle, sheep, and the most beautiful horses; all ministering to the wealth and pleasure of the happy owner; and anon, a splendid mansion rises into view, and spacious stables, and barns filled with the rich products of the fields and meadows, while the farm-yard swarms with pigs and poultry, the neighboring commons abound with game; as he walks out into the lawn he is delighted to see the wild deer lightly bounding away before him, and the crystal streams seemingly alive with a great variety of the most delicious fish, and he enjoys all these without toil or trouble. The possessor of this elysium has apparently less care and perplexity than the eastern farmer who tills the ungrateful soil of New England; his brow is unwrinkled, his placid countenance beams with contentment and unmingled happiness.

At length the excitement begins to subside, and he says to himself, "I will not be led away by idle tales; I will obtain correct information and

deliberate calmly upon the subject, and will be governed by the dictates of sober judgment"—and straightway he reads an extravagant account of the happy land, written perhaps by some speculator in western lands, and is persuaded that his dream is in fact the picture of the real situation which awaits him there. He then compares the very great advantages of the west with those of his present situation, too often overlooking altogether his social privileges, and the pleasures which every person derives from the scenes of his early associations; and, throwing into the balance the numerous petty evils to which he is continually exposed, he comes to the conclusion that the west is altogether preferable to the east.

During this stage, the patient may be seen standing in moody silence in his fields, or perhaps leaning upon his tools, or against the fence, unconsciously whittling away the sharp corners of the rails and posts. His fields appear to him to be poor and sterile, the crops scarcely compensating him for his labor; the grass does not grow so tall or look so green as it formerly did; and even the sun, which whilom shone so brightly upon the beautiful scene around him, now seems to his jaundiced eyes to shine with pale and powerless rays.

Every day his conviction of the superiority of the west grows stronger; he becomes gloomy, and sometimes is overwhelmed with a hypochondriacal affection, popularly called the horrors.

When the disease arrives to this stage, there is no remedy but removal. The patient is aroused only by the prospect of selling his property, he heeds not at what sacrifice;—this accomplished, his former excitement returns—his eyes sparkle, his whole countenance beams with delight,—he packs up a few things which he deems necessary for himself and family, and hurries away to that land where his most sanguine wishes are to be realised.

There may be some variation in the outward symptoms of the disease in different individuals, owing to the difference of constitutions, or to the greater or less violence of the attack; but I think that the above description will be found correct in the main, and the least experienced will be able to detect the disease by the presence of some or all of these symptoms.

On the 16th of May, 1839, I commenced my wanderings. I took a seat in the cars for Providence, where I took passage in the steamer Lexington for New York. On board the boat I found a gentleman from Ohio, who had been travelling for his health, and was returning home. I travelled in his company as far as Pittsburg, and found him an intelligent and entertaining man, and I am indebted to him for much information which was of use to me during my tour. Travellers should be cautious of putting confidence in persons professing to be agents for the different lines of boats, stages, &c. While on board the boat I was exceedingly annoyed by a fellow who called himself an agent for the "fast line" to Pittsburg, and who promised to send passengers through in the fastest line with the very best accommodations, for several dollars less than the regular fare. I afterwards learned that several persons were deceived by such persons, and found, that instead of being forwarded by the packet lines, when they came to the canal they were thrust into dirty freight boats. One gentleman came on board the packet at Harrisburg who had been thus deceived by "lying agents." There are only two packet lines running from Philadel-

phia to Pittsburg—the Express and the Pioneer—one carrying for \$15, the other for \$12. These lines are both owned by the same company; the accommodations of both are good, the difference being in the speed. The Express goes through in three and a half days, and the Pioneer in four.

Leaving New York, we passed down the harbor and coasted the Jersey shore to Anby, thence via railroad to Bordentown, passing the magnificent estate of Joseph Bonaparte, thence down the Delaware to Philadelphia. At the latter place we took passage on the railroad to Harrisburg. After crossing the Schuylkill, we ascended an inclined plane of considerable length, upon the summit of which the locomotive was attached to the train and we proceeded onward, though at a slow rate. The country through which the railroad passes is very rich and beautiful, and as an agricultural district is not surpassed perhaps by any district in the United States. At Middletown we came in sight of the Susquehanna river, and passed by the side of the Pennsylvania canal from there to Harrisburg. This place is 107 miles from Philadelphia, and the time occupied in the passage was 13 hours, and it appeared to me to be an unreasonable length of time to be going that distance upon a railroad, but I was told that the speed of the locomotives is limited by law to ten miles an hour, and I can testify that in this trip there was no violation of the law.

I was surprised to find the capitol of Pennsylvania a small and rather an ill-built village. I was told, however, that there is a good deal of business done, and in a few years it will probably become a large and handsome city.

At Harrisburg we went on board the canal packet. The morning was beautiful; the scene and this mode of traveling were new to me, and I was in high spirits; but a very low bridge taught me a lesson of humility at the very commencement of my voyage, which I did not soon forget. The canal for 15 miles is along the valley of the Susquehanna, and separated from the river in many places only by the tow path. The mountains close in quite to the river, are covered with wood and crowned with round sugar-loaf peaks. The rock is sandstone, dipping to the S. E., with a very large angle, the strata considerably contorted. Some of the cliffs are ragged and overhang the road on the margin of the canal in a very threatening manner, adding wildness to a scene at once romantic and beautiful. Between the hills are little valleys or glens, in which are situated snug and well cultivated farms, upon which I noticed large crops of excellent rye, which I am told is used chiefly to feed horses, the farmers preferring it to any other grain for that purpose; and if the condition of their horses is a proper criterion, they have reason, for I never saw animals in finer condition than the Pennsylvania horses are generally. The Susquehanna is not navigable for steamboats, but when the river is high, great numbers of rafts, arks, and flats, are floated down from the upper country; we saw several of these river crafts passing over rapids which to me appeared quite dangerous. To a person unacquainted with canal navigation, it is surprising with what little trouble the canal boats pass each other. The rule is to pass on the right hand, and of course the horses pass each other on the left hand, the outside team slacking a little to let the inside boat pass over the tow line; in this way the boats pass without any loss of speed. The rate of the packets is about 4 miles an hour.

PLYMOUTH AGRICULTURAL SOCIETY.

The following is a list of premiums awarded by the Committee on Manufactures, Oct. 16, 1839:

To Martin Shaw, E. Bridgewater, calf boots,	\$1 50
‘ Nicholas Vella, do do kip do	1 00
‘ Dr Calvin Pratt, S. do do castor oil,	1 00
‘ Darius Wentworth, Bridgewater, white leather,	1 00
‘ Mrs Abigail Alden, do cloth,	3 00
‘ Ichabod Dunbar, Plymouth, do	1 00
‘ Mercy Sturtevant, Halifax, flannel,	2 50
‘ John Wood, do 2d best do	2 00
‘ Betsey Dunham, Plymouth, 3d do do	1 50
‘ Deborah Porter, E. Bridgewater, 4th do do	1 00
‘ John Clapp, 2d yds C. flannel,	1 00
‘ Mrs Hannah Forbes, Bridgewater, C. and M. do	1 00
‘ Alden Thompson, Halifax, flannel,	75
‘ Lenuiah Hayward, Bridgewater, do	50
‘ Lucy Cushing, Hingham, 1 pr. R. blankets,	2 90
‘ Alfred Wood, Middleboro’, 1 pr. R. blankets,	1 00
‘ Elizabeth Clark, do best carpeting,	4 50
‘ Mercy Sturtevant, Halifax, 2d best do	3 50
‘ Maria McLaughlin, do 3d best do	3 00
‘ Sally Sampson, Duxbury, 4th do do	2 50
‘ Lurana Forbes, Bridgewater, 5th do do	2 00
‘ Harriet F. Snell, E do do 6th do do	1 00
‘ Adam Thompson, Halifax, stair carpeting,	2 50
‘ Lydia Dean, Middleboro’, 2d best do	1 50
‘ Hannah McLaughlin, E. Bridgewater, stair carpet,	1 00
‘ Esther B. Pratt, Middleboro’, best hearth rug,	3 50
‘ Miss Betsey Robbins, Plymouth, 2d do do	2 50
‘ Phoebe Thomas, Middleboro’, 3d best hearth rug,	2 00
‘ Mrs D. L. Cushman, Plympton, 4th do do	1 50
‘ Lucy Marcy, Plymouth, 5th do do	1 00
‘ Miss Rocna P. Forbes, Bridgewater, best W. hose,	1 00
‘ Elizabeth S. Adams, Marshfield, 2d do do	50
‘ Elizabeth Bates, Bridgewater, best pr. worsted do	1 00
‘ Elizabeth B. Sylvester, Hanover, 2d do do	50
‘ Wm. Eames, Duxbury, woollen socks,	1 00
‘ Miss Susan Lincoln, Hingham, cotton hose,	1 00
‘ Sophronia Reed, Middleboro’, 2d best do	75
‘ D. S. Cushman, Plympton, 3d do do	50
‘ D. S. Cushman, do best pr linen do	1 00
‘ Mrs Eph. H. Sprague, Bridgewater, 2d do do	50
‘ Miss Amelia Hyde, do 1 pr silk do	1 00
‘ Hannah Hersey, Hingham, coverlet,	1 50
‘ Mrs Eliza Sampson, Middleboro’, 2d best do	1 00
‘ Miss Jonah Bisbee, Rochester, best quilt,	1 00
‘ Mrs Betsey Turner, do 2d do do	50
‘ Fanny Shaw, Middleboro’, counterpane,	1 00
‘ Miss Rebecca Dunham, Plympton, 2d best do	50
‘ Harriet Howard, W. Bridgewater, diaper,	2 00
‘ Mrs Hannah Fuller, Halifax, 2d best do	1 00
‘ Nabby Phillips, Hanson, linen table spread,	75

‘ Miss D. Leonard, Wareham, linen gloves,	25
‘ Mrs Nelson Wood, Middleboro’, pr worsted drawers,	50
‘ Mary Dunham do best worsted yarn,	1 00
‘ Merry Wood, Halifax, 2d do do	75
‘ W. Eames, Duxbury, factory yarn,	1 00
‘ Mrs Deborah Jome, Pembroke, 1st worsted do	50

\$75 75

MORTON EDDY, Chairman.

REPORT ON STOCK.

The Committee take pleasure in saying, that on no former occasion have they witnessed better specimens of stock than have been exhibited this day for premiums. The pens have been well filled with prime fat oxen, excellent milch cows, and beautiful young stock. The committee regret that they have not more premiums to award, finding so many competitors whose merits and claims are so nearly equal; but being under the necessity of cutting our garments according to our cloth, we have cut and distributed as follows:

- 1st premium of \$6 to Hon. Daniel Webster, for the best fat ox.
- 2d do of \$5 to “ “ “ for the next best ox, driven from his farm in Marshfield.
- 3d do of \$4 to Samuel F. Sanger, of Bridgewater, for the next best.
- 4th do of \$3 to Jarvis Burrih, for the best milch cow.
- 5th do of \$5 to Sidney Packard, E. Bridgewater, for the next best.
- 6th do of \$3, to Seth Pratt, of Bridgewater, for the next best.
- 7th do of \$3 to George Bates, Bridgewater, for the best heifer.
- 8th do of \$2 to James Stetson, W. Bridgewater, for the next best.
- 9th do of \$8 to Martin Swift, Bridgewater, for the best bull.
- 10th do of \$6 to Reuben Thompson, Plympton, for the next best.
- 11th do of \$4 to Calvin Williams, for the best bull calf.
- 12th, do of \$3 to Zepheniah Keith, Bridgewater, for the next best do.
- 13th do of \$3 to Col. A. Washburn, for the best heifer calf.
- 14th do of \$2 to Seth Pratt, for the next best do.

The committee recommend the following gratuities to unsuccessful claimants: 1 vol. N. E. Farmer to Capt. Salmon Howard, W. Bridgewater.

- 1 do do to Galen Howard, of do.
- 1 do do to Isaac Wilbur, Bridgewater.
- 1 do do to Ephraim Snell, W. Bridgewater.

Also, 1 vol. Yankee Farmer to Jacob Robinson, Bridgewater. 1 do do to Joseph Carter, of do. 1 do do to William Gardner, of do. 1 do do to Betsey Gilbert, of do.

All which is respectfully submitted. A. W. OLDHAM, SALMON HOWARD, JOHN TILDEN, } Committee on Stock. Bridgecenter, Oct. 16th, 1839.

PLOUGHING MATCH.

The Committee had eight teams entered for

ploughing: seven appeared at the appointed time and performed their work very much to the satisfaction of your committee. After much deliberation, your committee have unanimously agreed on the following awards:

They award the first premium of \$8 to Abram Washburn, 2d—work performed in 22 minutes.

The second of \$6 to the ploughman of the almshouse of the town of Bridgewater—Silas Robbins, superintendent—work performed in 19 1/2 minutes.

The third do of \$4 to Willard Wood—work performed in 22 minutes.

The fourth do of \$2 to Adin Alger—work performed in 18 minutes.

They also award to Cornelius Holmes one volume of the New England Farmer—work performed in 20 minutes.

To Newton Mitchell one volume of the Yankee Farmer—work performed in 21 minutes.

To Philander Wood one volume of the Yankee Farmer—work performed in 24 minutes.

The ploughs used were all of cast iron and of very good quality. The committee were of opinion that the one manufactured by Prouty & Mears, called the Centre Draft plough, was preferable to any other.

All of which is respectfully submitted. ABRAM WASHBURN 2d, Chairman.

REPORT ON PRODUCE.

The Committee on Produce award the following premiums:

To Galen Howard, West Bridgewater, best crop of wheat—1st premium	\$12 00
‘ Abram Washburn, Bridgewater, wheat	8 00
‘ Albert G. Pratt, Middleboro’—wheat	4 00
‘ Daniel Goddard, Plymouth, best crop of Indian corn	12 00
‘ Abram Washburn 2d, Bridgewater, 2d best do	8 00
‘ Joseph Kingman, W. do buckwheat	4 00
‘ Thomas Frazor, Duxbury, gratuity for oats,	4 00
‘ Dion Bryant, Bridgewater, oats, 2d pre.	4 00
‘ Nathan Whitman, E. do sugar beets	4 00
‘ Galen Howard, W. do carrots,	4 00

\$64 00

Gratuities of New England Farmer to Galen Howard, William Bourn, Hanson ———, Daniel Goddard, Paul Revere, Henry Alden.

Of Yankee Farmer—1 vol each—to Aritas Fobes, Paul Hathaway, Thomas Howard, jr., Thomas Frazor, A. J. Pickens.

COARSE BREAD. Our friend Doctor Holmes, of the Maine Farmer, says we in Maine eat too much fine flour bread for the health of the body or of the pocket. People in western New York, where the Genesee flour comes from, do not, on the average, consume so much fine flour as we do in this State. The Dr. is right in this. Graham was not wrong when he advised the eating of coarse bread. We ought to raise more buckwheat for flitters, and partake more generally of good old-fashioned brown or rye and Indian bread. This is necessary for the health both of the body corporate and the body corporal.—Maine Cultivator.

Ashes sprinkled round apple trees is said to keep them in a flourishing condition.

From the Middletown Constitution

REMARKS ON THE CANKER WORM MOTH

Or Geometra Vernata, and other Insects injurious to the Orchard and Forest Trees. By JOSEPH BARRATT, M. D. Read before the Cuvierian Society of the Wesleyan University, Middletown, April 4th, 1840, and published at their request.

During the last season, great damage was done to orchards by the ravages of an insect generally known by the name of the canker worm. In the latter part of May, the orchards looked as if they had been scorched by fire. The extent of injury done to the crops of fruit is too well known to require any notice here. With a view, however, of gaining all the information on the subject, we then watched the progress of the canker worm, through its different stages, and have had our attention drawn to these troublesome and destructive pests of the apple and elm trees: they have since appeared in great numbers. In turning to works on farming, as well as to books on agriculture and orchards, relating to North America, there is such an evident want of exact knowledge in the names of the insects intended, that it necessarily leads to much misapprehension and confusion: it was thought, therefore, that an acceptable service would be rendered to our farmers and others, by giving the scientific names of insects, as found in books and catalogues on entomology, especially the valuable catalogue of the insects of Massachusetts, drawn up by Dr Harris, and published with the report of the geology of that State.

The canker worm is said to have been first observed in New England in 1666, and in different years it has been found very destructive to orchards, and then for a time, from unknown causes, to have disappeared. In 1808, they became troublesome again in Middlesex county.

The apple it will be recollected, is an imported tree, and by some it has been supposed, the canker worm is also of foreign origin. If this should prove to be the case, it must not be forgotten that several insects very destructive to the timber, and formerly confined to the American forest, have in turn found their way to Europe, and become very injurious to the growing timber there. Professor Peck, of Cambridge, wrote an essay that was published in 1797, on the *Geometra vernata*, or canker worm moth. This essay received the prize of the Massachusetts agricultural society, (\$50,) and was published in their papers. We have not been so fortunate as to obtain a copy of this essay.

The moth of the *geometra vernata* is seen in its perfect state in spring, when it rises from the earth. The female of this, as well as of some analogous species, has mere rudiments of wings. The *Phalena brunnalis*, as its name imports, appears only in winter (in Europe.) This peculiarity retards the progress of the *geometra vernata* through a country, and it is owing to the wingless insects being obliged to crawl up the tree, that a belt of tar serves for a time effectually to keep trees so protected clear of them. The male insect, it is true, is provided with well developed wings, but as they generally ascend the tree with the females, they are as readily destroyed as the other kinds.

In consequence of the early breaking up of the winter of 1840, there being but little frost in the ground, the moths showed themselves on tarred trees of elm and apple very early. From the 20th of February to the 3d and 4th of March they were

numerous: the cold weather of the 5th kept them again in check for a short time.

In the ground they occupy an area of the extent of the tree on which they fed the preceding year as larvæ or caterpillars.

The Hon. H. A. S. Dearborn, formerly President of the Massachusetts Agricultural Society, made a series of observations admirably conducted in the year 1830, on the canker worm moth. He commenced his operations by tarring on the 4th of March, in his orchard, the apple, quince, plum, apricot, cherry, and elm trees, with the honey locust, having found all these subject to its attack. As the weather continued cold and the ground frozen for some days, the moths did not show themselves that year till the 13th of March; and on the evening of the 16th, the female moths began to ascend the trees in considerable numbers, as well as on the following nights, (with some exceptions, owing to the state of the weather,) until the 20th and 21st, when innumerable males came forth, previous to these last days, but few had been seen. On the 23d, both male and female moths were so numerous as to bridge over a belt of tar by 8 o'clock, that had been applied the same afternoon, and it became necessary to renew it at night. The moths of both kinds continued to ascend the tree till April 8th, with but few of the females during the last period.

The eggs laid by the moths began to hatch April 30th; they continued to prey on the leaves till June 5th, when the small caterpillars or worms commenced descending by delicate threads and entered the earth: this they do in the night season. It was found by Mr Dearborn that the caterpillars of the *geometra vernata* left the trees on the 5th, 6th, and 7th of June, and it was difficult to find one on the 8th. On examining the earth beneath the trees, he found they had penetrated from 1 to 3 inches below the surface, and they had all changed to the chrysalis state, by the 4th of June.

The *geometra vernata* sometimes makes its appearance in the autumn as well as in spring; they then deposit their eggs, which hatch about the same time with those laid in spring. They were observed in the month of October 1831, in the vicinity of Boston, and the writer had also seen them in autumn. The winters of 1830 '31 being mild, they were observed ascending the trees every month.

Dr Harris, the celebrated entomologist of Boston, supposes the *geometra vernata* may be identified with the *phalena brunata* of Linneus, or winter moth of Europe. It is thus described in Rees's Cyclopaedia: *phalena brunata*—wings yellowish with a black streak, and paler behind: the female is apterus (without wings) and of a brown color.

We do not, however, find in English works on insects, any notice of its ravages in orchards similar to what takes place in this country. The apple tree is invested with the larvæ or caterpillars of several insects; and especially with a caterpillar that is troublesome and voracious, the product of a different moth.

Before closing these remarks on the *geometra vernata*, it may be well to name here (to avoid confusion) some other insects that infest the apple tree.

Every tree or plant is more or less infested with insects, and the forest trees as well as those of the orchard, are at times attacked by numerous caterpillars: a little attention in spring will generally be sufficient to destroy the nest of the tent-making insect, generally known as the *caterpillar*. This is the larvæ of the *Chisocampa castrensis*, an imported species. This is the most troublesome to orchards

in England; but is not to be named with the *geometra vernata* or canker worm, for the desolation it has caused in this vicinity, as well as through different parts of the northern States.

Among the insects that infest the leaves of the apple tree, may be named several kinds of *Aphides*, and also a caterpillar that preys on the bark, and which changes to a moth called the *Tinea corticulis*.

The *Tortix pomonæ* or apple worm, also feeds in the centre of the apple, and beside causing its premature fall, is productive of much injury to the fruit. The last named insect should be well known to orchardists in all the stages of its existence, as well as the means that have been adopted for eradicating it.

It gives us much satisfaction to learn that Massachusetts, in her most valuable and ably conducted State surveys, has, besides furnishing an extensive and valuable catalogue of insects, caused a work to be drawn up expressly on the insects injurious to agriculture, &c. with the details of the most effectual means yet known of destroying them. This work undertaken by Dr T. W. Harris, will soon we learn be printed, and it should be extensively circulated.

The work would be more directly useful to the public, if it contained figures, in the manner of some of the admirable British publications on entomology, or similar to that beautiful work, the Entomologist's Text Book, by J. O. Westwood, F. R. S., 12 mo., London, pp. 429, with colored plates; or the excellent and popular work in 3 vols. on insects, with figures, forming part of the series of the Library of Entertaining Knowledge. These works should have a place in every public library and lyceum, and there ought besides to be preserved, collections of insects, especially those that are destructive to the fruits, &c. If these measures were duly attended to, young persons would soon attain a competent knowledge of these depredators, that are at this time doing extensive mischief to the orchards, fields, gardens and forests of our country.

It has been estimated that in one county in England the injury done to the turnip crop alone by a small fly, the *Haltica nemorum* or turnip fly, in Devonshire in 1786, amounted to £100,000 sterling.

A farmer in the county of Middlesex stated to us a short time since, that his orchard, which used to yield him 500 barrels of cider annually, did not last year yield a single apple! If we may judge from what we have witnessed the last two years, it would seem that the apple trees would be destroyed, at least those in which the insects are suffered to have their course. The locust tree in some of the northern States is now so much infested with a boring insect, the *Clytus pictus*, as to be useless, and to be rendered even a nuisance.

The black walnut tree in some places is so much frequented year after year by numerous caterpillars, that trees have been cut down to avoid these pests.

The elm besides being preyed upon by the canker worm, is attacked by another insect, the spiny caterpillar. This proves to be an introduced species; and as there are some facts in relation to it of interest to the entomologist, we will give it a passing notice. In Europe it is known to feed upon the birch, poplar and willow, but in this country it deserts the poplar and feeds on the willow and elm. About the 15th of June these large and spiny caterpillars are seen in numbers to quit the elm, and by the 30th of the same month, they are abroad

as the beautiful purple butterfly, the *Vanessa antiopea* or the Camberwell Beauty.

On referring to Jardine's Naturalists' Library, vol. 3, p. 168, pl. plate 18, fig. 2, (which see for an excellent figure and description,) we find it there stated that this species of *Vanessa* had not until within four or five years, been seen for nearly forty years, when it was exceedingly abundant. Here is a striking instance of a butterfly of rare occurrence in England, that has become common in the northern States of America, and is seen regularly year after year, and might be highly prejudicial to the elms, but for the numerous enemies that prey upon it in its different stages, and serve to keep the species within due bounds.

If we had not already extended these remarks to a greater length than was intended, we might enumerate some of the ingenious methods that have been tried to destroy the canker worm. Tarring the trunks of the trees in spring while the motus continue to ascend, and the circular lead trough filled with CaO , are perhaps the most efficacious artificial means that have been adopted. The lead trough, we learn, has been thoroughly tried at New Haven with the elm trees; and we have seen one apple tree in this city so protected. These means are rather expensive.

One of our farmers last season saved half his apple trees by the following process: finding his trees full of the canker worms, he took air slacked lime and had this freely dusted from the top of each tree. This was done while the dew was upon the leaves. Our informant states that all the trees so treated, were rescued from the devouring insects, while the rest in the same orchard, in which no lime was used, became a prey to the worms.

It appears to us that more effort should be made to destroy the caterpillars at the time they quit the trees, as this period occupies but about 3 nights; they are then in their most defenceless state. If the ground beneath the trees could be newly turned up and made smooth and strewn with quick lime; or in orchards with grass, perhaps some noxious fluid might be used to destroy them at once.

The great and important service rendered to orchards, gardens and fruit trees by small birds, is not, we apprehend, fully appreciated by the people of Connecticut. Flocks of blackbirds, when unmolested, pass much of their time in the orchards in spring, and are known to devour great quantities of insects.

One of our best informed farmers assures us he has the greatest confidence in the presence of the blackbirds and robins, in securing his farm and fruit trees from the depredations of insects. So far his numerous fruit trees have been exempt from the canker worm. At this time, April, he says there are three large flocks of blackbirds and great numbers of robins, that are constantly on his premises, and enjoying his protection. If this gentleman's example was more generally followed with regard to the protecting of birds, we feel satisfied there would soon be less reason to complain of the destruction caused by insects.

Another species of bird, of extraordinary use in the orchards, is the cedar or cherry bird, *Bambycilla carolinensis*—see a figure in Nuttall's Ornithology, vol. 1, p. 248. Mr N. observes, that "before the ripening of the cherries and mulberries, for hours at a time, they may be seen feeding on the all-devouring canker worms." From the gentle habits of this bird, it is an easy prey to rapacious guncners, for we cannot call such persons sportsmen.

There was a time when the crows in Massachusetts were destroyed. The farmers soon found great increase in insects injurious in their pastures and fields—and the crow bounty was annulled.

We have been informed that in one portion of Massachusetts where the greatest care was taken to prevent the wanton destruction of small birds, there has been a remarkable exemption from all noxious insects, while all round this district was suffering from them. From causes perhaps not fully understood, the proportion of birds varies in different seasons. Last spring, in the county of Middlesex, blackbirds and robins were very scarce, and the small birds generally were seen in much less numbers than is usual.

Since penning the above remarks, we have had the satisfaction of meeting with a most interesting communication, by Mr E. C. Herrick, in the American Journal of Science for April, 1840. Mr H. has paid great attention to the wheat fly, and has, it appears, directed his attention to the geometra venata. He finds that the minute attacks the eggs of the canker moth. The insect belongs to the genus *Platygaster* of Latreille. As yet there has been but one American species of it described, although the foreign species are very numerous. This minute parasite appears to be abundant, and promises to be of especial service in checking the increase of the devouring canker worm. We regard the observations of Mr Herrick as being valuable. The disappearance of the canker worm from time to time, may in part be owing to the rapid increase of the minute insects he has directed our attention to, with perhaps other insects allied to it, increasing in such numbers as to destroy the eggs of the canker worm.

The wheat fly *Cecidomyia tritici*, and destructor, which occasioned so much alarm some years since, was found to be kept in check as well as nearly destroyed by a minute parasitic insect, which deposits its eggs in the bodies of the minute larvæ of the wheat fly, or Hessian fly, as it was improperly called. Mr Say has described this most important insect under the name of *Ceraphron destructor*.

The extraordinary provisions in nature, by which certain insect tribes multiply rapidly to keep others in check, would be a subject of peculiar interest, had we leisure now to follow it into its details. We may perhaps be induced to attempt it at some future time.

ORDER AND REGULARITY.

The patriotism of men may be doubted, (or at least their State pride questioned,) who have no order, taste nor convenience about their homes. Men cannot be happy, (at least married men,) whose families are subject to perpetual change of residence. Females are not likely to form attachments to their home, without something to ornament and adorn it, which may be rendered doubly dear by their assistance in that decoration. Hence, until the people of Mississippi look on their residences with that soul-cheering emotion inspired by the poet, of "home, sweet home,"—in vain may we look forward to permanent improvement, from the efforts now on foot in the State, through the State and county agricultural associations. In travelling through the country, you are forcibly reminded, at almost every plantation by the way, of the commendable enterprise and industry every where to be met with, and yet equally impressed with the reflection, that apart from the wide-spread cotton

fields and gin houses, that the inhabitants are but the tenants of a day. But few farmers present to the eye of the traveller the neat country cottage, partly hid by the ornamental shrubbery surrounding it, with the apple, the peach, and other necessary fruit trees, standing in bold relief;—teasing the eye and the appetite. Though this part of the culture may not be a source of much profit to the owner, yet it may well be questioned whether without it there can be those endearments to our homes that follow with it; will not the family ties be strengthened by that which may be the joint care of all its members?—our daughters pointing to the woodbine, the honeysuckle, the jessamine, and other vines which they have trained; and our sons to the trees they planted. If the education of our sons as farmers be desirable, may it not with propriety be asked, how there can be a plan better calculated to "teach the young idea how to shoot"?—How essential then, that order and good taste should surround the dwelling, either in ornamental or vegetable culture. Whether we intend our sons for farmers or for professional life, is it not more likely that being thus surrounded, their minds will become better systematised, than when confusion or no order at all prevails?

"Train up a child in the way he should go, and when he is old he will not depart from it." Train them up as farmers, and whether we are fond of the ornamental or the more profitable portions of culture, let order and good taste abound, thereby laying the foundation of a proper system of education for the young farmer.—*Mississippi Farmer.*

From the New Genesee Farmer.

TO PREVENT SMUT IN WHEAT.

MESSRS EDITORS—As many farmers are slow to believe in the efficiency of brine and lime in preventing smut in wheat, I am induced to give additional testimony in its confirmation.

As our winter wheat is rarely smutty to any extent, we have never prepared that seed by brining and liming. But our spring wheat having formerly been more or less smutty, we now prepare our seed in the following manner: After putting the seed into water, to separate the light kernels and oats, if there should be any amongst it, we put it into a tub, and pour strong brine, about blood warm, on to it till it is completely covered. After it has steeped three or four hours, we take it out in baskets, in which we let it stand until it is sufficiently drained; then we spread it on a barn floor, and rake in fresh slacked lime until the wheat becomes dry, when it is fit for sowing.

The past two seasons we have prepared our seed wheat in this way, and not a kernel of smut has been found in the crops raised from it; while our neighbors who neglect this preparation, are generally troubled with smut.

CASSANDER.

Important Discovery.—A very important discovery in Paris is spoken of. A gentleman has succeeded in making very excellent bread from beet root, mixed with a small portion of potato flour. It is said that this bread is of very excellent quality, and can be sold to the public at so low a price as two sous per pound.

Every one can accomplish some good in the world, for every one can set a good example.

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, MAY 27, 1840.

SILK CULTURE.

We have recently given our views so much at large on the subject of the silk culture, in our Third Report of the Agriculture of Massachusetts, that it seems almost a work of supererogation to call the attention of our readers again to this topic. Yet that statement may fall into comparatively so few hands, that we shall be pardoned, we trust, for again referring to it. There will be found in that report some few verbal errors, which indeed constitute errors of sense, which were accidental, and which we think the intelligent reader will at once detect and correct; as, for example, where it is said, on the 11th page, in speaking of Sharpe's new variety of mulberry, that the *tree* is of an average size with the multicaulis, it should read the *leaf* is of an average size with the multicaulis. Excepting, however, some typographical errors of this kind, we cannot upon reflection abate or alter the views there expressed on the general subject.

We are often asked in regard to the silk business, will not this *humbug* soon be ended? or, is it not all over? We know very well, like-wise, of the sacrifices at public sales of mulberry trees, that have been made, which considering the estimation in which they were held only a year since, seem almost sacrilegious. We have known trees which a year ago would have been considered an eligible purchase at fifty cents per tree, sold for a cent and for half a cent apiece; and thousands and thousands offered without the owners being able to obtain even so much as two mils apiece for them. We have in fact known six or seven thousand of plants of the best description, used for heating the oven for a single batch of bread; and twenty thousand consumed in a single fire on the field, merely for the purpose of getting rid of them. We can easily suppose that such a spectacle must draw scalding tears from the eyes of some persons; and we honestly confess, so far from any complacency in such results, we are more than half disposed to weep over such lamentable and painful examples of the disappointment of sanguine hopes, and of the issue of an infatuation of the human mind, which if brought on by an unbridled and insatiable avarice, showed equally the weakness of the mind and the power of passion to blind and pervert the judgment and render it callous to all the teachings of experience and the counsels of prudence. But in spite of all this, we have entire confidence in the ultimate success of the silk culture, so as to afford an ample compensation to labor, and to meet all reasonable and just expectations. The silk culture is no *humbug*; we detest the word, but we are compelled in common parlance to adopt it. Whatever may be said or thought of the mulberry tree speculation, it ought not to be lost sight of in this matter, that the speculation in mulberry trees and the production of silk are matters entirely distinct from each other. Nine tenths of the persons who have been engaged in the raising of multicaulis trees, never had a thought of producing silk. Their success or their failure therefore, is no test of the judgment of the sober and intelligent, who have looked at the subject in its proper aspect.

It has been thought by many that the violent excitement which has prevailed in regard to trees, has been the means of stocking the country with these valuable plants to a degree which would not otherwise have occurred: that many who are disappointed in the sale of

trees which they have on hand, will necessarily turn their attention to the production of silk; and that in this way the effects of the speculation will ultimately be good. We are not sanguine in this opinion. The effect may be in some cases what is here suggested; but on the other hand, the gross and extravagant inflation of prices, and the frauds and deceptions which have been practised, and the numberless lawsuits which are every where growing out of these mulberry contracts, and the disappointments and losses which many have suffered, have created such a general and strong disgust, that men will fail to make any just discrimination, and condemn the whole subject in the gross.

In spite of all this, we repeat our firm belief that the production of silk is destined to become a common and profitable branch of agriculture among us. We do not look forward to the extravagant and enormous profits and returns upon which some persons have based their calculations; but we believe that it will yield a fair compensation for the labor that it will require; and that there is in many families and situations a kind of labor which may be applied to the production of silk, which cannot be, or is not likely to be, applied to any thing else; in this case the product, let it be more or less, will be a gain. The extraordinary revulsions which have taken place in the prices of mulberry trees, revulsions, it is believed, more extraordinary than have ever occurred in respect to any thing else, need not discourage us; but as the low price of trees will put it into the power of every one to obtain a supply at the most trifling cost, or at no cost whatever, a new facility is added in making an experiment, which if pursued with care, skill, and reasonable expectations we cannot have a doubt will be entirely successful.

To the Commissioner's Third Report of the Agriculture of Massachusetts is appended a table detailing every step in the improved methods of silk culture tried and approved by Beauvais. We invite the particular attention of our friends to this curious and ingenious document, which will be found of inestimable value. H. C.

MASSACHUSETTS SOCIETY'S PREMIUMS.

The prospectus of the Massachusetts Agricultural Society's premiums for the current year, we had intended to make the subject of particular remark; but we must express our regret that an accident has put the only copy we had out of our possession; and, away from home, we cannot supply the deficiency.

We can only renew the entreaty upon all our agricultural friends in the State to do all they can to circulate this document, and to induce an extended competition for the magnificent prizes which are offered, especially for the best cultivated and improved farms. The terms on which the competitor is admitted are as liberal as could be asked. The last year there were but four competitors. One of these was a very deserving farmer, who had twice before swept a portion of the stakes. Our was a farmer, who received last year out a premium but a gratuity, which seems to have been given rather to encourage application than to reward any extraordinary skill or success. Now we beg of our brother farmers to wake up and bestir themselves. There ought in Massachusetts to be instead of four, at least one hundred competitors; and we think we should have no great difficulty in naming a large portion of the hundred, who need not hesitate on any grounds to enter the lists.

We observed with the highest pleasure that two or three splendid premiums are proposed upon the best ploughs, which may be presented at a fixed time and place to be hereafter designated, and their good qualities fully tested. We are exceedingly gratified that this competition is to be opened to the whole country; and

we hope the competitors will come in crowds from the east and the west, the north and the south. Let us see what can be done. Let Massachusetts be beaten if she deserves to be beaten; for any such defeat will only prove with her intelligent farmers and mechanics the incentive to higher improvement and excellence.

We have seen with much regret, occasional remarks in some of our agricultural journals, disparaging the efforts or assuming to censure the supposed negligence of the Trustees of the Massachusetts Society for the Promotion of Agriculture. Nothing can be more unjust than such remarks; and we are persuaded that they can have arisen only from ignorance of the facts in the case. We have not deemed it either necessary or expedient to volunteer any defence in the case. They require no defence. The Massachusetts Society was instituted more than forty-five years ago. Its institution was the offspring of public spirit, and its funds were mainly the offerings of private and patriotic liberality. The State in regard to its endowments, has placed them upon the same foundation as other societies in the Commonwealth. They have published ten volumes of most valuable papers for gratuitous distribution; and given to the public annually many valuable papers and reports in other forms. They held cattle shows and ploughing matches for many years in succession while the public interest rendered them useful; they have husbanded the funds of the society in the most useful, and distributed them in the most judicious manner; and without fee or reward, they have labored and continue to labor by their disinterested efforts for the improvement of the agriculture of Massachusetts. We do not believe that any society of any kind among us in proportion to their means of action, has ever effected a greater amount of good, or continued to labor with more efficiency. H. C.

PLANTING POTATOES IN THE FURROW.

A very skillful and experienced farmer stated to me what I think well worth remembering. In planting potatoes, which he always does by the plough, he does not lay the sets in the bottom of the furrow and then turn the land upon them, because this would bury them much too deep; but, turning his furrow at an angle of 45°, he lays the set just on the inverted furrow slice, so that the next furrow slice shall in lapping cover the potato only about an inch in depth. This is very judicious. Potatoes should not be planted deep, but cultivated as near the top of the ground as can be without being out of the ground. H. C.

ROSE BUSH SLUG.

We would call the attention of amateurs and florists to the liberal premium offered below by Thomas Lee, Esq and the Mass. Horticultural Society, for the most successful method of destroying the rose bush slug—an insect which has been a serious impediment in many places to the successful cultivation of this queen of flowers. Mr Lee has set an example in this and in repeated instances, worthy the imitation of those who have a little surplus capital to spare. A few thousand dollars offered in premiums for the most effectual methods of destroying the voracious insects which prey upon the products of the garden and field, would set the wits of the Yankees to work to find a remedy, and might prove a great benefit to the community. J. B.

NOTICE.

At a meeting of the Mass. Horticultural Society held March 7, 1840, Thomas Lee, Esq. offered a premium of ten dollars for the most successful mode of destroying the slug which infests the rose bush, and on motion of Mr Downer, an equal sum of money was offered by the Society for the same purpose, for the ensuing year; the whole to be under the direction of the Committee on Flowers.

Attest,

E. M. RICHARDS, Rec. Sec'y.

Massachusetts Horticultural Society.

EXHIBITION OF FLOWERS.

Saturday, May 23d, 1840.

By Thomas Lee, Brookline; fine specimens of white Noisette rose; Clarkea pulchella, var. alba and purpurea, with other fine annuals, grown in the green house; Rexia Virginia, handsome indigenous perennial.

By Messrs Winspiss; Lonicera Caucasian, or upright Caucasian Honeysuckle; a very beautiful shrub with white flowers, which we would recommend to every cultivator.

By William Kenrick; handsome bouquets, including Peonys and other fine flowers: good specimens of Wisteria conopsea.

By John Hovey, Roxbury; bouquets.

Wm. Meller, Roxbury, exhibited some fine pansies; among them a few specimens very good; also a fine collection of Geraniums in pots for premium.

By Joseph Breck & Co.; Dodecatheon media, var. alba and purpurea; Phlox divaricata and stolonifera; Trollius European; Lychness floscuuli; pansies of various sorts.

Samuel R. Johnson exhibited one dozen fine tulips for premium. A. Bowditch exhibited a large collection of Geraniums in pots for premium.

Samuel Walker, Roxbury, made a superb display with his pansies, including some new and very fine specimens; also one dozen very fine tulips for premium.

A variety of indigenous flowers by some person unknown. For the Committee,

JOSEPH BRECK.

AWARD OF PREMIUMS.

The following premiums offered by the Mass. Horticultural Society, were this day awarded by the undersigned:

Tulips; first prize to Mr S. Walker; second do to S. R. Johnson. D. HAGGERSTON, WM. MELLER, Judges.

Violas: the best twelve, Mr S. Walker; best six do Mr W. Meller; best seedling, Mr Walker. S. JOHNSON, D. HAGGERSTON, Judges.

Geraniums: the best six plants in bloom, Mr A. Bowditch; second best six do Mr William Meller. D. HAGGERSTON, J. BRECK, Judges.

May 23.

BRIGHTON MARKET.—MONDAY, May 25, 1840.

Reported for the New England Farmer.

At Market 200 Beef Cattle, 10 pairs Working Oxen, 15 Cows and Calves, 120 Sheep and 950 Swine. 45 Beef Cattle remain unsold.

PRICES.—Beef Cattle.—The prices obtained last week for a like quality were not sustained. We quote a few extra, \$7 50. First quality, \$7 00 a \$7 25. Second quality, \$6 50 a \$7 00. Third quality, \$6 00 a \$6 50.

Working Oxen.—No sales noticed.

Cows and Calves.—\$35, \$25, \$32, \$35, and \$42.

Sheep.—Lots were sold at \$2 00, \$2 35, and \$2 42. Swine.—Lots to peddle, 5 for sows, and 6 for barrows. Small pigs 7. Large hogs 4 1-2 a 5 1-2. At retail from 5 to 7.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending May 24.

May, 1840. | 7 A.M. | 12 M. | 5 P.M. | Wind.

LUKE FOR MARE.

150 Casks Luke, partially damaged, will be sold low by the subscribers, at No. 30 Sea Street, Boston. May 20; 3w SOLOMON PIPER & CO.

WALKER'S SPLENDID TULIPS

Are now open for exhibition, at the Public Garden, foot of Beacon Street, and will continue for several days.

Since the last exhibition, great additions and improvements have been made. The bed, the present season, will contain upwards of 4000 Bulbs, all of them rare, and the Flowers very beautiful; among them will be found several varieties that obtained the Queen of England's Plate Prize, at Hampton, in May, 1838.

A suitable House, 120 feet long, by 18 feet wide, to compare with the dimensions of the Bed (which is double the usual size) has been erected by the Trustees of the Garden, and all the arrangements have been made with reference to the gratification of the Public.

Admission to the Tulips, Garden, and the Conservatory, 125 cents.

Open every day, (Sundays excepted) from sunrise until sunset. May 16.

SCYTHES, RAKES, &c.

The subscribers offer for sale a very extensive and complete assortment of Scythes, Rakes, &c., consisting in part of 300 dozen Phillips, Messer and Colby's superior Scythes,

- 50 " Metcalf's do. do.
- 50 " Tall's cast steel do. do.
- 25 " English do. do. Grass do.
- 10 " do. do. do. Cradle do.
- 10 " do. do. do. Border do.
- 100 " Hall's Rakes, superior.
- 100 " Wilder & Eddy's do. do.
- 200 " Common do. do.
- 100 " Clapp's patent Scythe Smiths.
- 50 " Baker's do. do. do.
- 100 " Common do. do. do.
- 2500 " Austin's superior Rifles do.
- 2000 " Common do.
- 1000 " Scythes Stones.
- 100 " Grain Cradles superior.

They would respectfully call the attention of Dealers and Agriculturists to the above assortment, which consists of many of the best kinds now in use, and which they are prepared to sell at the very lowest prices.

JOSEPH BRECK & CO.

New England Agricultural Warehouse and Seed Store, 51 & 52 North Market Street.

May 20.

FOR SALE.

For sale a fine heifer calf, from one of the best cows in the county, and by the celebrated Ayrshire hull imported by Mr Cushing. Inquire at this office, or at Wmshus' establishment at England. May 20.

FINE DOUBLE DABLIES.

For sale by JOSEPH BRECK & CO. No. 52 North Market Street, at reduced prices, a splendid collection of Double Dablies. May 20.

CARNATION SEED.

The Subscribers have received from Rotterdam, a small quantity of extra fine Carnation Seed, saved from one hundred choice varieties, which they offer at 25 cents per paper. We have tried it, and find that it vegetates freely. It cost us 30 guilders per ounce, and from the representation made, no doubt will give satisfaction to those who may be disposed to try it. We have also very fine carnation seed at 125 cents per paper. The seed may be sown with good success any time in May or June. JOSEPH BRECK & CO. May 20.

GARDENERS KNIVES.

JOSEPH BRECK & CO. have this season imported and now offer for sale a few very superior Garden Knives, for pruning, &c. manufactured expressly for Gardeners, and warranted superior to any article of the kind before imported.

Also—a large assortment of Budding Knives, Grape Scissors, &c. &c. April 22.

PURE BLOODED STOCK.

For sale three young Bulls 7 to 9 months old, from improved shorn horn Durham, Alderney, and North Devon Stock. Inquire at this office. April 29 6t

HORTICULTURAL TOOL CHESTS.

Containing a complete set of Garden tools of superior finish and style, recently received from Liverpool and for sale at the New England Agricultural Warehouse and Seed Store. May 6.

THE BOY'S COUNTRY BOOK

Of amusements, pleasures and pursuits, illustrated with 22 original designs. By WILLIAM HOWITT. One of the best books for lads ever published. For sale by April 29. JOSEPH BRECK & CO.

(Continued from page 390.)

Near the junction of the Juniata, the rock becomes slaty and of less dip, say about 50° or 60°; the wood is small and stunted, and we began to see hemlock and pine. At Donkinsville, just above the junction of the canal forks, one branch continuing up the Susquehanna to Wilksbarre and the coal mines, and the other branch passing up the Juniata valley, and distinguished by the name of the Juniata canal, we crossed the Susquehanna by means of a bridge which is built upon eleven stone piers, leaving two tow paths, the one above the other, so that boats may pass each other here with the same facility as elsewhere. A little above this place we crossed the Juniata by an aqueduct. Twenty miles from Harrisburg we came to the little town called Newport.

Beyond Newport the strata of rocks appeared to dip to the N. W. with a very large angle. Millers-town, 40 miles from Harrisburg, on the north side of the river, is a very pleasant town, and there are some excellent and well cultivated farms. A few miles below this place we were ferried across the river in a novel manner. An endless rope is stretched across and passed over a wheel at each side; the horses are driven upon a flat boat, a line from which is attached to the endless rope; the wheels are then put in motion by a mill, which is supplied with water from a lock above. After leaving Millers-town we made a great turn to the S. W.; the hills on the northerly side recede from the river, making a valley of considerable width of cultivable land, but the soil appears to be lighter than it is below and is rather stony. I shall long remember the first night that I passed upon the canal. The evening was delightful, and we sat upon the deck watching the changing scenery until 9 o'clock. The moon shone brightly and lit up the landscape with a mellow light; the merry song of the driver, the horn of our boatman as we approached the locks, and the answering notes of bugles from descending boats, added to the wild beauties of the scene, brought to my mind Scott's descriptions of highland scenes with something of reality. After going below, the captain called over the names of the passengers, and according to custom, those whose names are first upon the waybill, have the choice of berths, and when the passengers are numerous, it is no small advantage to have engaged your passage early.

When I awoke in the morning of the second day, we were in a broad valley extending far to the left; on the right was a perpendicular wall of red sandstone of a slaty structure, the strata nearly horizontal, and I observed several upheaves which presented the appearance of regular arches. The soil here is more gravelly and there is more wet meadow than I observed in the valleys that we saw yesterday. Waynesburg, 75 miles from Harrisburg, is situated in a broad rolling valley. The farms in this vicinity appear to be well cultivated, having fine fields of clover and orchards, and the rich pastures were well stocked with fine cattle and horses. In this region I observed considerable quantities of iron ore. At 11 o'clock we passed Hamiltonville, a thriving little village. At this place we turned south and made a sweep around the base of a high mountain, a distance of five miles to gain three quarters of a mile, describing almost a circle. The rock here I took to be limestone, on account of the shells that I observed in it, but I had no opportunity to examine it particularly. We crossed the

river several times to-day in aqueducts. In the afternoon of this day we arrived at Huntingdon and stopped a short time. This town contains a score or more of houses, and makes a poor appearance, though it is said to be a place of considerable business, and is in the centre of a good farming county.

After leaving Huntingdon the country assumes a rough appearance, the strata of rock are nearly perpendicular: the faces of the mountains look as if they had been furrowed deep by the action of water, leaving sharp ragged peaks of naked grey rock, some of them of great height. A few miles from Huntingdon we entered a piece of slack water, three miles in length. These slack water levels are formed by building a dam across the river, and the boats are let into it by means of a lock. Advantage is always taken of every convenient place to convert the river into a slack water level, because the greater depth and width of water is more favorable to the progress of the boats than the ordinary canal. Passed Petersburg and Alexandria, both inferior towns.

The next morning we were in a broad valley of rather wet, marshy soil—passed Franktown, a considerable village, and at 7 o'clock came to Holidaysburg, a smart town of about 100 houses, many of them brick. This is the termination of the Juniata canal. Between this place and Huntingdon there are 42 locks, and in the whole distance from Harrisburg about 100, each lifting from 6 to 14 feet, and the total lockage I judged to be about 1000 ft. As we took the cars at the canal basin immediately, we had no time to look about town

(To be continued.)

Anecdote of Roger Minot Sherman.—Many years ago, while the legal reputation of Roger Minot Sherman was yet in its infancy, and he himself a young man of twentythree, he was a resident of Norwalk, Connecticut. He had been a member of the State Senate, and was very highly respected; but the party adverse to him in politics, suddenly gained the ascendancy, and determined to bring him down a peg or two.

A town meeting was to be held, and town officers to be appointed; among whose number, in old Connecticut, is an official personage designated a *Hog-hayward*. The duties of this dignitary are not exactly synonymous with those of the *'High-ager'* of the State of New Jersey, (whose business is to take the curls out of pigs' tails,) but are much more responsible, though perhaps hardly as laborious.—The hog-hayward's duties are to 'captivate' all stray pigs, put rings in their noses, and imprison them in the village pound. To this high office, his enemies resolved to elevate Mr Sherman. The town meeting convened, despatched its other business, and came to the election of petty officers, at the tail of which list stands the officer we speak of.

'Gentlemen,' said the moderator, 'please to nominate for hog-hayward.'

'Roger Minot Sherman!' exclaimed half-a-dozen voices. The moderator being a worthy man, was somewhat amazed; but could do no less than put it to vote, by requesting 'those in favor of the nomination to hold up their right hands.'

The majority of elevated hands was overwhelming, but the moderator felt inclined to give the matter the go-by, and said it was 'not a vote.'

The voters immediately clamored for a division of the house. Mr Sherman, who had remained quietly seated in a corner, now rose, and with great

frankness said: 'Mr Moderator, this seems to me most decidedly to be a vote; but, nevertheless, I would thank you to allow the house to divide, in order to show me how many hogs I shall have to take charge of!'

SILK WORMS EGGS.

Just received, a few ounces of Silk Worms Eggs, from Smyrna, said to be of a superior variety. Price 88 per ounce, clean seed. JOSEPH BRECK & CO.

April 1.

SINA SILK WORMS EGGS.

The Eggs of the celebrated Sina Silk Worm, now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The Sina Silk Worm was introduced to France from China by Louis XVI. in 1783, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France. Each sheet contains an ounce and is signed 'Camille Beauvais.' Price 88.

WILLIAM KENBICK, Newton.

WANDERINGS IN THE WEST IN 1836.

No. II.

(Continued from page 336.)

The Allegheny portage railroad crosses the highest ridge of the mountains, and is 36 miles in length. There are five inclined planes ascending and the same number descending, and at each there are a stationary engine. The cars are drawn over the short levels intervening by horses and over the summit by a locomotive. Near the termination of the railroad on the west side of the mountain, we passed through a tunnel perforated through the solid rock, 1400 feet in length.

The mountain is of red sandstone, and generally the strata are nearly horizontal. It contains an inexhaustible amount of bituminous coal, which is exposed to view in many places by excavations for the railroad. The scenery surpasses my power of description. It is at once, and in a high degree, wild, picturesque, and grand. The mind of the beholder is excited rather than pleased.

At 2 o'clock we arrived at the canal basin in Johnstown. This town is situated in a deep glen surrounded by high mountains, and has the appearance of a busy little place. We went immediately on board the canal packet and soon left town. The canal passes down the valley of the Conemaugh, and is fed by that river. The scenery is romantic and beautiful. The soil of Pennsylvania where it admits of cultivation, is generally very rich and of a peculiar reddish color, which is probably owing chiefly to the decomposed sandstone of the mountains.

The morning of the fourth day I saw saltworks on the bank of the river. The water is obtained by boring to the depth of 150 or 200 feet. It is pumped up by steam power and is evaporated by boiling. The fuel used is bituminous coal, which is dug out of the mountains in the immediate vicinity, a coal mine or *digging* being connected with every salt-house.

The salt which is manufactured here is not of the best quality. It is damp and is tinged with the color of the soil. We passed Saltsburg, a ragged little hamlet, which derives its name from its manufacture: this is 63 miles from Pittsburg. Seven miles below, we passed extensive saltworks and coal mines: the soil in this vicinity is thin and sterile: the river is here called the Kiski mits. Five miles below we passed Warrenton, another ragged little village. Vegetation on the west side of the mountains, for a very considerable distance, appeared to be a week later than on the east side. Among the plants that were new to me, was the tulip tree, a species of poplar, bearing flowers of a light straw color, and nearly of the size and shape of tulips—hence its name. The first tree of the kind that I saw was in Washington square in Philadelphia. In the mountain valleys they grow extremely large: the leaf resembles the sycamore leaf. At half past ten we came to Leechburg, 36 miles from Pittsburg, and at noon to Freeport, in

Armstrong county, where are several mills, three churches, and there is the appearance of considerable business. This is a short distance below the junction of the Allegheny river. The scenery now becomes quite changed: instead of high mountains on either side, we see rich, well cultivated farms. Five miles from Pittsburg we passed Tarentum, a very neat town, and at 7 o'clock we arrived in the city.

Pittsburg is seen to good advantage from the canal. The immediate vicinity is very beautiful. The city itself is compactly built and is a place of very extensive business for its size: the manufacture of iron in particular is carried to a great extent, and its situation at the head of steamboat navigation, gives it very important commercial advantages.—The people are shrewd, enterprising and active; and in consequence of these qualities, there are many who have become quite rich and are beginning to exhibit the pride of wealth in elegant mansions, carriages, &c.

Alleghanytown is a pleasant place and is gaining rapidly. Many of the wealthy Pittsburgers have their residence in Alleghanytown, to avoid the noise and bustle of the city, as well as the smoke, which in certain states of the atmosphere is very annoying, and at all times is rather disagreeable. There, also, Mr Stone, a native of Massachusetts, has by his own unaided exertions, established a classical school for boys, and I was glad to find that he is patronised according to his merits. Whatever a highly cultivated mind, indefatigable industry and exemplary virtue will enable one to do towards training through scholars and forming correct habits, will be done by Mr Stone, and his school will prove a lasting benefit to that section of the country.

During my stay at Pittsburg nothing appeared to me so peculiar and foreign as the common accent and phraseology of the people. Something like an Irish accent is common, and the pronunciation of *ing* like *n*—thus, *lie'n, cat'n, &c.*; the objective for the nominative in phrases like this—*them's the best: like for us*, and the frequent use of *just*, are some of the peculiarities of speech that distinguish a western from an eastern man.

There is no dependence to be placed upon the word of the captains of the steamboats at Pittsburg with regard to the time of sailing. They will advertise for tomorrow or today, when they do not intend to go for a week, and will assure you positively that theirs will be the first boat to go, and will even get up steam in order to make an appearance of starting, when they intend no such thing. The best way is to inquire of some resident who is acquainted with the boats, who can judge from the time that the boats have been in, and other circumstances known to him, which boat will go first and can recommend you to the best. One afternoon I put my baggage on board the *Wm Penn*, which was advertised for the next morning at 10 o'clock, and the next morning I went down to the landing accompanied by a friend, and found that the boat was not ready, and notwithstanding the captain's promises, I was persuaded that he would not go un-

til the next week, this being Saturday. Accordingly I took out my baggage, though not without opposition, and put it on board the *Mame*, which was getting up her steam, and at 2 o'clock we left Pittsburg.

The steamers upon the river are very neat, and commodious, but more frail in their construction than those upon the sea-board. The scenery below Pittsburg is very beautiful. At 3 o'clock we passed Economy, a little town which was settled by Rappe and his associates. A little below is Freedom, a pleasant little town; then we came to Beavertown, and 19 miles from Pittsburg brought us to Wellsville, where we stopped for passengers. About dark we came to Steubenville, a smart thriving town, where we stopped an hour.

When I awoke on Sunday morning, we were 20 miles below Wheeling. The banks are bold and rise back into high thick-wooded hills, and where sections are uncovered, red sandstone and coal are exposed. At about 19 o'clock we passed Marietta, at the mouth of the Muskingum. This town is delightfully situated and well built, and shows to good advantage from the river. When we were passing, the church-bell was ringing for morning service; the stores were closed, and the town had a quiet, orderly air, which reminded me of New England, and I should have been pleased could I have stopped there. Marietta is 81 miles below Wheeling. Thirteen miles more brought us to Parkersburg, a pretty town on the Virginia side.

Three miles below Parkersburg we came to Blennerhassett's island, a place memorable in our country's history for being the scene of Burr's conspiracy. This island is three miles long and contains from 300 to 500 acres, mostly under cultivation: there are some fine orchards upon it, and two farm houses, but the mansion is in ruins.

As we pass down the river the hills are less bold and the soil everywhere appears to be very rich.

About sunset we passed Point Pleasant, at the mouth of the Kanawha, 262 miles from Pittsburg. The rays of the setting sun seemed to gild the little village, and having a fine situation, it appeared very beautiful indeed. Two miles below stands Galpolis, also a pleasant village.

Monday morning we came to Portsmouth, near the mouth of the Scioto, 115 miles above Cincinnati. This town is built upon a high bluff and makes a handsome show of good buildings. The facade of the principal street next to the river is very fine. The bluff has been sloped from the street to the water's edge to make a convenient landing, and it also adds to the beauty of the place. We left Portsmouth in the midst of a fierce thunder storm, which drove the passengers into the cabin.

The Ohio river is studded with numerous beautiful islands, which are generally cultivated in the middle and have a border of timber on the declivity next to the water; the upper ends terminate in long flat sand bars, and the lower ends are abrupt.

This forenoon we came up with the steamer *Dolphin*. These boats had passed and repassed several times coming down the river, and now it was evident that both captains intended a race. Both

got up a heavy steam, and both boats were apparently put to their utmost speed. The Dolphin was just ahead, and the boats dashed through the water like two generous steeds, snorting and galloping furiously as they bear their gallant riders proudly over the battle field. For about an hour the excitement was great,—every person appeared to be interested. At length the Maine got up abreast and was gaining upon her rival, when having reached Maysville, we hauled in to leave passengers and freight, and the Dolphin went on her way and was soon out of sight.

(Continued on page 401.)

For the New England Farmer.

ON THE CURCULIO.

MR EDITOR.—Sir—It is less than one year since I have been a reader of your valuable agricultural paper: I consider it valuable as a farmer's paper, because I consider the agricultural interest the most important interest of our country, and in fact almost the only means whereby the country is to be enriched and made prosperous. Cleg this great wheel, and every other wheel is retarded. And I consider that every particle of useful knowledge or information that is given, adds something to the general prosperity. I have been told that your paper was a valuable one for the farmer: so it is, and I think valuable to every member of the community also; for there are thousands in the country who are not farmers, but might contribute their mite to the diffusion of useful agricultural knowledge.

I have read several communications on insects, viz: the borer, the yellow cucumber bug, the curculio, and their genealogy, their ravages, and experimental remedies, though many of them do not prove to be successful. The curculio is the insect on which I shall attempt to write what my own observation teaches me, in plain homespun English, and hardly that, for I never received an education, and cannot grace my story with terms from borrowed language—nor would I do it if I could, for I have not a very exalted idea of a master's pretending to teach a pupil in language he cannot understand himself.

Of this curculio, or beetle, as it is termed, I have some eight or ten at this time, in the chrysalis state. I would here observe that I consider them to have three stages of existence: the first I shall call the worm in the fruit. In this state they remain from the time the egg is deposited in the fruit in July, up to this time, and something later. I have them in the chrysalis at this time, but they do not get into the ground, and I think Dr Thatcher putting them in the ground in his cellar, to be the reason they did not arrive to the perfect stage.

The second stage takes place between this time and the middle of June: in this state they are enveloped in a case of shelly covering: this state I term a state of embryo, in which they remain but a short time.

The third and next is the perfect state, in which they appear in the shape of a moth or miller; when they are ready in July again to commit their depredations.

Now how shall we get rid of them, is the question, and I cannot answer it. But sure I am they do not go to the ground—they do not leave the tree, other than those that leave in the fruit; but you will find them concealed under bark cracks, where limbs have been cut off, and in decayed spots in the trunks, if there be any; and they can be found

there in the spring, exactly the same insect as when it inhabited the apple, and can travel off as sprightly, get again in some crevice, and wind a web around itself again. I do not know how wholly to destroy them, as they can fly from tree to tree or from orchard to orchard. I have experimented on them for two or three years, and am satisfied what they are. If any one should wish to test what has been said with regard to the curculio, as it is called, they may obtain thousands of them by winding round or hanging any old cloth in the crotch of the trees, from the time they begin to leave the apple till the time the fruit is gathered. I think at present the best remedy would be this: In the fall, when the insect has crept into the cloth for winter quarters, take the cloth from the trees and put it into an oven hot enough to destroy them.

Mr Editor, if what I have said can be wrought into any thing beneficial to our agricultural community, it will be a satisfaction to

Your most obt. serv't.

JOSEPH BURELLE.

Quincy, 8th April, 1840.

CONNECTICUT RIVER FARMING.

We are very happy in presenting to our readers the subjoined account of his farming from one of the most practical and successful cultivators in the highly improved part of the State in which he resides. The extracts from his communication, which are subjoined, follow a part of the same letter relating to the cultivation of wheat which is given in the appendix under the head C, in the Third Report of the Agriculture of Massachusetts. We beg leave to say, that we shall hold our friend to his promise and shall be happy to hear from him as often as his convenience permits him to communicate to us the valuable and interesting results of his observation and experience.

H. C.

TO HENRY COLMAN, & C. & C.—Sir—Did I not fear I had already intruded on your patience, I would say a few words more about my experience in farming. The farm I occupy is a part of a farm my father formerly occupied. He used to practice the old-fashioned way of planting one year and sowing oats the next; then planting again. My practice is different. The above course has a tendency to exhaust land. My method is, to plant corn and potatoes, then sow wheat or oats, and seed with grass. In this way I have green crops to turn under every year, and under this course my land is constantly growing better. I think that in the last fifteen years I have tripled the product of my farm. I did not think a few years since I could raise more than two hundred bushels of corn: the last year I have raised six hundred, bc. 600.

Formerly but little or no wheat; the last year 346 3/4
And about two hundred and fifty of rye 250

Making (of grain) 1196 3/4
One hundred and ninety of potatoes 190
and all from about forty acres of land. I do not speak of this as a great yield—still it is a great yield to what we formerly got from the same number of acres. The same land is capable of still greater improvement and of producing one-third more than it now produces.

I keep over the summer from six to eight hogs and eight to ten pigs; from these I make one hun-

dred loads of good manure annually; this I think will pay all the expenses of their keeping until I put them up for fattening. Farmers generally might make double the manure with their hogs by only supplying them with muck, turf and leaves. In fact, hogs will convert almost anything into manure which you will give them.

One word about corn, as this is our greatest crop on the Connecticut River. We ought to search for that kind which is best adapted to our soil. I have tried many kinds since 1836; previous to that time I used the old large meadow corn, but that wants a long season; and for the two last years I have had as good success with the Dutton corn as any I have tried. The way I manage my corn is, I never plough my greensward until I get ready to plant; for two reasons, the grass, by not ploughing until May, will get up and be almost as good as a coat of manure; and another is, the worms will live on the grass, and thereby prevent a great deal of damage which they frequently do. I have entirely done ploughing sward land in the fall. I am satisfied it is a bad practice. When I get ready to plant I turn under my green sward and roll it down with a good roller; this I think indispensable. Had I not extended these remarks to a great length, I would relate my experience in the roller the last year. I planted a field of fourteen acres; we had ploughed and planted about two-fifths of the field when my brother began; and he owned a roller with me and he sent for it when we had planted as above stated; his field lying about one mile from mine we concluded to dispense with the roller and use the harrow on the remainder of the field, and, sir, it is a fact that the part of the field that was rolled was not as good land as the part harrowed and the manure as near alike as could be. The part rolled, after weeding, got the start of the part harrowed, and many will testify that the first of July the corn where the land was rolled was one quarter heavier, and continued to be so through the season, than the part harrowed. I want my land turned over as flat as can be.

In the application of manure, I always overhaul my manure early in the spring, and mix with it some lime, gypsum and sometimes wood ashes, and by the time I want to plant it is nearly all rotten. I plough under my long or green manure, and my compost sometimes put in the hill and sometimes spread on after ploughing and harrow it in. The latter mode I think is generally the best, as there will not be as many suckers to corn where you put in the hill. In hoeing I never put a plough in my corn, believing it to be injurious to the roots. I harrow my corn the two first hoeings and the last time generally hoe plain—making no hills—leaving the ground as level as I conveniently can.

Finally, I believe if farmers would attend more to making manure and also improving the condition of their land by turning under green crops, we should see as great crops as they raise in the Western States on our hard New England soil.

Now, sir, you are at liberty to set aside such portions of these remarks as you please, and make such use of the remainder as you please;—coming from a Connecticut River farmer's pen, you cannot expect anything great.

Respectfully yours,

ZEBINA STEBBINS.

Employment is one of the best remedies for the disappointments of life.

For the New England Farmer

PROPER TIME FOR PRUNING FRUIT TREES.

MR. EDITOR:—Observing in several agricultural journals, queries respecting the proper time for pruning fruit trees, I wish to offer, through your valuable paper, the result of my experience on this subject, about which there is much diversity of opinion.

I have more than three hundred fruit trees on my farm, the growth of which I note with somewhat of the interest and pleasure of a parent watching the progress of his children. Some of these trees are young, and others are in full bearing, and I have pruned them at different periods, to learn by experience the best time. I am decidedly of opinion, that the last week in June is the very best time for pruning. I have made the experiment of pruning the same tree in May and June. The wound made by amputation of the limb at the close of June, healed much more rapidly than that made in May. This experiment I have repeated till I am confident that the latter part of June is the proper time for pruning fruit trees. I made the experiment because of the various and even contradictory opinions of writers on this subject, some of whom could never have enhanced the value of their opinions by first subjecting them to the test of experience.

Perhaps it will be asked, why should the time proposed be a more fit time than April, or May, or any other month? The answer is, it is well known to the student of vegetable physiology, that the sap in trees flows so slowly for a short period after the close of the longest days in June, that it may be said to be stationary, and therefore, when a limb is taken off at this period, the sap pours out slowly and remains around the orifice of the wounded bark, forming a cicatrice of a rapid growth. If you remove a limb early in the season, April if you please, the wound heals slowly and the tree is injured, and why? Because in the opening Spring the sap flows in so rapid a current that it forces itself out at the wound, runs down the tree, and thus seriously injures, and perhaps destroys it. All this injury to the tree is avoided by pruning the last week in June, because, as I before said, at this period the sap is almost stationary.

Some of your readers may say, I have pruned my trees at such, or such a time, and they have done very well, and therefore it is not material when we prune. But, Mr Editor, this only proves how nature will survive all our mangling and marring her beautiful works, and continue to pour out to us her bounties, after all our neglect, or injurious interference. We should study her operations and learn her laws by careful and long continued observation; and when we have learned them, we should mould our opinions and conform our practice to them.

D. P. W.

Dedham, May 22, 1840.

PLYMOUTH AGRICULTURAL SOCIETY.

REPORT ON INVENTIONS.

We award to Fobes, Crane & Co. of West Bridgewater, for an improvement on Cooking Stove, \$5, and 1 vol. New England Farmer.

To John A. Conant 2d, of East Bridgewater, for an improved Leather Roller, \$4, and 1 vol. N. E. Farmer.

To William Turner of Bridgewater, for Corn Sheller, \$1, and 1 vol. Yankee Farmer.

To George W. Pratt of Bridgewater, for a new constructed Straw Gauge, \$1.

To Jonathan Whipple, of Grafton, Leather Cutter, \$2.

To Sproat & Andrews, for a Patent Board Saw Reliever, \$3.

To Seth Pratt, Jr. of Bridgewater, for a Bugle, \$2.

Most of the articles are in a highly finished state, and give evidence of increased improvement in the mechanic arts. The bugle, by Mr Pratt, we consider, though we are no musicians, to be particularly an article of superior workmanship.

All of which is submitted,

SOLOMON HAYWARD,

Per Order.

REPORT ON FRUITS.

To George Thompson, Middleboro', for a fine head of Cauliflower, \$1 00

" Abram Washburn 2d, Bridgewater, a sample of large Rohan Potatoes, (having raised from 3 lbs. of seed, 720 lbs. of potatoes, 2 00

" Abram Washburn, Bridgewater, for large Squashes, (having raised 595 lbs. from 1 seed, 2 00

" William Smith, East Bridgewater, for Squashes, 2 00

(He received 21 seeds from Providence, from which he raised nearly a ton of squashes. The acorn squash was the variety.)

" Sylvanus Barrow, Middleboro', for large Squashes, (the largest weighed 91 lbs.) 3 00

Respectfully submitted,

A. COLLAMORE.

CHOPPING HAY.

The following is a statement of BENJAMIN HALE, proprietor of a line of stages running between Boston and Newburyport. It is a correct statement of the saving made by the use of Straw Cutters in preparing the feed for his horses.

"The whole amount of hay purchased from April 1, to Oct. 1, 1836, (six months,) and used at
Tons cwt. qrs. lbs. 32 4 0 00

At \$25 per ton, (the lowest price at which hay was purchased in 1836.) \$800 00

From Oct. 1, 1836, to April 1, 1837, whole amount of hay and straw purchased for, and consumed by the same number of horses, viz:

Tons cwt. qrs. lbs.	Cost.
Straw, 11 13 3 10	\$160 22
Hay, 13 11 1 60	35 00
	<u>\$510 22</u>

Deduct on hand, April 1, 1837, by estimation, four tons more than there was Oct. 1, 1836, at \$25 per ton, \$100 00

Saving by the use of Straw Cutter, four months of the last six months, or the difference in expense in feeding with cut fodder, and that which is uncut, 389 77

Whole amount of hay used for

the horses of the Salem stage, twenty five in number, from April 1, to Oct. 1, 1836, viz: 22 0 0 0
At thirty dollars per ton, (the lowest price in Salem.) \$660 00

Whole amount consumed by the same number of horses, from Oct. 1, 1836, to April 1, 1837,
Tons cwt. qrs. lbs. Cost.
Straw, 15 13 0 0 \$187 80
Hay, 2 15 0 0 81 00 268 80

Saving in using chopped fodder five months, 391 20
Total saving in using the Straw Cutter nine months, viz: at Newburyport, four months, 389 77
At Salem, five months. 391 20

Total, \$788 97

WINE.

I think if my fellow citizens would consider the great expense, risk, and uncertainty, of being supplied with wine from the usual source under the present prospect of affairs in Europe, and with what ease and trifling expense a wholesomer and better wine (if they should discard prejudice) may be made from the materials of our own country, they would use greater exertions for that purpose than heretofore: and as I have heard of many who have tried, and had their wine spoil, I will give you a brief account of my method, which has always succeeded well.

I gather the fruit when dry and full ripe, viz:—currants, gooseberries, morella, cherries, (I make no doubt but the common red pie cherries would do as well, but have not tried them,) mash them and extract the juice, using as little water as is really necessary for that purpose; then add sugar to the juice till it is agreeable to the palate. I find that a pound or pound and a half is sufficient for the tarterst fruit; when the sugar is dissolved put it in a clean sweet cask for fermentation, filling it up two or three times a day, till it discharges a clear froth, then check the fermentation gradually by putting the bung in slack; when the fermentation has nearly subsided, rack it off into a clean cask, or return it into the same, after rinsing it well with gravel, or something with the water to scour off the yeast which adheres to the inside. Before the liquor is put in, I burn a sulphur match in the cask; then put in it one or one and a half pints good apple or French brandy to a gallon, the former is best. In about a month it should be racked as before, and repeated several times in a year; and if it is left to dribble slowly each time of racking, it will facilitate its age, as, passing through the atmosphere, gives an opportunity of evaporation.—*Farmers' Cabinet*

Manure is the great agent for the increase of crops—we desire to know how we shall employ this agent to afford us the greatest yearly income. A good direction is furnished us in the maxim of a very useful agriculturist of our own time and country in this particular, which is, "to extend a given quantity of manure over as great a portion of the field cultivated as possible, so as to cause the field to yield an improved quantity of crop, the ground being left better after the crop than it was before."

For the New England Farmer.

LETTER FROM WILLIAM FOSTER, Esq.

Boston, 24th May, 1840.

MR COLMAN—I will add a few words to the concluding part of my letter of the 21st of February, printed the 15th of April. The subject under consideration was the raising of forest trees.

The reasons alleged by the experienced French agriculturist, whose practice was noticed in my letter, were—first, the very natural one, of giving the same exposition to the sun, in the new location, which the tree had enjoyed in its native bed; and not exposing its most tender and susceptible parts to the cold blasts of the north. Next it may be observed that nature furnishes the strongest roots on that side from whence the strongest winds come; and by reversing this order, weakness assumes the place where strength is required. And although nature is very fertile in her resources, in adapting herself to circumstances, both in the animal and the vegetable kingdoms, still both these patients must suffer more or less by the unskillful treatment of the doctors, and the greater or less deviation from her general laws. Aquatic plants commonly fail when transplanted to dry places; and the plants of hot climates will thrive in colder ones only by a gradual and slow education. The vine and the olive, since a period in the record of history, would hardly grow in Italy; and now the former has progressed northward, half through France and Germany; and the latter is still making progress in the same direction. The observations, above on forest trees, will be admitted, probably, as equally applicable to fruit trees. The transplanting of forest trees, on a large scale, can hardly be expected in this country, nor is it necessary, where nature has supplied us with such an abundance of them, and which require but little care, but more economy.

Wherever an incroad is about to be made into a wood lot, for the sake of the wood alone, and the owner would be willing to have a new crop of wood on the same land, I would advise—first, to mark out the space to be cleared and surround it, by felling trees on its borders, in the shape of a fence; which, with a little labor, in the winter, when labor is cheap, would be sufficient to keep out the cattle: then cut clean, or leave as many small trees only as can escape the *woolfall*. This patch will soon be covered with a thrifty growth; and all the more thrifty for the protection of the neighboring forest. I think it advisable to keep the north side of the wood-lot whole, or merely to thin it, by taking away some of its largest trees; and felling *them* northerly, so as to spare the younger growth as much as possible from the felling.

The difference between the growth of the small vegetation in places sheltered from the north winds, and that exposed to all winds, is so well understood by the gardeners in the vicinity of Boston, that they build high and expensive fences to protect their gardens. Now as Indian corn is sometimes cut off by early frosts, would it not be well to try some experiments, to ascertain the difference of time necessary to mature this grain in sheltered and unsheltered places; and at the same time to keep an account of the relative yield. If such experiments are made and published, all the attending circumstances should be related.

Assailing, clover and luzerne have, I presume, been discussed in all our agricultural papers already. The mode of using this green food may re-

quire too much labor for a country where labor is so high as in America. But it may be well to notice some of its advantages, because there may be persons with small farms and large families who might find it for their interest to practice this culture.

On the small farms in France, the practice is very general; and this is one of the means of accounting for their large products. There, luzerne and clover are cut daily, with the sickle, in quantities necessary for the daily consumption, and carried to the barnyard on horses, jacks, or in hand-carts; and more often on the backs of the laborers. The same beds may be cut several times, and thus by a proper arrangement, a daily crop is secured. As the cattle destroy as much with their feet as they eat, so much is saved by this mode of feeding, and the quantity of manure is increased, while its quality is improved. From the labor of bringing this green fodder to the cattle we must deduct that of driving the cattle to the fodder, as well as the waste of trampling: thus the apparent cost of this transportation is not the real one. Moreover, these viscous, pulpy grasses keep the ground moist, and draw much of their nourishment from the air and the dew, and warmth also from the same source, in the absence of the sun, as the thermometer would show if applied.

The choice of seed is attended to in our country I find, particularly in the case of Indian corn. But I do not know if it be so with small grain. I will therefore mention the practice in Brittany, a province of France, now called Finisterre.

During the long winter evenings the farmers spread on their tables some of the best and ripest of their small grains; and there they pick out the best grains for seed. When I first saw this slow work, I told my father-in-law that Yankees would invent some mechanical process to do this work quicker. But, said he, not so effectually, perhaps; for it requires some experience to know what *are* the best seeds. In favor of the plan, generally, he said, that a bad seed occupied as much ground and cost as much preparatory labor as a good one.

In my next I shall offer a few hints on the treatment of cider.

Respectfully, your obt^s serv^t,

WM. FOSTER.

For the N. E. Farmer.

POLITICS FOR FARMERS.

I am aware, Mr Editor, that your paper, very properly, eschews politics; and although the heading of this article would seem to promise nothing else, I will assure you that politics, in the usual sense of that word, are now the farthest from my thoughts. Good farmers cannot belong to that intriguing, idle and mischievous race called politicians; their farms, their barns, and their household require all their attention. Absence from these rural scenes and neglect of the duties they imply, would soon make them *very* fit subjects for politics indeed; for they would become embarrassed, and the fit tools for every political intrigue.

But farmers, whose whole time and talents, in conjunction with the strictest economy, are necessary for the advancement of their interest and the maintenance of their honorable station in society, have a deep interest in good government; for without *that*, their time, their talents, and their strictest economy would avail them nothing: their progress would be downward, most certainly; however slow

and imperceptible that retrograde movement might be. From independent owners of large farms, they would become independent half-owners of mortgage farms, paying taxes on land not their own. These large farms would soon pass out of their hands, and they would become tenants-at-will of small patches of land; and finally, as in the old world, merely day-laborers, under hard masters, and great monopolizers of *all* the land.

Who then has a deeper interest in good government than independent farmers? They cannot, as a body, take an active part in government, for their scattered position, although they are numerous, prevents their having the same *weight* in government as some other classes which can more easily combine: therefore, their only means of contributing towards good government is, in the choice of its agents; and this can be done only through their representatives. In the choice of these representatives, there can be no doubt that they are guided by what *seems* to be their true interest; they generally choose the best men.

Now I will conclude this short article by advising farmers, after having used all possible discretion in the choice of their representatives, to be still more particular in examining the conduct of those representatives in the performance of their legislative duties: this will be an infallible test of the goodness of their choice, and will induce them to re-elect the same men, or to replace them with others who will avoid the errors for which they should be displaced; which errors should be made as public as possible.

The errors the most fatal to the farming interest are—putting in office such men as would not obtain the suffrage of a town meeting of a virtuous, frugal, and sober community in the country; men who have not been able to conduct successfully their own private affairs; men who are *suspected*, even, of dissipation and disorderly habits in all their various forus; men who are known to grow rich on small salaries, and living at the same time better than others who have the same income; in fine, bad husbands, bad fathers, and bad neighbors; men who are too prodigal of the public treasures; for they must be replenished *directly* or *indirectly* by the farmer's labors. Farmers and mechanics may rest assured that all the expenses of State, necessary or unnecessary, come from their labors; and the greater those expenses are, the greater the drafts on their labor: the lighter those expenses are, the better is the government; and none but the best and most virtuous men will ever succeed, or even wish to establish and maintain such a government.

Now, Mr Editor, I submit it to you to say whether I have written one word which can be forced into a construction of party politics.

HONEST POLICY.

Pay as you go.—To deal for ready money only, in all the departments of domestic arrangement, is the truest economy. Ready money will always command the best and cheapest of every article of consumption, if expended with judgment; and the dealer who means to act fairly will always prefer it.

Trust not him who seems more anxious to give credit than to receive cash. He hopes to secure your custom by having a hold upon you in his books; and will make up for the credit he gives you, either by an extra price or an inferior article. Such men depend on unfair dealing for their custom.—*Farmers' Cabinet.*

RHODE ISLAND AGRICULTURE.

We have great pleasure in presenting the following account of his year's operations from one of the best farmers not in Rhode Island only, but in New England. Mr. Antony's farm does not embrace a large extent or variety of agricultural operations; but as far as it extends, it may be considered as pattern farming. Of his improvements we have spoken repeatedly before. They are skillful and beautiful, and do him the highest credit. We have only one wish in respect to him and his farm; and that is, that he was on this side of the line, that he might come in as a competitor for some of our noble State premiums. We know he has no low ambition; but an ambition to make any portion of this earth which heaven puts under our custody, as productive and beautiful as labor or skill or art can render it, is an ambition with which a generous and grateful mind may justly be satisfied. H. C.

Report of the Farm of Wm. Rotch, Jr., North Providence, Rhode Island, under the management of Adam Antony: and considerably devoted to the sale of milk in the city of Providence.

Tillage	30 acres.
English mowing	18 "
Pasture	26 "
Wood	30 "

Total 104 acres.

Soil generally dry and sandy; some redeemed peat meadow; much of the land formerly covered with pine.

Live Stock.

Horse	1
Oxen	2
Cows	18

Amount of sales in 1839 \$3294 85

Value of produce used or on hand 308 50

Labor in improvements charged to the owner 125 00

Incidental improvements on the farm, the lawful interest on which is added to the next year's rent 252 36

Cost of labor on the farm, including board 696 02

Incidental expenses 1391 04

Amount of Produce in 1839.

English hay, tons 50—average yield per acre	2 3/4 tons.
Millet, " 41	2 3/4 "
Indian corn, bush. 258	61 1/2 bush.
Barley cut for fodder, tons 10	1 3/4 ton.
Potatoes, bush. 592	236 bush.
Turnips (French) bu. 500	650 "
Swedish turnips, bushels 800	
Beef fattened, lbs. 85	
Pork, 536 "	
Corn fodder, tons 6	
Manure made, cords 100.	
" bought, ashes 1400 bushels.	

Notes by Mr. Antony.

Expense of cultivating tops per acre—	
Indian corn	\$47
Oats	24
Barley	24
Potatoes	44
Ruta baga	47
Beets	53
Carrots	59
Hay, including getting, &c.	24
Millet	21

Average yield of a cow per annum, in milk, 5383 gallons.

Beef animals fattened on hay, Indian meal, flax-seed oil meal, and vegetables.

Pork fattened on Indian meal and boiled potatoes.

Seven cords of manure were applied to an acre; and of ashes from 100 to 240 bushels.

Lime and gypsum have not been found useful.—Ashes are of great utility.

Ground oyster shells are, perhaps, good for nothing.

No difference has been perceived in the effects of fresh or spent ashes. Potash, at the rate of 150 lbs. to the acre, has been found beneficial, and the same quantity of nitre. Have tried them, however, but one year, and know nothing of the pecuniary of either.

The most profitable articles of cultivation are considered millet and clover on light and sandy soils. On such as are of a better quality and firmer texture, the root culture is perhaps the most profitable.

Considerable hay and some vegetables are sold, but much the greater part of the produce is converted into beef and milk.

ESSEX AGRICULTURE.

The following account was received by us, but unfortunately was mislaid. It has not suffered by keeping; and will be read with much pleasure. It is a fair sample of New England farming; and shows a highly productive result. Very many are who fall far below this product, over those who attain it, from the same number of acres.—Those whose imaginations and avarice are extended far beyond what is reasonable, see in such humble results as these, nothing to admire; but look with disdain upon such, in their opinion, meagre returns. Yet it is by such a process and under circumstances thus restricted, that vast numbers in New England have found not only competence but independence; and have laid the foundation, indeed have carried up the superstructure of large and ample estates. H. C.

MR. COLMAN.—Sir—I have seen in one of the N. E. Farmers that you should like to have a statement of the produce of some of our farms. My farm is in Newbury, about one mile south of Newburyport. I have about 20 acres of good tillage land, and about 15 acres of grass land too clayey for easy tillage. I have 30 acres of salt and black grass meadow; the remainder is pasture and woodland, containing in the whole about 110 acres—on which has been raised the present season 200 bushels of corn on about five acres, manured in the hill. I think that the storm of the 28th of August, destroyed one fifth of the crop. Six acres planted with potatoes, manured partly in hills and partly ploughed in, produced 1500 bushels. One acre and three quarters of onions, 740 bushels; one acre of winter rye, 26 bushels; three acres barley, 100 bushels; one acre of oats, 75 bushels; one other acre cut for fodder, not threshed. The oats were raised on pasture land never ploughed but once, and planted with potatoes the last year and manured in hills, this year harrowed, and 200 bushels of leached ashes spread on. I have 40 tons of English hay, cut the present season; 16 tons of black grass hay, 15 tons of salt and fresh hay, 60 barrels of winter apples, 11 barrels of cider, 40 bushels of beets and carrots, some pears, peaches, grapes and plums. I keep 1 horse, 4 oxen, 9 cows; calves

sold 50 dollars; milk sold at the house 1500 gallons at 14 cents; and made some cheese in the hot weather. I have a son who takes the principal care of the farming. We hire two men seven months, at 17 and 18 dollars per month. We buy manure in Newburyport at \$1 75 and \$2 per load of half a cord or more; ashes 6 cents a bushel. I sell hay at \$41 per ton. Onions are sold at 50 cents a bushel. Omen ground we manure with about 12 loads to the acre; plough it in the fall; about 15th of April plough it again and sow when the ground is fit. I sow in rows 16 inches apart, three pounds of seed to the acre; two pounds are enough if we were sure all would be right; I think if we have plenty of manure it is best to plough it in; if we have not a plenty, make the best of it and put it in the hills; then we shall not miss unless a very dry season. To cultivate an acre of onions on my ground, would cost about 25 days labor.

Summary of the Above.

No. of acres, 110.	
Products.—Indian corn, on 5 acres, 200 bushels.	
Potatoes, 6 acres, 1500 bushels.	
Onions, 13-1 acre, 740 "	
Beets and carrots, 40 "	
Winter rye, one acre, 26 "	
Barley, 3 acres, 100 "	
Oats, 1 acre, 75 "	
English hay, 40 tons.	
Black grass, 16 "	
Salt and fresh hay, 15 "	
Winter apples, barrels 60	
Cider, 11	
Milk sold at the house at 14 cts. per gall., 1500 gallons.	
Calves sold, 50 dollars.	
I raise plenty of peas, beans, cabbages, turnips, squashes, &c.	

I should like to find some machine to dig potatoes with oxen or horses.

November 28, 1839.

Quick as Magic.—In the presence of seventy-eight persons in London, a parcel of rags were recently taken, made into paper, dried, and printed on in five minutes! When this celebrity becomes universal, letters will have to dodge paper mills, or their ragged vestments will be whipped off and exhibited under their noses in the shape of a hand-bill, advertising them as vagrants before they know it!—*Hibernian Farmer.*

The writer remembers the time when a pen of sheep were shown as candidates for a prize at a public exhibition in England, after which they were shorn, and the wool was scoured, carded, spun, dyed, made into cloth, cut and made into a coat, which was worn by one of the officers of the society at the public dinner-table on the same day!!—*Furmer's Cobia L.*

"In the preservation of seeds, grain and vegetables, infinitely more pains are taken in Europe than with us, to preserve the varieties distinct and unaltered. In the highlands of Scotland there are certain districts appropriated solely to garden seeds, and no two varieties that are in danger of becoming adulterated by being placed near each other, are allowed to be cultivated in the same district."

It is said fresh meat may be preserved free from taint for many months, by keeping it immersed in molasses.

NEW ENGLAND FARMER,
AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JUNE 3, 1840.

ENCOURAGEMENT TO AGRICULTURE IN MASSACHUSETTS.

It is often sincerely asked, what are the encouragements to agriculture in Massachusetts? Her climate is cold; her soil hard, and much of it sterile and unproductive; and labor expensive and difficult to be procured; and we have comparatively no mineral manures by which an exhausted soil may be rendered productive. We admit all these disadvantages; and yet in spite of them all we believe there are few situations where agriculture affords a more full compensation. We do not propose to go largely into this subject at this time; and we shall throw out only a few hints for others to work up at their leisure; and suggest such data as may afford the groundwork of sound inferences and conclusions.

We state with entire confidence, as we have stated on other occasions, and shall repeat it again and again, because we think it should not be forgotten, that there has not come under our observation in any part of the State, a single agricultural improvement intelligently and skilfully conducted, where the returns have not been most ample; and in many cases the products of the two first years succeeding the improvement, have more than repaid all the expenditure. The improvements to which we refer, have been effected by removing stones from land; by ditching and draining; by gravelling low meadows; and by high cultivation and manuring. Some of the most expensive improvements of this kind have cost, in removing stone, for example, one hundred and fifty dollars per acre; and the land which previous to the improvement was deemed of little or no value, now yields three tons of hay to the acre, and in a neighborhood where this hay always commands the highest price. Now estimating the hay at 15 dollars per ton, the crop would produce 45 dollars. Allow half of this sum for getting the hay and keeping the land in condition, and this will leave \$22.50 as the annual income of the land; and this is the lawful interest of \$75 dollars. What more certain or what better stock as an investment is to be found than this?

We lay it down as a sound, undeniable position, that there is not a single crop cultivated among us, if the cultivation be judicious and faithful, which does not return an ample profit. Crops which in defiance of all propriety are planted on lands not at all suited to their growth, which are only half tilled, imperfectly or improperly manured, choked with weeds or injured by wetness, certainly are not to be taken into the account. But those which are cultivated with sound judgment and fidelity, on a soil adapted to the nature of the crop, and thoroughly prepared, never fail, with a propitious season, to yield a fair profit. One of the most expensive crops cultivated among us is Indian corn. With good cultivation it certainly is not difficult to get fifty bushels to the acre. Valuing this at 75 cents per bushel, the return is \$37.50. Now if we must buy all our manure at an expensive rate for this crop, very likely it would bring us in debt. But the farm ought to produce its own manure. Not charging the manure, therefore, the cultivation and harvesting are not likely to exceed 20 or 25 dollars. But the balance which remains after these expenses are deducted is not the only profit accruing from the crop. The fodder from an acre of corn yielding 50 bushels, if well cured, is fully equal for almost any

stock, to a ton of the best hay; and the manure applied to the corn crop may be expected to yield its advantages to the land for at least three years after its application. No crop, if it be well cultivated, affords a better preparation for a crop of wheat. What we have said of corn applies to many other crops. If we take land yielding but a ton of hay to the acre, and should value this hay at ten dollars per ton, and allow half that sum for getting the hay and keeping the land in condition, there will remain five dollars as the annual income of this land. But in general such land would not in any part of the State, be valued at more than thirty dollars per acre; whereas at fifty dollars per acre, it would be equal to a return of ten per cent. upon its value.

There is another fact in the case, that in general, other circumstances being equal, the agricultural population of Massachusetts are in respect to their pecuniary condition, as well situated as any class in the community. There are indeed many and painful exceptions, where farmers involved in debt beyond the hope of extraction, find themselves burdened by heavy mortgages, and their estates gradually wasting away under the disastrous accumulation of unpaid interest. So, likewise, it may be said of every other class in the community. But such results are in general traceable to other causes than their farms; to speculation in wild lands, in multicaulis trees, in factory stock, or some other departure from their legitimate pursuits. In general such results are not referrible to the cultivation of their farms, but to the neglect of cultivation; and we may believe it may be said, with perfect truth, that there is not a well cultivated and well managed farm in the State, which does not yield a profitable return.

In this case we seldom do justice to the farm. We credit it with that only which we sell, without making any allowance for that which we get and use from it. Large families, even with moderate labor, are often sustained from a farm without any credit being given to the farm for their support. They have from it house rent, fuel, milk, cheese, butter, eggs, poultry, vegetables, fruit, bread, beef, pork, mutton, wool, and these in no measured quantities, and yet though beyond this the farm pays its taxes and the expense of its hired labor, these farmers will be incessantly complaining of the unprofitableness of agriculture.

We add in the last place, that there are innumerable instances scattered all over the Commonwealth, in its most favored and in some of its least favored localities of men who have acquired by honest industry, sobriety and frugality, by farming even in Massachusetts, not only a competence but an independence; have brought up large families well; given them the best advantages of education; and though beginning life perhaps in debt, and with nothing to depend on but their own hands, have kept themselves without embarrassment, have maintained their families with respectability, have exercised a generous and unstinted hospitality, and have enough to enable them to pass the evening of life without fear or want.

We leave these considerations to our readers, not disposed longer to tax their indulgence; but shall ask leave on some more convenient occasion to resume and enlarge upon the subject.

H. C.

BEEF SUGAR

Preparations are making in some parts of the country to go largely into the cultivation of beets for sugar. In the neighborhood of Baltimore one gentleman, it is said, has sixty and another eighty acres in beets for this purpose. A gentleman familiar with the cultivation of the cane and the manufacture of sugar in Louisiana, says

distinctly and emphatically from his own experiments, having made 600 lbs. of best sugar the last year, that he has no doubt that the cultivation of beets for this purpose in climates congenial to it, will yield a larger profit than the cane, taking into the account the value of the material remaining for the feed of stock, and actually more pounds of sugar to the acre. He thinks he has made very important improvements in the preparation of the beet and the extraction of the saccharine matter; and is in the process of erection of a large establishment in the vicinity of Baltimore.

H. C.

SILK.

The product of silk is spiritedly engaged in in many parts of the country; and this year will, in respect to this matter, be prolific in most important results. Vast numbers of the multicaulis have, in some situations been thrown away from the impossibility of finding persons who were willing to accept them as a gift; but on the other hand, many individuals who had large plantations set out with no view to the production of silk, but solely with a view to speculation, from being unable to sell their trees, have turned their attention to feeding worms. We have no doubt, where cheap labor or that which would otherwise be unproductive, can be obtained, the production of silk will yield not only a fair but an ample profit, and make a valuable branch of husbandry even in New England. Perhaps in the end, after the tender trees become acclimated, or the mode of arranging them is better understood, our State will prove more favorable than other parts of the country, as temperate or rather cold latitudes are found to produce a better silk, and to be more congenial to the health of the worms than hot climates. Extensive cocooneries are already in operation in New Jersey, Pennsylvania, Maryland, District of Columbia, and Virginia, besides several in different parts of Massachusetts. May the best success attend them.

H. C.

Massachusetts Horticultural Society.

EXHIBITION OF FLOWERS.

Saturday, May 30th, 1840.

Notice Flowers, from Miss Dix, Dr Harris, and Mr Parker.

Bouquets, from Messrs Jno. Hovey, R. Howe, Miss Sumner, A. Bowditch, W. Kenrick, and S. Walker. Viola grandiflora, from A. Bowditch, and S. Walker. Erica, variegata: in fine order, from Mr Eustis, Oak Street, Boston.

From William Kenrick, Iris, varieties large Blue Versicolor, Graminea, or Grass-leaved, tall, blue, and beautiful; Swertia, new and beautiful; Florentina, White—Paeonias, Montan, P. Rubra, P. Carnea, P. Rosa, and some other kinds. Laburnum or Golden Chain, Yellow Flowering Horse Chestnut. Harrison's Double Yellow Roses, Narcissus, Blue Traubscantia, London Pride, Hemerocallis flava, or Yellow Day Lily, Purple Beech, Vicia cracca, which bloomed this year in a splendid mass, and is perfectly hardy in high and elevated situations.

For the Committee.

S. WALKER, *Chairman.*

Leached ashes are worth at least six cents per bushel, to incorporate into a gravelly soil; and unleached are worth four times as much as leached. Care should be taken to mix unleached ashes with the soil.—*Albany Cult*

The communication of W. B. shall have a place in our next.

BRIGHTON MARKET.—MONDAY, June 1, 1840

Reported for the New England Farmer.

At Market 320 Beef Cattle, (including 35 unsold last week) 20 pairs Working Oxen, 10 Cows and Calves, 140 Sheep and 450 Swine

Prices.—Beef Cattle—We reduce our quotations to correspond with sales. We quote a few extra, \$7 25. First quality, \$6 75 a \$7 00. Second quality, \$6 25 a \$6 70. Third quality, \$5 75 a \$6 35.

Working Oxen—A few sales at \$75, \$80, \$92, \$110, and \$140.

Cows and Calves—\$20, \$21, \$25, \$28, \$32, and \$40.

Sheep—Lots at \$3 75, \$4 00, and \$4 12

Swine—“Dull.” Lots to peddle, were sold at 1-1-4 a 1-2 for sows, and 5-1-4 a 5-1-2 for barrows. At retail from 5 to 7-1-2.

100 Beef Cattle unsold.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded northerly exposure, week ending May 31.

May, 1840.	7 A.M.	12 M.	5 P.M.	Wind.

Tuesday,	26	50	78	67 S.
Wednesday,	27	58	84	76 W.
Thursday,	28	65	90	78 W.
Friday,	29	65	77	63 S. E.
Saturday,	30	53	73	67 S. E.
Sunday,	31	60	73	67 S. E.

FOR SALE OR EXCHANGE.

A valuable Farm in Harvard, County of Worcester, the well known Brownfield Place; an excellent dairy farm, well wooded, the house spacious, fitted for two distinct families, or a private or high school. Bordering a part of a farm is a beautiful sheet of water, containing two islands belonging to the estate. Inquire of the subscriber at South Natick. June 3. I. H. T. BLANCHARD.

WALKER'S SPLENDID TULIPS

Are now open for exhibition, at the Public Garden, four of Beacon Street, and will continue for several days.

Since the last exhibition, great additions and improvements have been made. The bed, the present season, will contain up to 5000 Bulbs, all of them rare, and the Flowers very beautiful; among them will be found several varieties that obtained the Queen of England's Plate Prize, at Hampton, in May, 1838.

A suitable House, 120 feet long, by 18 feet wide, to comport with the dimensions of the Bed (which is double the usual size) has been erected by the Trustees of the Garden, and all the arrangements have been made with reference to the gratification of the Public.

Admission to the Tulips, free, and the Conservatory, 12 1/2 cents.

Open every day, (Sundays excepted) from sunrise until sunset. May 16.

CARNATION SEED.

The Subscribers have received from Rotterdam, a small quantity of extra fine Carnation Seed, saved from one hundred choice varieties, which they offer at 25 cents per pound. We have tried it, and find that it vegetates freely. It cost is 30 quills per ounce, and from the press attention made, do doubt will give satisfaction to those who may be disposed to try it. We have also very fine carnation seed at 12 1/2 cents per paper. The seed may be sown with good success any time in May or June. JOSEPH BRECK & CO. May 20.

THE BOY'S COUNTRY BOOK

Of amusements, pleasures and pursuits, illustrated with 22 original designs. By WILLIAM HOWITT. One of the best books for boys ever published. For sale by JOSEPH BRECK & CO. April 20.

FOR SALE.

For sale a fine better Calf, from one of the best cows in the county, and by the celebrated Ayrshire bull imported by Mr Cushing. Inquire at this office, or at Wmshup's establishment at Brighton. May 20.

LIME FOR MANURE.

150 Casks Lime, partially slacked, will be sold low, by his subscribers, at No 30 Sea Street, Boston. May 20. SOLOMON PIPER & CO.

SCYTHES, RAKES, &c
The subscribers offer for sale a very extensive and complete assortment of Scythes, Rakes, &c, consisting in part of 300 dozen Phillips, Messer and Colly's scythes
50 " Metcalf's do do
25 " Tait's cast steel do do
50 " English do do
10 " do do do
10 " do do do
100 " Hall's Bikes, superior
100 " Wilder & Edly's do do
200 " Common do do
100 " Clapp's patent Scythes
50 " Baker's do do
100 " Common do do
200 " Ames's superior Hoes
200 " Common do do
1000 " Scythe Stones
100 " Gram Cradles superior.

They would respectfully call the attention of Dealers and Agriculturists to the above assortment, which consists of many of the best kinds now in use, and which they are prepared to sell at the very lowest prices.

JOSEPH BRECK & CO.

New England Agricultural Warehouse and Seed Store, 51 & 52 North Market Street, May 20.

FARM FOR SALE.

The highly cultivated Farm of the late Captain A. Delano, situated in North Charlestown, N. H. four miles from the flourishing village of Clamont, containing 160 acres of first rate arable and wood land, with a well finished two story dwelling house with all necessary out buildings, including water at house and barns, two good barns, with shed 50 by 20 feet, and all necessary buildings for a well stocked farm; together with a good assortment of young fruit trees, among which is a fine variety of pear and apple in a flourishing condition, with two good gardens. Terms liberal. Apply to H. F. DELANO, on the premises, or ISAAC HUBBARD, Esq. Clamont. North Charlestown, April 3, 1840.

MULBERRY TREES, SEEDS AND EGGS.

WILLIAM PRINCE & SON, Flushing, offer for sale very fine large trees of Mulberries, of the variety of Elata, Albino and Broussa Mulberries, at low prices and long credits. Also, Albino, Elata, and Broussa Seeds at 83 per ounce. Peanut and all other valuable varieties of Eggs at 83 to 85 per ounce. The seeds and eggs can be sent by mail. 500 pounds Mangel Wurtzel, and 700 pounds Sugar Beet, at reduced prices, 100 bushels genuine Rohan potatoes. 1000 pound Lucerne Seed. Orders per mail will meet with prompt attention. May 13.

FARMING AND GARDEN TOOLS.

For sale at the New England Agricultural Warehouse and Seed Store, No 51 & 52 North Market Street
100 dozen Cast Steel Hoes.
200 " Crooked Neck Hoes.
200 " Common do.
100 " Prong do.
100 " Garden do superior.
100 " Ames' and other Shovels.
50 " Spades.
100 " Manure Forks.
200 " Hay do
300 pair Trace Chains.
600 " Oz do
200 Halter do
300 Chains for tying up Cattle.
Together with a most complete assortment of Farming and Garden Tools of every description. JOSEPH BRECK & CO. March 11.

GARDENERS KNIVES.

JOSEPH BRECK & CO have this season imported and now offer for sale a few very superior Garden Knives, for pruning, &c, manufactured expressly for Gardeners, and warranted superior to any article of the kind before imported.

Also—a large assortment of Building Knives, Grape Scissors, &c &c. April 22

PURE BLOODED STOCK.

For sale, three young Bulls, 7 to 9 months old, from improved shorn born Durham, Alderney, and North Devon Stock. Inquire at this office. April 29.

HORTICULTURAL TOOL CHESTS.

Containing a complete set of Garden tools of superior finish and style, recently received from Liverpool and for sale at the New England Agricultural Warehouse and Seed Store. May 6. JOSEPH BRECK & CO.

FINE DOUBLE DAHlias.

For sale by JOSEPH BRECK & CO, No. 52 North Market street, at reduced prices, a splendid collection of Double Dahlias. May 20.

WHOLESALE PRICES CURRENT.

CORRECTED WITH GREAT CARE, WEEKLY.

(Continued from page 398.)

Maysville, I believe, is the oldest town in Kentucky; it is regularly laid out into squares; the buildings are chiefly of brick, and the town presents a compact, city-like appearance; but the streets are abominably filthy. It is said to contain 3000 inhabitants. Exactly opposite Maysville is Abercree, apparently a pretty village. The country around is hilly, and the soil does not look as good as the average in this section of the country. Maysville is 60 miles above Cincinnati. Ten miles below we passed Dover, a pretty village in Ohio; and six miles further, Higginsport, Augusta, a very pretty town in Kentucky, contains a considerable population, and has a handsome courthouse and college, which were pointed out to me by a traveling friend who had spent some time there. Ten miles further brought us to Moscow, Ohio, where we stopped to wood: this is a small but pleasant village. The soil here is Moscow and between that place and Cincinnati, appears to be of the best quality, and the forests are really magnificent. The first view of Cincinnati as seen from the river above, is not very prepossessing, but when abreast of the city it appears very well. We arrived at 6 o'clock, just 52 hours from Pittsburg, distant by the river about 500 miles.

Cincinnati, like most of the large towns in the west, is laid out in squares; the streets crossing each other at right angles; the buildings are chiefly brick, in plain style; the public buildings are few, the most remarkable of which are the Episcopal and Catholic churches, and the Bazaar, built by Mrs Trollope, and now owned by the Mechanics' Institute. The latter building is not large, but is remarkable for its oddity, being in oriental style. Many of the streets are ornamented with shade trees, and the city appears neat and handsome. Order and quietness pervade the whole, and, compared with eastern cities, the business is not very great for the size of the place: in this respect it is not what it is "cracked up to be." There are about a dozen churches in the city, and the population is said to be 30,000. The market is well supplied until 12 o'clock, when it is closed. The last of May there were plenty of strawberries, cherries, and green peas in market. The general customs of the place are more like New York than any other place with which I am acquainted.

By climbing a high hill on the north of the town I obtained a fine view of Cincinnati, Covington, Newport and the river. The two latter towns are exactly opposite Cincinnati, and are separated by the Licking river, which joins the Ohio here. These places are surrounded by high hills, which hide them entirely from any distant view. These hills at present are very little cultivated, being chiefly occupied as pasture; but when rich citizens shall improve the many fine situations about the town, the environs of Cincinnati will be very beautiful.

I left Cincinnati by the Miami canal at 5 o'clock in the afternoon of a blustering day, so cold that I was obliged to wrap myself in my cloak and was soon out of sight of the city. This canal is circuitous, winding around hills and valleys, through a district of excellent land, producing in the average 50 bushels of corn to the acre, and other crops in proportion. Farms are valued at 50 to 100 dollars per acre.

Early the next morning I arrived at Hamilton, the shire town of Butler county, situated on the

Miami river, distant from Cincinnati by the stage road 26 miles. This is a smart town of considerable business. The public square is enclosed with a handsome iron fence and contains a handsome court-house, jail and county offices.

In the afternoon I took a walk into the country. In the vicinity there are several extensive flour mills. The farmers live easy; their soil is very rich, easily tilled, producing abundant crops, of which corn is the principal. They keep great numbers of hogs, but few cattle, pork being the article upon which they depend most for an income. In the opinion of experienced farmers the land has been injured by cropping too much with corn and keeping too few cattle. The hogs run at large, and consequently return but little to the cultivated land, which will ultimately become exhausted, rich as it is, unless a change is adopted in the management of the farms.

I left Richmond in the stage at 8 in the morning of the next day after my arrival; crossing the bridge into Rossville, we came upon the turnpike road, and, passing through Snaverville and Camden, at 11 o'clock we came to Eaton, the seat of Preble county, 26 miles from Hamilton. This is a small town, but being upon the great western thoroughfare of land travel, it enjoys considerable business. On the arrival of the eastern stage in the afternoon I left Eaton for Richmond, distant 16 miles, but owing to the bad state of the road, we did not arrive there until 7 in the evening. Richmond is situated on the left bank of the Whitewater river, in Wayne county, Indiana, 4 miles from the Ohio line, in the midst of a fine agricultural district, and the most thriving in the State. A large part of the population are Quakers, who have a very large meeting-house in a fine grove to the northeast of the town, and their influence gives a healthy tone to society. The town is substantially built, and is said to contain 3500 inhabitants. The national road makes the principal street from east to west, which is crossed at right angles by wide streets, ornamented with trees. The banks of the river are about 40 feet high, and the excavation for the national road exposes a very extensive deposit of shells and other organic remains in rare perfection, cemented by lime, forming a bluish conglomerate, easily broken into fragments. In the neighborhood of the town there are large tracts yet of the primitive forest, containing sugar maple, beech, ash, oak, black walnut, hickory, bass, tulip tree, and some minor plants, among which is the pawpaw.—The trees are of the largest growth, and without limbs for 30 or 40 feet from the ground, and far enough apart to admit of riding: there is no underbrush, and were it not for the fallen trees, a carriage might pass in any direction. The soil is deep and rich, but rather too moist generally; the subsoil is stiff clay; the water is bad. I remained several days, and on the whole was more pleased with Richmond than any place that I had yet seen. Returning from church on Sunday, I met a friend in the street who had just arrived in town, and with whom I afterwards travelled to Illinois.

(To be continued.)

Mind your own business.—Every man has in his own life follies enough—in his own mind troubles enough—in the performance of his duties deficiencies enough, without being curious after the affairs of others. If every one attended only to their own affairs, this world would become a much more pleasant place to reside in than it now is.

SILK WORMS EGGS.

Just received, a few ounces of Silk Worms Eggs, from Smyrna, said to be of a superior variety. Price \$3 per ounce, clean seed. JOSEPH BRECK & CO. April 1.

SIX SILK WORMS EGGS.

The Eggs of the celebrated *Sauz Silk Worm*, now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The *Sauz Silk Worm* was introduced to France from China by Louis XVI. in 1784, and has been proved by 51 Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin who is the only agent for their sale in France.

Each sheet contains an ounce and is signed "Camille Beauvais." Price 50c.

Apply to J. SEPH BRECK & CO. Newton. March 25 1841

BROUSSA MULBERRY SEED.

We have recently received 50 lbs. fresh Broussa Mulberry Seed, which we offer by the ounce or bush. March 11 JOSEPH BRECK & CO.

BONE MANURE.

The subscriber informs his friends and the public, that after five years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

Orders for Bone Manure or Oyster Shell Lime, left at the Bone Mill, near Trenton road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention. March 4, 1840. NAHUM WARD.

BOX FOR EDGING.

JOSEPH BRECK & CO. have for sale 500 yards of Box for edgings, in prime order; price 3 1/2 cents per yard; every yard will make two when reset.

GARDEN MATS.

For sale at the New England Farmer, 100 dozen Garden Mats, of extra quality, for covering hot beds, &c. Feb. 12. JOSEPH BRECK & CO.

ROHAN POTATOES.

For sale at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, at 84 per barre, \$2 per barrel. October 16. JOSEPH BRECK & CO.

WEEK'S TREATISE ON BEES

For sale by JOSEPH BRECK & CO. April 15.

NEW AMERICAN GARDENER.

FOURTEENTH EDITION.

The New American Gardener, containing practical directions on the culture of Fruits and Vegetables, including Landscape and Ornamental Gardening, Grape Vines, Silk, Strawberry &c. by Thomas G. Fessenden, late editor of the New England Farmer. For sale by JOSEPH BRECK & CO. 51 and 52 North Market Street. May 13.

BONE MANURE.

A good supply of ground bones constantly on hand, and for sale at William Chase's mill, one and a half miles north-west of Providence bridge.

A sample may be seen at Remington and Whitman's store, No. 32 Market St. Providence, R. I.

Also, Bone Mills on a new and improved construction, for sale at the above place. April 8.

GOLD FISHES AND CANARY BIRDS.

For sale by JOSEPH BRECK & CO. 52 North Market Street. April 29.

FIR TREES.

Now is the best time for transplanting Fir Trees. Orders for any variety or size will be promptly attended to. May 6. JOSEPH BRECK & CO.

THE NEW ENGLAND FARMER

Is published every Wednesday Evening, at 53 per annum payable at the end of the year—but those who pay with in sixty days from the time of subscribing are entitled to a reduction of 5 cents.

WANDERINGS IN THE WEST IN 1839.

No. III.

(Continued from page 404.)

Having purchased a horse and wagon I left Richmond in company with my friend, and following the Cumberland road, we crossed the river on a handsome stone bridge, and passed through Centreville, Germantown, Cambridge city, (which is the county seat,) and Dublin, all of them small towns, but containing many good buildings and growing rapidly.

After passing Dublin the land is more flat and swampy, and there are fewer clearings, and the road for the most part is extremely bad; a smart shower in the afternoon caused us to seek shelter at a public house.

The weather being fine the next morning we started early, and passing Lewisville, Ogden, and Raysville, we came to Greenfield, the seat of Hancock county, 20 miles from Indianapolis.

The road we travelled over today was execrable. At all the creeks there are steep precipitous banks of hard clay, which are really dangerous. I was twice thrown out of my wagon at these pitches, and many places were so bad that I dared not ride at all. Many of the streams are deep and muddy, and most of them are entirely without bridges. The country is very flat and low, so that the water cannot pass off, but stands in pools, sometimes for miles on the sides of the road, until it is evaporated. The water of the wells has a strong smell of sulphur, and glasses soon become corroded; our horses refused to drink it unless very thirsty.

Greenfield is a small town of about 30 houses, a neat court house, two taverns, and several stores.

We left early in the morning, and found the road similar to that we travelled over yesterday, until we came within 2 or 3 miles of Indianapolis, when we came to a district a little more rolling and dry. We reached the metropolis early in the afternoon and stopped over night.

Indianapolis covers a large area, has a population of about 4000, and contains some good buildings. The capitol is a good looking edifice, in the Grecian style, built of brick and stuccoed in imitation of marble. There are two other buildings going up in the same style—one for the Parrot State Bank, the other for the Branch.

The merchants have a custom which I never noticed elsewhere, of hanging a festoon of red cloth, generally flannel, over their doors to catch the eyes of a passenger at a distance, and these are the first objects that attract the notice of a stranger coming into town. The business of the place is small and particularly dull at this time, owing to the scarcity of money and the suspension of the public works. Indianapolis is the focal centre of the splendid internal improvements of the State; and when they are completed according to the original plan, it must become an important city. There is but little attention paid to education, and the influx of adventurers and foreigners attracted hither by the public works in the vicinity, has exerted a deleterious

influence upon the morals of the people, gambling and dissipation being too common, and petty theft scarcely rebuked.

About 10 the next morning we left town, crossing a noble bridge built at the expense of the U. States, being in the route of the national road, and travelled 16 1-2 miles to Little's, where we arrived just in time to escape a tremendous tempest, which lasted till dark.

The next morning we started at 7 o'clock, found the road very muddy; the land not quite as flat as it is east of the capital, but yet too low and level to be healthy; there are short hills pretty steep, and being composed of hard clay, the rain had made them very slippery, and the travelling was very tedious. We passed several little straggling villages which are dignified with the name of towns, for in this part of the country a petty tavern and grocery makes a town, and if there be a blacksmith's shop and two or three log cabins beside, it is "a right smart town." We stopped for the night two miles west of Belmont, a town of the latter class.

According to my usual custom, I made particular inquiries about the country, and I learned that it is generally unhealthy in the latter part of summer and autumn, when bilious fevers and ague prevail. There are some public schools in which are taught orthography, reading, writing and arithmetic, and the people seem to have no idea that any other branches are necessary except for doctors and lawyers. The farmers pay but little attention to their cattle; they have good horses and abundance of hogs. Corn and oats are their principal crops; they raise, however, some wheat, flax and a few potatoes; gardens are very rare; the soil is well adapted for trees, and they have some good orchards. Their living is plain and uniform—warm cakes, bacon and coffee, with eggs occasionally.

The next morning we moved on through Putnamville and forded a considerable river, but found the roads so muddy that we concluded to stop at Manhattan until the next day. Near Putnamville there is a quarry of the best building stone to be found in the western country. It is a compact limestone, and there are a good many men employed there.

Leaving Manhattan we rode until noon, when we were overtaken by a heavy rain and took refuge in the cabin of a settler from "York State," whom we found very communicative and tolerably intelligent. This part of the State has been recently settled and is very little improved. The land is mostly entered but is still cheap. There are at present no public schools, and a few years since the people had to go to Vincennes to mill, 40 miles, in boats. The rain having slackened we started, but had not gone far before the windows of heaven were again opened upon us, and we had to ride in the rain 14 miles to Cunningham's, where we found a good stable for our horses, a rare thing in this country, and excellent accommodations for ourselves, which our drenched situation made doubly agreeable.

Resuming our journey in the morning, we found that the heavy rains yesterday had made the road

very bad until we got to Harrison prairie. This prairie is 3 miles wide and about 12 miles long, and is nearly all fenced and under cultivation, and being what is called sand prairie, the water was nearly all absorbed.

Terre Haute is delightfully situated on the western edge of the prairie, and on the east bank of the Wabash, and is quite a handsome town. Its high and dry situation would lead one to suppose that it is healthy; but like all other river towns in the west, it is far otherwise. However it has a good share of business and is fast gaining in importance.

Having mentioned the Cumberland or national road, as it is called, upon which so much of the public treasure has been lavished during more than twenty years past, it will be proper to say a few words about its present condition and the public sentiment with regard to it. This road commences in Virginia, and is laid out in nearly a straight line across Ohio and Indiana, in a direction a little south of west, and will perhaps be continued to the Mississippi river. The road is macadamised and finished in the most durable manner as far as Columbus in Ohio. About four miles at Richmond, Ind., a short piece at Centreville, about six miles at Indianapolis, and three miles at Terre Haute, together with a few bridges are completed in the same substantial manner; the remainder of the way the road has been graded, that is, the road bed has been formed with earth, some of the hills have been excavated, and valleys embanked, and in that situation has been open to the public travel. In wet weather holes will be made in which the water settles and the continual passing soon wears into cradle holes and gulleys which frequently become impassable, then a few logs are thrown in, often by travellers themselves, just sufficient to enable them to get over, though not without peril. In this way the road has been cut up, and the labor that has been done nearly lost; yet this is the great thoroughfare for western travel, and bad as it is, perhaps there is none better in Indiana. The people say that it is a national concern and that the federal government is bound to complete it, and they will not meddle with it. In the mean time it furnishes a fertile subject for party politicians to quarrel about, and a stump speech would be deemed incomplete without some flaming passages respecting the national road.

We stopped only one day at Terre Haute and left in the afternoon of the next, and hearing that the road was very bad on the other side, we went 7 miles up the river and crossed at Durkee's ferry. The river here is 240 yards wide. Our road was through timber for five miles, when learning that there were no taverns nor any houses for some distance ahead, we stopped at a farm house where we were well accommodated.

The next morning we resumed our journey over a bad road, through timber and barrens, skirting the grand prairie, and at 11 o'clock we reached Paris, the seat of Edgar county, Illinois. This is a pretty town, built in the form of a hollow square; the court house and other county buildings occupying

the centre. Leaving Paris we entered upon the grand prairie. To the north as far as the eye can reach, we could see nothing but an ocean of grass; to the south and west timber could be seen, but at a great distance. The nearest house upon the road is ten miles from town. Some two or three miles north of the road Mr Bradshaw, an English gentleman, has an estate of 3000 acres, most of it fenced. His house is on a little eminence in the edge of a small grove, and commands a view of the whole country from ten to fifteen miles round.

(Continued on page 412.)

For the N. E. Farmer

CIDER AND APPLES.

MR COLMAN—I promised in my last letter to say something about cider; and I hope you will not consider this choice of subject, at this particular time, as having any special bearing on "hard cider," for my object is, to make good cider for both political parties.

The common wines of France are not much stronger or better than our common cider, and not so good as the best. If those wines were treated no better than our cider is, in the making and keeping, they would be no better than hard cider, and not fit to be drank in "log cabins."

Mr Editor, it is hard to get rid of old habits; and the very word cider is now bewildering my thoughts with politics, although I detest professed politicians. Permit me, therefore, a short digression, and I will then drive these thoughts from my mind, and go back to my real cider barrel. When I saw a log-barn in New York, with fire and drink within, there flashed into my mind a Latin verse, from what author I do not now remember, but so applicable, as a motto for the log cabin, that I would have offered it to the *hulites*, if I had known them. The verse was made on the occasion of some nuptial festivities, and very ancient. This shows that the new ensignia is very classical, let those who ridicule it say what they may about it:—

"Inde casas postquam, ac pelles, ignemque et potus paravit."

When huts and skins and fire and drink they had prepared.

In France, the grapes from which the wine is made, are carried immediately from the vineyard to the press, and are not allowed to remain for weeks in heaps, and go through the several degrees of fermentation to the putrid, like our apple heaps; although in some places, where a sweet wine is wanted, the grapes are spread to the sun in dry places, to permit them to evaporate a portion of their more aqueous parts before they are pressed. This is a cheap mode of concentration without boiling, as we boil cider sometimes.

As soon as the liquor is expressed, it is put to ferment; and as soon as that is completed, it is put into light, clean, sulphured casks, which are kept constantly full, bunged hand-tight and air-tight, with clean linen bung cloths: hand tight, for the convenience of filling up every day, to keep the liquor from the air and prevent the acetous fermentation.

After a certain time, (differing with different wines, climate and other circumstances, which experience indicate,) the wine is drawn off the lees, and still kept in casks always full. This exclusion from the air is the great secret; and the filling up should never be with bad liquor; it would be better to do it with water than with cider on the turn.

The exclusion of the air and the drawing from the lees, are sufficiently important to merit particular consideration. And to show that the ancient epicureans understood this matter well, we have but to examine the shape and seeming whimsicality of the vessels in which they kept their precious wines, called *amphori*, and now found in the cellars of Herculaneum and Pompeii. These amphori are made like the olive jars, with small mouths and pointed at the lower end, so that they cannot stand. The small opening at the top is to facilitate the corking and to expose the smallest surface possible to the air during that operation. They sometimes dropped in a little oil before corking, but this would be less efficacious with our cider barrels, which soon present a large surface of uncovered liquor. But Yankee ingenuity will remedy this evil one of these days, when they reflect on the reason of the thing. Now the tapered form of the lower part of the Roman amphori is to confine the remaining lees to as small a compass as possible; for these lees soon become tartarous, and finally a concrete tartar, and injure the liquor in the same ratio as their two surfaces correspond.

The manufacturers of our common junk bottles are guided by the same philosophy; although some people think the indenture at the bottom is to diminish the contents which would be against their interests, as some of them have of late discovered, who make bottles without that necessary indenture. Perhaps they were ignorant of its true use. The narrow space between this indenture and the sides of the bottle, confines the sediment of the liquor to the smallest surface, and answers the purpose of the Roman amphori. Yet we hear often of the advantage of leaving wines on their lees. Now if the lees be of very good old Madeira, and the wine put upon them be ordinary, it is not improbable that it will impart some of the Madeira flavor; but pure tartar or concrete lees of any wine can never improve liquor. All liquor should be kept cool and in dark places, and transvased as little as possible.

Cider or any other liquor may be fined by a very simple and quick process, by filtering it upward through sand. For this purpose, set a cask: endwise, fix to it a false bottom, a few inches from the real bottom; perforate the false bottom with holes; cover this bottom with a clean piece of cotton cloth; then on that spread a layer of fine clean sand, about six inches thick; over that spread another piece of cotton, and on that spread a layer of sand as thick as the depth of the cask will admit, so as to leave it a few inches below the top. Before this filter is so made up, a tube of wood or metal must be placed in the cask, going through the false bottom and rising above the open end of the cask. Through this tube the liquor is poured with a funnel, and forces its way upwards, leaving all impurities below, and flows out through a pipe or a notch at the top. If the sand should be compact and wet before the liquor is poured in. If it should be desired to filter cider on the acetous turn, or when it is becoming sour, it may be improved and almost restored, by adding to the filter immediately above the first layer, an extra layer of pounded charcoal and flour of sulphur—nine parts charcoal and one part sulphur. Then if the liquor prove dead or vapid, it may be enlivened and made a pleasant, brisk summer drink, by putting into each cask a small quantity of good yeast and rye meal, shaking and bunging well the casks.

I am informed that apples are sometimes so abundant in the Connecticut valley, that they are left to

rot on the trees. It seems to me that this should never happen. In such years of abundance, it would be well to pick the best of them and make cider that would be much better than usual, and keep longer. Perhaps something may be done with them in imitation of the treatment of grapes when sweet wine is wanted. A portable chopping trough might be carried from tree to tree, to chop the apples and leave them spread to evaporate for a few days; thus, there would be less liquor but richer in saccharine matter. The liquor then might be expressed for drink, or to be boiled down to molasses. Or, finally, the apples thus cheaply dried, would make good food for hogs and cattle—very nutritive and fattening.

I drink no liquor but water; and I had some scruples about writing this cider story; for I believe that water, and not much of that, is very conducive to a complete digestion of food; and consequently healthful. Water is, in the hands of nature, the great instrument of composition and decomposition of all animal and vegetable matter. However, apple trees we shall have, apples we shall eat, and cider we shall drink; let us therefore use them all to the most advantage. The trees themselves, may I believe, be made to act a more important part in rural economy than heretofore. They now occupy large tracts of good arable land; often the best part of a farm, with the finest southern exposition; whereas they might be made the protecting bulwarks of minor vegetation, keeping off the northern enemy which sometimes lays prostrate acres of thrifty corn. They would also attract moisture from regions which the more humble vegetables cannot reach.

In making borders of apple trees to the northward, I would recommend, however, not to make them single, but of more rows than one, according to circumstances, that the protection may be more effectual, and that they may protect each other also.

Frederick Tudor, Esq. has succeeded in raising a large number of fruit and ornamental trees, in one of the most exposed situations on the coast of America—on the northeast side of Nahant, a high promontory projecting out into the open sea, simply by the aid of a high, open, slat fence.

Your friend and humble servant,

WILLIAM FOSTER.

To Preserve Fence Posts, &c.—It is often the case where lime is used for plastering and other purposes, the siftings and refuse are thrown away as useless. But it is better economy to put it around fence and gate posts, as it will greatly preserve them from decay. Leached ashes are very good for the same purpose. If slacked lime or leached ashes were sprinkled over the wooden pavements in our cities when first put down, it would render them much more durable than when sand or gravel alone is used.—*Genesee Fir.*

Caking of the Bag or Udder in Cows.—In newly calved cows, the udder sometimes hardens or cakes as it is called, and a remedy should be applied without delay. One of my cows in this condition, was lately treated with *soft soap*, externally applied in the evening, and the next morning she was well. I have heard no complaint of her since.—*Corr. of Genesee Fir.*

Water in which potatoes have been boiled should never be given to animals, as it is poisonous.

From the Boston Courier.

CANKER WORM.

To the Editor of the Courier:

I was grieved, on passing through Brighton, North Natick, and many other towns in this neighborhood, to observe the desolating effects of the spread of the canker-worm over some of our best orchards. The appearance is most unpleasant to the eye, as well as ruinous ultimately to the tree—as it occasions a second production of the foliage, and this, if it continues for a succession of years, is most destructive of vegetable life in all trees.

Many of the modes of prevention, too, are as ruinous as the worm itself. The application of tar to the bark I have had occasion to rue! Oil is bad in any mixture, and in fact, whatever has been resorted to, seems, from the expense, or some other cause founded on want of attention or experience, discouraging.

The object wished for by many is, that our farmers would try how the worm can be circumscribed in its ravages or destroyed on the tree. Many observations have been suggested by intelligent farmers on this head:—First, when the dew is on the tree, to throw ashes or lime amongst the leaves.

This, if effectual, would be the most thorough mode—as it would have the effect to close the career or inroad of these desolating visitants.

But it will be recollected that this experiment must be immediately made, as the worm is about descending into the earth to lie by for another year.

The writer, by an application of this sort, put an end to the ravages, some years since, of a species of slug-worm, and entirely destroyed them. The exterior covering, however, of the canker-worm, is not so favorable for success in this experiment.

If too late for this trial, for I have observed that some of the worms have finished their work and began to descend, the next object is their destruction or discouragement in the earth.

That they can be lessened or destroyed by the application of lime-ashes, or some caustic matter, seems to be a prevailing opinion with many ingenious and observing agriculturists, whose communications have been before the community through the publications made by the Trustees of the Massachusetts Agricultural Society.

That ashes and lime have been placed closely round the body of the tree, and with good effect, seems unquestionable.

This, too, is obnoxious to the borer; and that excellent observer, Mr Lowell, made use of a lime mortar, in which he encased the whole body of the tree near the ground, and prevented the entry of this pest. It is no small recommendation to the within suggestions to say that it is believed they coincided with his opinions.

The desire of the writer is, to invite a course of experiment through the whole progress and transmigrations of this destroyer during the year.

To do this a beginning must be at once made—and to this the co-operation of those who are thus severely annoyed, is invited forthwith.

I am yours,

J. W.

Dorchester, June 5th, 1840.

From the New Genesee Farmer.

To prevent the taste of turnips in butter.—One of your correspondents wants to know how to prevent the taste of turnips in the butter from cows fed on these roots, and having had some experience in the matter, I will give you an answer to the inquiry.

In some of the best districts in England, the taste of the cream and butter is affected by the manure used on the pastures, and the following means are adopted to prevent it. The first method is almost universally practiced on the milk and cream brought into the London market. It is this: Dissolve an ounce of nitre (saltpetre) in a pint of pure water, and put a quarter of the pint into every fifteen gallons of milk as brought from the cows. This will effectually prevent any bad flavor, and cause the milk and cream to keep sweet a longer time. The quantity of nitre is so very small, that it does not at all affect the wholesomeness of the milk.

2d Method—Let the cream get well sour; and before churning, take out a quarter of a pint of the cream and put it into a well scalded pot or jar, into which gather the next cream, and stir it well; do the same with each successive gathering, until enough is saved and well soured, ready for a second churning; then take out a small quantity and commence anew as before.

The cream being sour before churning, is no detriment to it, and this method will prevent any bad taste in the butter. Yours, W. R.

For the New England Farmer.

SCIENCE FOR FARMERS.

"JURISPRUDENCE—the science of law." And what have farmers to do with this? There is certainly a very peaceful and quiet profession—one that is most particularly calculated to excite and promote kindly and exalted feelings towards our fellow men, and indeed all things, else the injunction "dress the earth and keep it," had never been given by a kind and merciful father to man, who was created to be a happy and consistent being. But the Creator's magic which was so strongly impressed on the spiritual visage of him who was destined to fill a sphere "but little lower than the angels," has become strangely effaced; and instead of being a messenger of mercy and kindness to his fellows, man, in too many sad instances, is the very genius of wretchedness and ruin, and his perversion is so great, that unless restrictions are put upon his propensities, the earth, set moving in its sphere as a place where he might be happy, would become a perfect Pandemonium.

To the existence of such an undesigned state of things then, we must acknowledge our indebtedness for the necessity of lawgivers, magistrates and laws. The preservation of life, protection of property—indeed all the rights which men hold dear require their existence. But the fact that they do and must exist does not involve the supposition that men cannot be honest, industrious, and possess every other virtue, for which many have been highly distinguished without their restraints. There are those, we hope, in every community—we know there are in some—who would maintain the utmost integrity of character if there were no laws but those of conscience and heaven to direct them. There are others upon whom law imposes no restraint except such as arises from fear of punishment; and again those who choose to experience their utility and effect by practical illustration. For the former class laws were not designed, except as a protection: for the two latter they present a three fold influence—protection, restraint and punishment.

All laws then, are designed for the general good. They suppose every individual of a State or nation to be that State or nation, and in this way their bearing upon the whole is brought about in such a way that the effect must be alike essential to all. Hence they can give exclusive privileges to none, nor can they in any way detract from one individual's right of freedom or conscience, unless the good of the whole, himself included, require it. Thus the safety of the community requires that the thief should be dislodged from the community, and his rights of social intercourse disfranchised, and his own safety and well being requires the same; for if a lawless state of things existed his property would be in danger from the incursion of some kindred, untamed spirit, or he might pursue a course of recklessness, going on from bad to worse, until his life instead of his liberty became the forfeiture, in order to insure protection to the lives of many of his fellow-men.

Such is the influence of laws in a republican government like ours. In monarchies, aristocracies, and hierarchies, they may originate in different causes and result in different effects. But these are not to our purpose, and we sincerely hope that experience will never teach, in our country, any thing of their appropriateness.

Laws then being made and enforced for the gene-

ral good, it may, with all reasonable propriety be asked, from whence shall we derive our lawgivers and magistrates? That we, as a free people, choose them from among ourselves, is certainly a fact;—but are they judiciously selected—taken with the greatest regard to general good, or are men actuated by fictitious and mistaken principles with regard to these things? Now it appears to us that the question is of very easy solution. Legislators should, in order to establish good and wholesome laws, not be taken from any one class or profession of men, but from the body of the people, whether they be tinkers, basket-makers, tanners, lawyers, physicians or farmers. The reason is obvious: there can be no individual engaged in one profession and know what is for the general good of another, so well as a member of that particular fraternity. Nor can an inhabitant of one town legislate to the needs and wants of another, so well as an individual who may have long resided there and become acquainted with its own peculiar circumstances. In New England—in the United States, the mass of population is, and forever must be farmers; for it is in vain to suppose that a nation can exist when the number who cultivate the earth fall in the rear of those engaged in commerce, manufactures and the arts. And it is equally vain and preposterous to suppose that the number of free white laborers, not servants but lords of the soil, will not increase in as great and greater ratio as that of all other callings put together. The great west with its fertile prairies says it will be so; and the south, the sunny south, from her hearts as pure and mild as her own skies, will send up a voice on her spicy breezes saying, the bonds which our fathers fastened on the sons of Africa, in due time shall be loosened, and the slave shall go out free, never to water our soil with his tears or sweat any more, and our hands shall labor and our hearts shall not faint: we will build up our waste places and set hedges round about them, lest strangers enter in and spoil our land.

If farmers are, or are to be the mass of the State or nation, they should by right of majority, by right of interest, and by right of sympathy, (for they must know, if they know anything, what the rights of the people require.) lift the highest voice in the councils of state and national deliberation, and they should choose their governors from among themselves and their counsellors from the people, and not send men of other trades to be the proxy of their wishes. And here an argument we have heard employed very often, if not a thousand times, comes up to veto our doctrine—for how often have we heard it said that "farmers don't know enough to make laws." Wherein the code by which New England is governed now is better than it was in the "Spartan days" of the pilgrim fathers, is a something we shall not attempt to unmysticize: we are quite sure, however, that the laws of modern times are strangely removed from their ancient simplicity: but "farmers don't know enough" (strange reflection on New England husbandmen! but stranger that they will be gulled by such a doctrine) to make laws." This is the very point to which we would call their attention: for if they do not know enough to make them, how can they judge of their workmanship when done?

Now every farmer should know enough of the science of law, the principles which regulate its movements and establish its effects, to know when good and wholesome laws are made, when they are carried into their proper effect, and more, that Cin-

cinnatus-like, he may at any time be able to leave his plough and hasten to the councils of the nation. As long as such a state of things exists, our country may be safe. While the voice of the people, the whole intelligent people is heard and regarded, foreign and domestic evils, though they may roll in like a flood, will meet with a reacting influence which will hasten back their anger-kindled waves to deluge and clog the fountains from which they sprang. Let the people of the United States become an ignorant people, heedless of their laws and their rights—let them cease to act on those principles of equity and independence—under which their fathers acted, and a degeneracy will spring up which will overshadow the land with its abominable branches, sapping as it grows the lifeblood of our constitution and laws, and ere another half century has recorded its deeds on the page of history, it will be written of ours, the last and noblest government of earth, what tyrants would have written every where, that there is not virtue enough in men to govern themselves. United America, with her territories stretching from the Atlantic to the Pacific, from Niagara to the gulf, with her constitution based on principles of general equity, and the corner-stones of her union cemented by the blood of her fathers, a noble band, has fallen, no more to have a name and place among the nations of the earth. W. B.

Mount Osceola, May 25, 1840.

PROGRESS OF VEGETATION DURING THE MONTH OF MAY, 1840.

(Communicated for the N. E. Farmer.)

May 2. We have had three rainy days during the week, Monday, Wednesday and Friday, and the weather has been rather cold wital. The Isabellas on the back wall of the grapey have made shoots six inches in length, all of them showing two and three bunches of fruit. The vines upon the rafters, Hanburs, Sweetwaters, Linfindal and Rose Chaselsas, have all burst freely and made shoots two or three inches long. Early peas planted on the 6th April, and radishes and onions sowed on alternate rows the 16th April, are all up finely. Chenango potatoes planted on the 4th April in a frame, are up four or five inches, and I intend to transplant them to the field on Tuesday. Cherries, plums, peaches, and generally pear trees are in perfect blossom, and the horse chestnuts and mountain ashes are leaved out greenish, indicating an early spring.

May 3. Since Sunday last the weather has been uncomfortably cold. On Monday and Tuesday, it rained almost without intermission. The wind has blown raw and cold from N. N. E., and today the chilling blast has reminded us most forcibly of winter. Planting progresses but slowly: we have transplanted the sprouted chenangoes from the frame to the field; have planted early corn, several hills of cantelopes under glass frames, two beds of carrots, and have finished planting potatoes, (Dillinghams, Kidneys and Rohans.) The vines have advanced but little since Saturday.—Fruit trees are all in perfect blossom. Apple trees in sheltered situations commenced blossoming on the 3d inst.; and I observed yesterday the horse chestnut tree near the Marine Hall in blossom.

May 16. The weather has been bright and clear, with but little easterly wind since Saturday: a fine shower commenced yesterday afternoon at 3 o'clock, which continued with slight intermissions into the

evening. Farmers have generally availed themselves of the fine season to plant potatoes, and we have sowed during the week carrots, parsnips, beets, peas and beans, and have planted a dozen hills of canteloupes and water melons. We have also finished transplanting strawberries, the old beds of which are blossoming freely, and have staked and tied up the raspberries, which are very heavy with foliage. Early potatoes planted on the 6th April are all up distinctly upon the rows, while chennagoes planted at the same time, are just breaking ground. Blossoms upon fruit trees are most profuse: the apples in particular, present dense masses of flowers, and several of the smaller kinds, as plums and cherries, are already setting their fruit, of which there is at present the prospect of great profusion. The vines in the graperly have grown surprisingly within the last three days, and I have tied down the greater part of the spurs, both upon the back wall and rafters. Thus far the *Rosa Chasselas* has made the strongest growth, next the Hamburgs and Sweetwaters, and lastly the Zinfindal, which has always pushed slowly with me, and requires a long season to perfectly mature its fruit.

May 23. On Sunday and Monday last, the weather was intensely hot. Mr Ives's thermometer, in an exposure similar to that of the late Dr Holyoke's, which was considered for so many years as standard authority, indicated 94° at one o'clock on Monday. Such a great degree of heat induced necessarily a rapid and vigorous progress in vegetation; but since Tuesday morning, the sky has been the greater portion of the time overcast, the wind has blown raw and cold E. N. E., producing what has been familiarly termed "a dry storm." The season of blossoms has nearly or quite passed away, fruit of all kinds having set most abundantly, and if our trees are spared from the ravages of the canker-worm and the caterpillar, we shall be favored with a most abundant harvest. The yellow locust trees are just leafing out, and mountain ash trees are blossoming beautifully. Canteloupes planted on the 9th inst. under the hand glasses, are all up finely, but have already suffered some from the attack of the melon fly, and we have this evening sprinkled them freely with dry sulphur, having first watered them copiously. I have generally found this application very effectual in ridding the vines of bugs and insects of every kind, and have sometimes fancied that it has a tendency to promote the growth of plants. During the week we have hoed our early peas and early potatoes, and have planted mangel wurtzel, beans, melons, squashes and pumpkins. Early corn planted on the 8th, and peas and beans planted on the 11th inst., are all up finely upon the rows. The display of tulips has been very magnificent during the week in the gardens of amateurs. Mr Cabot's bed, containing 1470 bulbs, was at its height of beauty yesterday, and some few of the earliest are partially faded today.

May 30. Since Sunday last, which was a cold easterly day, on which we were obliged to kindle fires both morning and evening, the weather has been remarkably warm, reminding one more of "Independent" than of "Election" week. Vegetation of all kinds has advanced most rapidly under the influence of a scorching sun, which has been, however, too powerful for light soils, which begin in many places to feel the effect of drought, so much so, that at Ellingden we have found it necessary to use water freely upon the grape border, and upon newly transplanted trees. The season of blossoms has quite passed away, and fruit trees have

set very full and strong, with the exception of pears, the fruit of which is apparently much injured by a mildew or blight, similar to that which frequently appears upon gooseberries. Some persons attribute it to the intense heat of Monday, 18th inst., while others fancy it may be caused by the sudden changes from heat to cold, which however have not been so great as in former years, the entire month of May having been remarkably free from frost. The crop of apples will apparently be most abundant. The fine weather has been most favorable to the growth of the vines, and the *Isabellas* on the back of the house are in perfect blossom, perfuming the graperly with a delightful fragrance. The operations of thinning the bunches, of which I have cut out two out of three, of shortening in the fruit spurs, and of training the new wood for another season, has furnished me constant employment each morning and evening during the week, and if we can preserve the vines from mildew, the crop will be very fine. We have hoed for the second time, all our early potatoes, which never promised better at this season; I have hoed our early corn, which is up three or four inches, looking very healthy and green, and have pricked out our celery plants from the frame to be transplanted to the trenches early in July. Peas planted on the 6th April are in perfect blossom. Potatoes planted on the 8th, and beans planted on the 11th inst. are all up finely, and we need only a rainy day or two, to enable us to rank this as the most favorable season for vegetation that we have enjoyed for several years.

ON STRIPPING COWS.

Winter Product of a Devon Cow.

Every milkmaid has been cautioned that the last milk yielded by the cow at any one milking, is richer than that which is first obtained—but this is not the only consideration which shows the importance of thorough milking. The more there is left in the udder, the less will the cow give at subsequent times, and the sooner will she "go dry." After once going through the cow-pen, the milk-woman or man, (for in New England the men milk the cows,) ought to be compelled to go round again and completely strip each cow.

The importance of this will be better understood if there be truth in the statement which we have lately read, apparently on good authority. We confess we were not prepared to believe that the difference was so great as there stated, between the first and last portion of the one milking. The statement is that

"Several large coffee cups having been successively filled from one cow, till she was quite dry, the following results appeared, great care having been taken to weigh the cups when filled, to ascertain that they held exactly the same quantity.

In every case the quantity of cream was found to increase in proportion as the process of milking advanced. In different cows the proportion varied, but in the great number, the excess of cream in the last cup as compared with the first, was as sixteen to one! In some it was not so considerable, therefore as an average it may be called as ten or twelve to one.

The difference in quality of the two sorts of cream was no less striking; the cream given by the first drawn milk was thin, white and without consistency; while that furnished by the last was thick, buttery, and of a rich color."

In the Philadelphia Farmers' Cabinet, we have

the winter produce of a Devon cow: "Abraham P. Holdrich, of Spencerstown, Pa., had an accurate memorandum kept of the butter made from a Devonshire cow, which calved last autumn. The result was, that from the 10th December to the 10th January, including both days, there was made from her milk 56 pounds of well worked butter—nearly equal to two pounds a day. The cow was fed with roots, hay and buckwheat bran. Estimating it at 25 cents a pound, the butter made in the depth of winter was worth \$14, and if we consider this the average product of eight months in the year, the aggregate amount for that period would be \$112."

This shows the importance of keeping a good breed, and of keeping it well: like cultivating rich land instead of poor, it takes no more labor to milk and take care of a good cow than a bad one.—*American Farmer.*

From the Albany Cultivator.

SUCCESSFUL FARMING.

Messrs Gaylord & Tucker—I think I have been very successful in farming the last year, and will give you an account of the different crops I have raised, and their product from 39 acres of limestone land. I do not mean to boast of raising more from an acre than other farmers, or of having raised any very superior crops; but on the contrary I am aware of having committed many errors in my system of farming, and am convinced that my crops last year ought to have been one fourth heavier, and that in future I shall increase the product from year to year above what I have raised last year.

Yours, respectfully,

FREDERICK SEITZ.

Easton, Pa., March, 1840.

Dry rot may often times be prevented in living trees if the wounds are carefully covered with a composition made of resin, tallow, bees wax, and ochre melted and mixed well together—and where it is necessary, for want of time in the spring, to resort to winter trimming, this method of prevention should be resorted to. It is cheap, simple, and adheres to the wood excluding moisture until it is healed over.

Every person who has anything to do with cooking ought to know, that when water is once made to boil all that is further necessary, is just to keep it up to that temperature; any additional fuel added is wasted, for water heated in an ordinary culinary vessel, cannot be made more than boiling hot.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JUNE 10, 1840.

AGRICULTURE IN MASSACHUSETTS.

In a former number we made some hasty remarks on this subject; and these remarks we shall continue in this case, not intending at this time to discuss the subject fully or elaborately. This duty we reserve for another occasion and place. But a few cursory hints may be of use if they keep the subject more and more before the public mind; and induce the intelligent and reflecting to look at it in its various important relations.

There are no natural and inherent incapacities in Massachusetts, which forbid her agriculture becoming a profitable and commanding interest. Every one admits her extraordinary success in commerce and manufactures and the mechanic arts. Her commercial marine is the second in the union; and indeed a large part of the commerce of New York is owned and navigated by New England men and equipped and sustained by New England capital. In manufactures and the improvement of the mechanic arts, she is in the rear of no State in the Union; and taking into the account the amount of her population and territory, she may challenge a competition perhaps with any of the older countries of Europe. Her fisheries, her commercial profits, the increased value which her manufacturing industry gives to the raw material about which it is employed, add essentially to her wealth; and with an inflexible determination to maintain a sound currency and a healthy and safe system of credit, there is no reason why she should not become one of the richest, and continue, as we believe she now is, one of the most prosperous communities in the world.

The extent of her agricultural interest has not yet by any accurate examination been ascertained. It is much to be regretted that this has not been done; or at least that measures have not been put in a train to accomplish it. The approaching valuation of the State, which takes place once in ten years, and which in course is to be taken the present season, will do something towards it; but these returns can be considered only as an imperfect approach to exactness, because there is a natural effort on the part of those who make them, to make them as low as possible. This was formerly the practice with a view to avoid the payment of the State tax; and though no State tax has been levied for several years, yet men still act under the same influence, and make the smallest returns they conscientiously can, where conscience has any thing to do with it, lest they should be rated too high in the valuation and assessed accordingly in the taxes of their own town.

It is believed, however, that could any thing like the same fullness and exactness be exerted in obtaining statistical returns of the agricultural products of the State as have been exerted in obtaining the returns of her commercial enterprise and her manufacturing industry, the results would be highly gratifying, and much transcend the calculations or opinions generally entertained. Yet on the other hand it must be admitted, that not a sixth part of our soil is cultivated which is capable of profitable cultivation; that of that which is cultivated by improved husbandry the products might be almost quadrupled; that we have no agricultural products for export; that our imports of agricultural products are very large; that we do not supply, excepting to a very small extent, our own bread, butter, cheese, beef, pork, mutton, potatoes, hay, oats, corn and rye; and that in truth little or

no capital is employed in agriculture, in the way in which it is employed in trade or commerce. We do not like to make these concessions; and yet we must make them. We believe that if Massachusetts were walled in by a barrier as impassable as the walls of China, she is perfectly capable to support in comfort and luxury from the products of her own soil, a population four times as large as she now has. We believe it would be for the interest, happiness and morals of her people, if she were driven to the stern necessity of doing it. But calculations of any such issue or condition would be perfectly idle, while so many other resources or occasions for the application of labor and capital present themselves, affording the opportunity of an immediate and apparently a much more liberal return.

The island of Nantucket, regarded as it commonly is, as a mere sand bank in the midst of the ocean, to be beaten by waves and swept over by the cold winds, can scarcely be said to have admitted a plough into its soil; and yet there cannot be a doubt that its agricultural capacities, if properly brought out, are sufficient to maintain, without any foreign dependence whatever, a population three times as great as it now has; but what can be expected while oil retains its present price, and from men trained to think no pursuit manly or spirited but the pursuit of whales over the whole Pacific; and whom you might as well expect to keep quiet when they hear the blowing of a sperm-catch, as to keep a race horse still when he is brought out upon the ground where he has won many a plate.

What we have said of Nantucket is true of other parts of the State; and the general rush of our young men into professional pursuits, or the pursuits of trade and commerce, in our cities, seems almost fatal to the hopes of any great advancement of our agriculture. Yet facts upon facts, observation, and experience have satisfied us, that in an assiduous, skilful and well conducted agriculture, even in Massachusetts, the chances of obtaining a comfortable livelihood and an honorable competence, are as favorable as in any pursuit to which the attention can be directed.

We have already alluded to one great hindrance to agricultural success in Massachusetts, and that is the fact that no capital, properly speaking, is ever applied to it. With the exception of the small amounts used by our Connecticut river farmers, which they generally borrow for six months, for the purchase of stock in the fall to be stall-fed and turned off in the spring, we hardly know a case in which a farmer thinks of employing any capital in agricultural operations and improvements, beyond what his own scanty means supply. The idea of borrowing money with a view of cultivating twenty acres of his farm instead of five, and thus quadrupling his products without quadrupling the expense by which they are produced; or in order to redeem a bog-meadow which now yields him no valuable return, but which by a judicious system of draining, might be rendered eminently productive, is an enterprise which would hardly occur to him—which often he has not the courage to undertake, or which if he should undertake, his neighbor would be loud in condemning his rashness in thus involving himself in debt. To expect success in agriculture without a judicious expenditure of labor and capital, is as idle as to expect success in trade, or commerce, or manufactures, or any other conditions.

H. C

LABOR-SAVING MACHINES.

We have recently seen a field of six acres of corn planted in two thirds of a day with perfect exactness, by a machine drawn by a pair of mules driven by a boy, and the machine held by a man; and at the same time

by the same machine the same field was manured with twenty-five bushels of pondrette, evenly dropped in the drill. The calculation was to make the drills four feet apart; and to plant the corn 18 inches in the drill, 3 kernels in a hill, with the intention of removing one and leaving two to be matured. The machine was adapted to the planting and sowing every other variety of seed, even to the smallest, and with like exactness. The machine worked well; though we think it might have been made less cumbersome than it was; but it is not our intention at this time to describe it or compare it with others. The boy, if the mules had been well broken, might have been dispensed with, and the whole performed by one man. And this, upon the old system of planting, furrowing, tiling, manuring in the hill from a hod, dropping, and covering, would have been equal to the labor of eight men. The machine could be built for ten dollars cost. Now what an immense saving of labor has been effected by this arrangement! yet men will tell us, with as much braggadocio and self-complacency as their waistcoats will contain without bursting the buttons off, that they want none of these *new-fangled notions*; they choose to go on in the *old-fashioned way*, as though the old-fashioned way was of course to be always the best way. Now the old-fashioned way was to wear undressed goat skins, sewed together with strings of birch bark or punned with thorns; to set on bare ground; to bake your dough in the ashes; to dip up your porridge in a wooden bowl or a broken gourd, and to eat it with a clam-shell. Why cannot we go back to these blessed times of our great grandfathers, who were no doubt so much happier and so much wiser, and so much better than we are. Alas! for the sad degeneracy of modern times; and the unhappy discovery, (no doubt the effect of some diabolical agency,) of balancing a meal-bag upon a horse's back, without putting the meal in one end and a stone in the other! H. C.

ACKNOWLEDGEMENTS.

We acknowledge the receipt of a package of the seed of the Cotee or Indian Bread Root, from H. L. Ellsworth, Esq., of the patent office, Washington. The Bread Root is used for food by the Florida Indians:—Whether it will endure our climate or be of any use to us, remains to be proved. The seeds in question were handed to the President of the Mass. Hort. Society, and by him distributed among the members, who will do their best to ascertain the merits of the plant.

We have received a miniature map of the State of Maine, just published by Nathl Denbarn, 53 Washington street—one of the neatest and prettiest things of the kind we have ever seen. There are more towns laid down on it than on any other map of the State ever published. The boundaries designated by the treaty of 1783, and the lines of division given by the king of the Netherlands and that claimed by Great Britain, are also accurately laid down.

We have been favored by a friend, with a specimen of refined maple sugar, manufactured by Mr Hosmer, of St. Johnsbury, Vt. It is very white and clear and equal to the best Havana sugar. J. B.

Massachusetts Horticultural Society.

EXHIBITION OF FLOWERS.

Saturday, June 6th, 1840.

Messrs E. Wight, of Dedham, and E. Weston, jr. and F. Parker, of Boston, presented a large collection of native flowers.

Bouquets, by Messrs Carter, Bowditch, Huvey, R. Howe and S. Walker.

Cut flowers from Jno. A. Kenrick, Newton; Scotch Lybournam, (fine) several specimens of Azalias, roses, and other flowers.

Dahlia, by Thos. Lee and M. P. Wilder, Esqrs. The specimen of Ophelia by Mr Wilder, was very fine. We should be pleased to see other specimens of Dahlia repens, exhibited by Mr Lee.

For the Committee.

S. WALKER, Chairman

EXHIBITION OF FRUITS

Saturday, May 23, 1840.

From J. P. Cushing, Esq. by D. Haggerston; splendid specimens of the following select sorts of Grapes: Royal Muscadine, Black Hamburg, White Sweetwater, Golden Chasselas, and Grizzly Frontignac.

For the Committee.

E. M. RICHARDS.

NOTICE. The exhibition of Præmies for premium, will take place at the Mass Horticultural Society's rooms, on Saturday next, 13th inst. Per order, Boston, June 6th, 1840. S. WALKER.

W's favor shall have a place in our next.

BRIGHTON MARKET.—MONDAY, JUNE 8, 1840

Reported for the New England Farmer

At Market 240 Beef Cattle, (including 60 unsold last week) 20 pairs Working Oxen, 40 Cows and Calves, 250 Sheep and 520 Swine. 50 of the above Beef Cattle were from N. Y. Market and 50 more are expected next week. 50 Beef Cattle unsold, all of which are of the first quality.

Prices.—Beef Cattle—A further reduction was submitted to and we reduce our quotations, viz: A few extra, \$6 70. First quality, \$6 50 a \$6 75. Second quality, \$6 00 a \$6 50. Third quality, \$5 50 a \$6 03.

Working Oxen—A few sales were effected, \$70, \$85, \$90, and \$110.

Cows and Calves.—"Dull." Sales \$20, \$25, \$27, \$33, \$35, and \$37.

Sheep—We quote lots at \$2 25, \$3 00, \$3 50 and \$4 00.

Swine.—All at Market sold. Large shoats, to peddle, 4 1-2 for sows and 5 1-2 for barrows. Small pigs 6 and 6 1-2. At retail from 5 to 7 1-2.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northern exposure, week ending June 7.

They would respectfully call the attention of Dealers and Agriculturists to the above assortment, which consists of many of the best kinds now in use, and which they are prepared to sell at the very lowest prices.

JOSEPH BRECK & CO.

New England Agricultural Warehouse and Seed Store, 51 & 52 North Market Street.

May 20.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and horse, with a boy to lead, will rake on an average from 25 to 30 acres per day, with ease, and do the work well. They are coming into very general use in all parts of the country, and will, no doubt, in a few years, supersede the use of the common hand rake. There is a great advantage in this rake over all others, as the person using it does not have to stop the horse to unload the rake.

GRAIN CRADLES.

The Grain Cradle is an article which is coming into very general use in the New England States, where they were till of late but little known, although they have been in very general use in the southern and western States, for many years, and which is found to be decidedly the best mode of harvesting grain, as it is supposed one man will cradle five acres in a day when he cannot reap more than one. The difference in gathering a crop is so much in favor of cradling, that we must suppose that it will be the only mode adopted hereafter, and the grain cradle will become of as much use as an implement of husbandry, as the plough now is.

There has been a very great improvement in the manufacturing of this article, they are now made on the most improved plan; the scythe is well secured and finished in a superior manner and made of the best cast steel.

CARNATION SEED.

The Subscribers have received from Rotterdam, a small quantity of extra fine Carnation Seed, saved from one hundred choice varieties, which they offer at 25 cents per paper. We have tried it, and find that it vegetates freely. It cost us 30 guilders per ounce, and from the representation made, no doubt will give satisfaction to those who may be disposed to try it. We have also very fine carnation seed at 12 1/2 cents per paper. The seed may be sown with good success any time in May or June. JOSEPH BRECK & CO

May 20.

FOR SALE.

For sale a fine heifer Calf, from one of the best cows in the country, and by the celebrated Ayshire bull imported by Mr Cushing. Inquire at this office, or at Winships' establishment at Brighton. May 20.

PURE BLOODED STOCK.

For sale, three young Bulls, 7 to 9 months old, from improved shorn horn Durham, Alderney, and North Devon Stock. Inquire at this office. April 29 61

GARDENERS KNIVES.

JOSEPH BRECK & CO. have this season imported and now offer for sale a few very superior Garden Knives, for prunning, &c. manufactured expressly for Gardeners, and warranted superior to any article of the kind here imported.

Also—a large assortment of Budding Knives, Grape Scissors, &c. &c. April 22.

(Continued from page 406.)

Today I made my first acquaintance with those abominable sloughs for which Illinois is notorious. Just as we reached the ten mile house a hard rain set in, and we were obliged to stop and make the best of wretched accommodations.

The next morning was cloudy and so cold that we had to wear cloaks, although it was the middle of June. We travelled four miles over the prairie, when we came to a belt of timber and found six miles of the worst road I had yet seen, if road it may be called, for in this State no labor is done upon the road except to build corduroy bridges over sloughs that have become impassable. In the midst of this timber there is a little hamlet of log cabins called Independence, though as well known in the vicinity by the name of Pin-hook. This town, as it is called, contains two stores, and, what is an uncommon sight, a school-house. About a mile from town we came to the Embarras river, and as the ferryman lived half a mile on the other side, we found ourselves in an embarrassing situation.

Here we found six wagons and as many families of emigrants from the east. The men were cutting fuel, watching their horses that were grazing, &c. The women were washing, cooking, and arranging their goods, while the children, in the happy carelessness of youth, were paying all manner of pranks upon the river banks: the whole forming a capital scene for the pencil. I entered into conversation with these people and found them from different parts and bound some for Sangamon county, some for Missouri, and some for, they knew not where, only they were going west, and I thanked my stars that I had not been mad enough to bring my family hither, but that they were then enjoying the comforts of home.

Having at last got the ferryman down to the river, we crossed over and stopped at the first farm house: this is in Coles county.

The next morning we saw several wagons moving east, and as it is as much a custom to inquire where one is bound, where from, and to ask other similar questions, as it is for ships at sea to speak each other, we were soon acquainted with their history. These people had been some to Warren county, on the Mississippi, and others to Iowa territory. They had all been sick, and had lost many of their kindred by death; they had sacrificed their property, and, poor and disheartened, they were almost begging their way back to the east. This group and the one we saw yesterday are specimens of what may be seen daily on all the great routes in the west.

We took leave of our host, who was a jolly Kentuckian, after breakfast, and pursued our way over level prairie, so soft that our horses tracked deep at every step, but no sloughs. We had to ford one creek about three or four feet deep, and at the end of 20 miles we came to the Great Okaw, a narrow sluggish stream, which we crossed by a ferry, and as it was 16 miles to the next timber, we put up, for it is impossible to travel in the night, and the traveller must seek a shelter before night or camp out, which, for a person unprepared for it, is no joke.

Early on the following morning, we started in company with two other wagons from the east, and travelled over low prairie, and were obliged to go through three sloughs of the "biggest kind," each nearly, and one of them more than a quarter of a mile wide. I was obliged to wade and lead my

horse in water up to my hips, and fortunately got through without assistance, while my fellow travellers were obliged to hire an ox team to haul them through. At 6 o'clock we reached the Little Ohaw, which we crossed on a rude bridge, and put up, having consumed the whole day travelling 16 miles, and we were very diligent too.

In the morning we parted company with our fellow travellers, who kept the road to Springfield, while we turned off north towards Decatur, and having reached there we concluded to tarry until the next day. Decatur is built upon a broken piece of ground, on the north side of the Sangamon river, (which is here about 50 yards wide,) 35 miles above Springfield, and is the seat of Macon county. It is full of stumps, has a few good houses at respectable distances, and contains about 200 or 300 inhabitants; but being the only town in the county, it has considerable trade and may become an important place. Here for the first time, I saw an ox mill for grinding corn: afterwards saw many of them. The construction of them is simple: a circular plane is made of plank, with a shaft in the centre from which it is braced: the shaft is inclined 15 or 20 degrees from a perpendicular, which gives the plane the same inclination to the horizon, and the gearing is on the periphery of the plane or platform, and upon this from two to six oxen are placed, according to the size of the mill, who put the machine in motion. It is the simplest kind of tread-mill.

We left Decatur early by the northern road. It was a splendid morning: the air was clear, the sky cloudless, and the prairie here higher and more rolling, the road was dryer and better than any we had seen for a long time, and we rode on in high spirits. About 9 o'clock we came to an impassable creek, and supposed that we had misunderstood the directions we had received in town, and were out of our way—a misfortune to which travellers are very liable, for most of the inhabitants are new settlers and quite ignorant of the geography of their own neighborhoods, and those who do know anything about it are as bungling as the sons of Erin in giving directions. In our dilemma we turned towards the head of the creek, hoping to strike the proper track in that direction, and after travelling until noon without finding any other track or making any progress in our way, we came to a halt. The creek where we then were, though broad was fordable, being only about two feet deep. The grove where we entered the prairie was just discernable, and we could see timber upon the other side, at the distance of from 10 to 15 miles. We did not like to go back and we knew not the way forward. My companion had a pocket compass and map, and with the assistance of these we ventured to proceed. Having taken the bearings of the grove we had left and of our track, we computed our departure as accurately as we were able, and laid down our course; then crossing the creek we travelled by the compass over the trackless prairie until late in the afternoon, when we struck the timber within a few rods of the road we should have travelled. We had then five miles to travel over as bad a road as was ever travelled, to get to Clinton, a new town on the north side of Salt Creek, which stream we crossed upon a bridge very much like the roof a Dutch barn, and near which we got stuck in a mud-hole from which it took us an hour to get out. I never before realised the extent of the misfortune of those who get *raved up Salt creek.*

It was not until past 8 o'clock that we got to quarters, fatigued and hungry enough to make very indifferent accommodations agreeable.

(To be continued.)

THE WHEAT FLY.—When there is an abundance of clover or hemp around a wheat field, it has been ascertained to a certainty, that very much less injury will be done to the wheat by the grain flies, than in most other situations.—The reason is plain. The weevil deposits its egg on the sweetest plants it can find, and prefers the clover or hemp even to wheat.

Might it not be a good plan for farmers, whose wheat fields do not happen to be situated in the midst of a clover field, to sow a pretty wide row of hemp around the outside of the lot forthwith.—*Maine Cultivator.*

APPLES, of this year's growth, the first we have seen, were selling in our market yesterday at twelve and a half cents per quart!—*Baltimore Sun.*

HOT CORN.—New corn made its appearance in the New Orleans market, on the 8th ult. Ours isn't quite fit to eat yet.

SILK SILK WORMS EGGS—\$5 PER OUNCE.

The Eggs of the celebrated *Sina Silk Worm*, now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The *Sina Silk Worm* was introduced to France from China by Louis XVI. in 1784, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France.

Each sheet contains an ounce and is signed "Camille Beauvais."

WILLIAM KENRICK, Newton.

Or apply to JOSEPH BRECK & CO. March 25. ept

BUSSA MULBERRY SEED.

We have recently received 50 lbs. fresh Broussa Mulberry seed, which we offer by the ounce or pound. March 11. JOSEPH BRECK & CO.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

Orders for Bone Manure or Oyster Shell Lime, left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

March 4, 1846.

WANDERINGS IN THE WEST IN 1839.

No. IV.

(Continued from page 412.)

Clinton is a town recently laid out, contains ten or twelve houses, and is the seat of De Witt county; put the two together and we have De Witt Clinton. It is needless to say that the projectors are Yorkers, and have displayed a rare specimen of American ingenuity in naming towns and counties. Proceeding north, the prairie becomes morrolling and the road better. We passed through two or three belts of timber, in one of which I saw a quantity of stable manure placed along in the road, as we in the east would use gravel, probably because it was less labor to put it there than to cart it out upon the prairie. At the end of 25 miles we came to Bloomington, the seat of McLean county, situated on the edge of the prairie on the north side of Blooming Grove. This is a pleasant, thriving town, containing several good buildings: it has three steam mills, a number of stores, two taverns, and there is the appearance of a good deal of business: lots in town are held at high prices, and timber land in the grove is valued at from twenty to thirty dollars an acre. Many of the inhabitants are from New England. We spent the remainder of the day and the night at Bloomington, and the next day took the road towards Peoria. We found a very good road through a fine tract of country—rolling prairie and timber alternating, and a pleasant ride of twenty-five miles brought us to the village of Macinaw. While there we had a heavy shower, and after crossing Macinaw river we were overtaken by another hard rain, which compelled us to stop at the first house we came to. I speak of houses, though properly speaking there is very seldom any thing but a log cabin in the country, except in the towns, and there even the greater number of buildings are often cabins. The shelter we obtained this night was in fact a cabin of the "worst kind," but our situation made it as acceptable as a palace would have been in other circumstances. The next morning was cloudy, cold, and uncomfortable: we resumed our journey and three miles brought us in view of Tremont, the seat of Tazewell county. We passed the town at the distance of about a mile, and I regretted that we did not take the road through it. After we crossed the Macinaw we began to discover gravel in the hills: the road is generally better, and the water is more palatable than that which we found before. The groves in this vicinity are chiefly white oak and hickory, and as we came near the Illinois river we found a good deal of clay: the road down the bluff is very steep and dangerous. We crossed the river about one o'clock and entered Peoria.

Peoria is beautifully situated on the west side of the river, which at that place makes a bend to the eastward, something less than a semicircle: the bluff comes near to the river, and is covered, as is the narrow strip of bottom land, with a thick growth

of timber: on the west side the ground rises gradually to the second bottom, an elevation of twenty or thirty feet, and the town is principally built upon this ascent: the second bottom extends back to the bluff something more than a quarter of a mile: there are a few scattering trees on the face of the bluff, and on the top of it are a few houses commanding a fine prospect of the town, ten or twelve miles of the river, and the surrounding country. The prairie stretches back from the bluff a mile perhaps to a belt of timber. On the whole it is the finest site for a town that I ever saw. Peoria contains 1200 inhabitants, 3 taverns, 25 stores, 1 printing office, and Mr Huntoon, favorably known at the east, has established a school there which succeeds well, but though the place is pleasant, it is very unhealthy.

After a sojourn of two days we took leave of Peoria, and recrossed the river four miles above the town, into Tazewell county. Soon after a hard rain set in, and we got most thoroughly wet again, and we found no stopping place until we got to a place called Partridge Ridge, 12 miles from Peoria. Here we found comfortable accommodations, and concluded to stop a few days and look about the country. Accordingly the next day we rode around the neighborhood some ten or dozen miles, and called at several farms, among others at that of Mr Buckingham, who had been in the country seven years, has a very large estate, keeps about 100 head of cattle, besides many horses and hogs. He had in his cribs from 1000 to 2000 bushels of corn, for which he said he could find no sale even at the low price of 18 3/4 cents. Winter wheat does not succeed well in this neighborhood; spring grain does well, but corn is their principal crop, and cattle and hogs are their only resource to obtain money. Farming is done in a slovenly manner, labor is high and not easily obtained: female labor hardly to be gotten at any rate. There are no public schools and private schools are rare.

We made another excursion across the prairie eastward to Walnut Grove. On the prairie we passed half a dozen houses which had a desolate appearance and upon inquiry I found that it is the town of Hanover, which contains not a single inhabitant—the last family having moved but some months before, and the post office which had been established there was removed about three miles to a sawmill in the grove, because there was no person left in town to serve as postmaster. At walnut grove we called at the house of a Mr Curtis and went over his farm. I saw there several pieces of English grass, or as it is called in the west, *tame grass*, and I observed that some of it looked better than the rest, and Mr Curtis's told me that it had been manured. He uses manure upon all crops, although his prairie is of the best kind, and I saw a great difference between the crops that were manured and those that were not. The prairie will not produce good crops of grass without manure, and Mr Buckingham told me the same.

A heavy rain kept us within doors on the third day, and the next we rode to Mr Buckingham's and tarried over night: our fare here was simple

but abundant, and we were treated with genuine hospitality. The evening was passed in pleasant conversation before a bright fire, which blazed cheerfully in the huge stone chimney. Although it was near the last of June, there had been scarcely an evening when a fire was not agreeable, although the day might have been very hot. In the morning we left our host and travelled in the direction of Peru. The country about Crow Creek, which we passed in the forenoon, is very fine: the land is rolling, alternate prairie and barrens, affording some splendid views: the bed of the creek is of pebbles and the water is clear and sparkling.—Oxbow prairie is also very pleasant: we saw there plenty of apples and peaches. North of the Oxbow prairie we came to a little town called Magnolia, containing about twenty houses. About a mile from town we stopped for the night at the house of a Mr Hawes, who was the first settler in this part of the country. He is located in the edge of the timber near a fine brook, and is the wealthiest man in this neighborhood.

Our route the next day was over prairie about fourteen miles. We then came to barrens, where we had a bad winding road down to the river, which we crossed with difficulty and entered Peru.

Peru is at present a small town of about 300 inhabitants. It is built principally upon one street at the foot of the bluff, but being at the head of navigation at low water, and the termination of the canal from Chicago and of the railroad to Dixon's ferry, its prospect for future prosperity is flattering. Leaving Peru we followed a deep ravine in the bluff and came upon the prairie back of the town, where we lost our way, and darkness overtook us upon the open prairie, where we were obliged to pass the night without provisions or a bed; and with bad lodgings, empty stomachs, and mosquitoes withal, we had an uncomfortable night enough.

At daybreak we discovered that our horses were gone, and it was not until sunrise that we recovered them and got ready to start, and after wandering some time we got upon the right track and rode to Homer, 10 miles from Peru. Homer is a small town near the Little Vermillion river, in La Salle county: the day was extremely hot, and we stopped awhile and then rode on four miles to Troy grove. The country around the Little Vermillion is very beautiful, the soil is first rate, and the water good: but yet I was told that it is unhealthy.

The next morning we left Troy grove and entered upon the wide prairie, where wood and water are seldom found:—eight miles brought us to Four mile grove, where we found an excellent spring; thence to Pawpaw grove is six miles. The prairie here is quite high and rolling, even hilly—and the subsoil is gravel; the groves on the contrary are low and flat, occupying the lowest places where there is water, and are heavily timbered.

Between Pawpaw and Four-mile groves we enjoyed the most extensive view that I ever saw upon land: towards the N. W., S. E. and N. E. in the direction of Chicago, there is nothing to intercept the sight for a distance of perhaps from 40 to 60 miles; indeed as far as the sight can extend, nothing

ing but one boundless field of waving grass with here and there a little grove, which appear like little specks or miniature islets upon this vast verdant ocean. It is a "grand prairie" indeed. In this vast solitude, man with all his powers sinks into utter insignificance:—the beholder is astonished—his thoughts expand with his perception—but they will recur to *himself*, and then he feels his nothingness. The least reflecting man is sensible to the grandeur of the scenery upon the Alleghenies—but here much more so, for the scene is truly sublime.

Four miles from Pawpaw we came to Allen's grove where we stopped for the night, the next house upon our route being sixteen miles. We were now in Ogle county. The land here is not yet surveyed and consequently not in market.

From Allen's our route was to plum grove, seven miles, thence to Brodie's grove, nine miles:—we enjoyed the same unbounded prospect as the day before. As we advance north the prairie becomes drier and more sandy. In the hollows between the swells we found many shallow ponds but no good water in the whole distance. The next house was at Driscoll's grove, seven miles, and fearing that night might overtake us we stopped at Brodie's.

(Continued on page 420.)

From the New Genesee Farmer.

USE OF LONG MANURE.

Much has been said in the Genesee Farmer and other agricultural journals, during the last four or five years, to show the great advantage of using manure in its fresh and unfermented state. It has often been asserted that by the process of fermentation in the heap, or lying in the yard until partially rotted, much of its strength escapes and is lost, that might be saved by depositing it in the ground in its fresh state, there to undergo the process necessary to prepare it as food for plants. This new practice seems to have obtained pretty generally, and the results have proved satisfactory to those who have published them.

Being fond of new things myself sometimes, I subscribed practically, and without further inquiry to this theory, and have for several years used large quantities of coarse manure from the horse stable and yard, in its rank state, and tried it on a variety of soils and crops until I am fully satisfied it is not best for me, whatever may be the opinion or practice of others. I have, in some instances, put from 60 to 70 wagon loads upon an acre of ground, ploughed it under and covered it well, and received but very little benefit from it to the crop the first year, especially if the season proved rather a dry one. Nor could I ever trust to its mouldered remains for a crop the year following, for on ploughing it to the surface there appeared to be but very little substance remaining to benefit a second crop; but like a burnt rag the air dissolves it, and the winds blow it away, and its principle effect has been successive crops of grass and weeds, increasing my labor in hoed crops at least four fold, and entailing a more serious calamity in the multitude of cut worms and grubs to which it gives birth.

I was taught, when young, by an experienced farmer, never to use unfermented manure, especially from the horse stable, for any kind of crop, if other could be obtained; yet it was considered better than none at all, and often valuable to help

corn, potatoes, and some other coarse feeding crops. I have seen corn materially injured by using it in the hulls in a dry season.

For the last four years I have dug into the same pieces of ground, large quantities of coarse rank manure, when preparing my garden for early vegetables, and have always been disappointed in not realizing the benefit I expected either to the crop or soil; and have been surprised, when working the ground, to find so little remains of the liberal dressing of the previous year, and that little, if it had been buried with the spade seven or eight inches, instead of being decomposed, was often dry and mouldy.

Experience has convinced me that half the quantity of manure that has undergone the process of fermentation in the yard or heap, or has become partially rotted while exposed to the weather, will produce the largest average crop, and whether the season be wet or dry, no disappointment will ensue on account of its use.

I am resolved never to use any more in a raw state, unless it be in the potato drill, considering it, as I do, a loss of at least half the value, when compared with that which has been turned over once or twice, and thoroughly fermented in the heap, and prepared for the immediate use of plants intended to be nourished by it, and the seeds of of weeds entirely destroyed.

The greatest advantages I have realized from the use of short, unrotted manure, has been by spreading it on the surface of the ground when prepared for seed, and mixed with the soil, but not ploughed under. In this way it protects the crop in time of severe drought, and in a wet season benefits it more than if ploughed under and covered with more than six or eight inches of soil. After remaining on or near the surface for one season, I think it worth more to turn under with the plough, for the benefit of future crops, than it was in its first state. The experience of every gardener must certainly be against the use of the raw material.

Too much cannot be said in favor of cooking food for hogs, and other stock; and I would as soon feed my hogs with uncooked potatoes as my plants with raw manure. I have tried both, and I think the less in both cases about the same.

A. BRYAN F.

Eric Co. Nursery Buffalo, 1840.

AGRICULTURAL CENSUS, 1840.

We are happy to perceive that this important subject has been taken up in the proper quarter, and that we are at last to have such an enumeration of the agricultural products of this country, as will furnish some safe estimate of the quantity produced, and the districts in which they are grown. In reply to some suggestions made by us on this subject, Mr Deberry, the chairman of the committee of agriculture has kindly forwarded us a copy of the instructions for the use and direction of the marshals and their assistants, from which we find that the following series of inquiries are to be propounded to every farmer. Although there are some products that would be perhaps desirable to render it complete, yet it contains all the most essential items, and if carried out in the spirit in which it seems to have been conceived, it will be a collection of vast importance and value to the country. Had such a census of our agriculture been taken every ten years, the comparison of the tables at different times, would be of the greatest interest,

as determining the increase in the product of our friends, and the districts in which the greatest fluctuations have taken place.

We have one suggestion to make in regard to this matter, which we consider of very great importance. It is this: Let every printer of a newspaper in the country, and all in the cities that print journals for distribution in the country, give a place to the questions which we copy below, and which will be propounded to every farmer in the United States. As it is to be hoped that there are few or no farmers who do not receive some journal, agricultural or otherwise, such a course would be the means of bringing the subject to their notice, and enable them to prepare their answers with greater correctness than they might otherwise be able to do. If every farmer who receives a copy of these interrogatories, would at his leisure sit down, and write against each one the proper reply, not only would the labors of the marshals be greatly expedited, but, which is of more consequence, a greater degree of accuracy would be secured. The marshals will commence in June, and proceed through their districts as soon as consistent with accuracy. The interrogatories refer to the crops of 1839, and to the products of that year must the answers relate.

AGRICULTURE—INTERROGATIONS.

- What is the number of your horses and mules?
How many neat cattle have you?
How many sheep?
How many swine?
What is the estimated value of your poultry of all kinds?
How many bushels of wheat did you grow in 1839?
How many bushels of barley?
How many bushels of oats?
How many bushels of rye?
How many bushels of buckwheat?
How many bushels of Indian corn?
How many pounds of wool?
How many pounds of hops?
How many pounds of wax?
How many bushels of potatoes?
How many tons of hay?
How many tons of hemp and flax?
How many pounds of tobacco?
How many pounds of rice?
How many pounds of cotton have you gathered?
How many pounds of silk cocoons?
How many pounds of sugar?
How many cords of wood have you sold?
What is the value of the products of your dairy?
What is the value of the products of your orchard?
How many gallons of wine have you made?
What is the value of your home-made or family goods?
As intimately connected with these, may be added those relating to horticulture—which are as follows:
What was the value of the produce of your market gardens in 1839?
What was the value of the produce of your nursery and green house?
It is hoped that editors friendly to the cause of agriculture, or who have readers in agricultural districts, will give place to the above interrogations, and invite the attention of those interested, that they may be in readiness with their replies. Let the first effort for an agricultural census of the United States, be met in a manner that shall insure the desirable accuracy of the measure.—*Alb. Cult.*

For the New England Farmer.

CANKER WORM.

MR EDITOR—The increasing ravages of this pest of our orchards, the present year, and its rapid approach to many of us who have not yet been over-run by it, have excited a good deal of solicitude among cultivators that an effort should be made to arrest its progress; and I was glad to see in the valuable communication of J. W., copied into your paper the past week, from the Boston Courier, the desire of the writer, "that a course of experiments through the whole progress and transmutations of this destroyer during the year" should be made.—To aid this desirable object, I have thought it might be useful to those engaged in this pursuit, to be made acquainted with the latest method adopted in Europe for the same purpose, and which I presume is not generally known here.

In a late work on "*Insects Injurious to Gardeners and Farmers*" by Vincent Kollar, Curator to the Royal Cabinet of Natural History at Vienna, and translated during the present year, by the Misses Lonsdale of England, I find an account of the *Winter Moth* and its ravages, which I presume from the description as well as from the plates accompanying the work, there can be no doubt, is identical with the canker worm moth of this country.

After treating of the habits and ravages of this insect, and the natural causes of its diminution, which are often so effectual that fruit trees remain uninjured by it for several years, the author says:

"The means of diminishing this insect, existing in nature, are, however, not equally effective every year; so that sometimes the numbers of the caterpillar increase to such a degree that the produce and vigor of our fruit trees would be alike destroyed if we did not take measures against them. We can, at least, prevent the females of the winter moth from reaching the top of the tree and laying their eggs there. We know that they have no wings, and consequently can only crawl up the trees; therefore, if we can place any contrivance round the trunk of a tree, over which they cannot pass, that tree is secure from them. No eggs can be laid there, and consequently no caterpillars will be found there in spring. Everything has been tried to keep off the female winter-moths from the fruit trees: the stems have been surrounded with tow, cotton, fir-twigs, ears of corn, and substances having a disagreeable smell; but they have passed all these barriers and reached the tops. They have been even known to pass worsted threads prepared with mercurial ointment and wound round the trees, as many amateurs of gardens have experienced. The stem of the fruit tree has also been surrounded with strong paper, fastened with pack-thread, and smeared with tar, or cartgrease. This was so far effectual that the moth stuck in the tar. But as this substance either loses its stickiness by the rain or dries quickly up, the smearing must be repeated daily to render it effectual; and this would be both tedious and expensive. If the tar be too thickly laid on, it flows from the paper on to the stem and injures the bark. Therefore those persons give us very bad advice who say that the stem itself of the tree ought to be smeared with tar, to prevent insects from reaching the top. The tar even penetrates through the bark into the wood, and destroys the sap vessels, by which young trees

are greatly injured. At last a plan was thought of, of surrounding the base of the stem with a wooden frame, or box, and daubing it on the outside with tar to avoid the bad effects mentioned above. This contrivance completely answers the end in view, as has been fully proved. The frame consists of four boards about a foot high, and rather longer than the diameter of the tree they are to surround. These four boards are to be nailed together in the form of a square open box; but the fourth board is not to be fastened on till the frame is placed round the tree, as the stem must be entirely enclosed by the boards. To prevent the sun or rain from having any effect on the tar or cartgrease, the top of the frame is to be surrounded with a moulding; that is, a thin piece of wood three or four inches broad is to be nailed on the top, so as to form a projection on the outside, and under this an angle. This angle, formed on the outside only, is to be thickly smeared with tar. This frame may thus be called a boot, as the stem of the fruit tree stands as if in a boot. It must be set an inch deep in the earth, which must be well trodden in round it, so that the moths may not get under it and reach the tree. I must here observe that the boot ought not to be made too large; but should be so fixed as to allow of but little space between it and the stem; that we may be the more certain that no pupae of the winter moth lie within the boot. But this is not much to be apprehended; for I have known of only two instances of the winter moth coming out of the earth within the boot, and consequently very near the trunk.

"At the end of October it is time to bring this wooden boot into use, to guard the stem; and, consequently, the tops of the fruit trees from the female moth. It must be smeared, as we have before said, in the angle under the coping with tar. If it is new, it must be smeared two or three days in succession, as at first the tar penetrates greatly into the wood, and soon dries. Afterwards, smearing is only necessary two or three times during autumn; and if the ground becomes frozen or covered with snow, it may be left off entirely. In spring, when the earth is thawed, the boot must again be daubed with tar, as some of the moths still come out of the earth, and once more in the beginning of May, in order that neither looper nor other caterpillars may come from other quarters, and reach the top of the tree; for the larvae are as incapable of passing the tar as the wingless moths.

"A boot of this sort is not very expensive, as it is not necessary to have the boards planed, and if not removed from the tree, it lasts several years; so that the expense for one tree amounts at most to about a penny a year. If the tar is reckoned at another penny, the whole preservative throughout the year costs only two pence for each tree. This trifling expense should not be grudged when we consider the damage which the green caterpillar does to fruit trees. Besides, by this contrivance the orchard is protected for several years from these destructive caterpillars; for if they are once nearly extirpated, it is a long time before they again increase so much as to be very injurious."

The apparent advantages of the *boot* are,

1. That the tar may be used without coming in contact with the tree.
2. The projecting moulding round the box obstructs the influence of the sun and the rain upon the tar, and consequently, it is kept much longer

in an emollient state, so that its application three times in the autumn, and twice in the spring is said to be sufficient.

3. The economy of the remedy, costing in Germany but *two pence* (four cents) per tree. In this country it would doubtless cost something more.

4. It is within the means of every one to apply it, it being only necessary to be provided with a small quantity of cheap lumber, and should the leisure time to be found in the winter season be employed to construct the boxes, they would cost but little.

In this country, the application, to be entirely effectual, should be made by the first of October, as the insects sometimes ascend the trees during that month, consequently it would be improper to defer it, as directed by Kollar, to a later period.

ELIJAH VOSE.

Dorchester, June 15, 1840.

DOMESTIC ECONOMY.

Rich Bread Pudding.—Cut a pound loaf of good bread into thin slices. Spread them with butter as for eating. Lay them in a pudding dish—sprinkle between each layer of bread, seeded raisins, and citron cut in small pieces or straws. Beat eight eggs with four tablespoonfuls of rolled sugar, mix them with three pints of milk and half of a grated nutmeg. Turn the whole on the bread in the pan, and let it remain till the bread has taken up full half the milk; then bake about three quarters of an hour.

In making boiled puddings it is essential that there should be water enough to keep the pudding covered, and that it should not be allowed to stop boiling from the commencement to the close. Water may be kept boiling in a tea kettle to pour in, as that in the pot boils away. An old plate at the bottom of the pot will prevent the pudding from sticking, and when it is done, if the bag is dipped in cold water, it will come out of the bag easier.

Rich Baked Indian Pudding.—Boil a quart of milk, and add a pint of fine Indian meal. Stir it well. Mix three tablespoonfuls of wheat flour with a pint of milk, so as to have it free from lumps. Mix this with the Indian meal, and stir the whole well together. When the whole is moderately warm, stir in three eggs well beat, with three spoonfuls of sugar. Add two teaspoonfuls of salt, two of ground cinnamon or grated nutmegs, and two tablespoonfuls of melted butter. When the pudding has baked five or six minutes, stir in a half a pound of raisins; and add half a pint of milk for them, as they will render it too dry.

Indian Boiled Pudding.—Make a stiff batter by stirring Indian meal into a quart of boiling milk or water. Then stir in two tablespoonfuls of flour, three of sugar, half a spoonful of ginger, or two teaspoonfuls of cinnamon, and two teaspoonfuls of salt. If any thing extra is required, add two or three eggs well beaten, but they can be dispensed with, and some add a little chopped suet. Such puddings require a long boiling. They will be good in three or four hours, but better for being boiled five or six, and some give a boiling of eight or nine. They require good sauce at eating.

It is a fact universally noticed, that the apple trees all over the country, were never known to be in such full bloom. Every limb is loaded with the fragrant pioneer of an abundant crop.—*Providence Journal.*

For the New England Farmer.

THE DESTRUCTION OF BIRDS.

MR. EDITOR—You stated sometime ago in your paper, that you believed the only efficient remedy against the canker-worm was the encouragement of the birds. Several means are now used to secure fruit trees against the ravages of this destructive insect, at considerable expense, most if not all of which are not fully successful. The numerous insects that prey upon fruit trees and garden and field vegetables, are the proper food of small birds. It is, therefore, reasonable to suppose that if the birds be left to increase undisturbed, they will be able in a few years completely to protect vegetation. At least, a few cheap remedies, in years particularly favorable for the growth of insects, will be sufficient. What has always been our conduct towards those useful creatures that Providence has designed for the especial benefit of man? We have allowed our boys to hunt them whenever a leisure hour occurred, and to rob their nests whenever they came across them. To destroy them has always been a favorite amusement with worthless, vicious, and idle men. The editor of the Mercantile Journal remarked not long since, that he could go as far to kick a fellow who might be seen with a gun on his shoulder traversing the fields in quest of birds, as John Randolph would to kick a sheep. That was an expression of honest indignation, sufficiently mild, yet it would be well if a majority of the people felt likewise. It was formerly the custom on the morning of "Election" day, for all the boys from five to twenty years of age, and some older ones, to "go a hunting,"—the large ones to shoot, and the small ones to pick up the game.—Since election has been changed from May to January, the practice has, in some places, been partly discontinued, yet at the present time, many thousand boys throughout the State, set out annually on the last Wednesday in May, armed for the destruction of birds. These will kill from ten to forty each, besides wounding many others. The orchards affording the most abundant game, are of course scoured first, and the trees lose their protectors and receive in return a good supply of shot in their branches. The marauders then betake themselves to the meadows and woodlands and shoot till they become tired of it. The best singing birds being more easily discovered, among such, consequently, the greatest havoc is made. If a person on the morning of old Election day, in a neighborhood where a hunt has been determined upon, listen at surprise to the rich music of the woodlands and the joyous notes of the orchards, where every tree has its songster, and then on the following morning mark the diminished sounds, he will find the contrast melancholy enough. We have on our statute book a law protecting from injury during a part of the year, partridges, snipes, quails, woodcocks, larks, robins and some other birds, which, except the robin, are the least useful of all our birds save for the table, and for that more useful than profitable,—the best sportsmen rarely obtaining enough during a day's hunt, to pay the wages of a common laborer. The partridge is in one respect a noxious creature,—preying during the winter on the buds of fruit trees, thus rendering them barren for the ensuing season. The robin is unfortunately fond of cherries, and some persons set their boys to shoot them, not reflecting that the trees receive more shot than the robins, that might have been frightened away at a quarter

the expense. The law was enacted for the good pleasure of the epicure. It has had a bad effect in giving permission to destroy all except those named in the statute. If a gang of boys enter a field with their guns and the owner or any other person remonstrated with them, he is told that they kill no birds that the law protects, and the lads blaze away, in the full conviction that they are doing nothing wrong. It is to be regretted that many otherwise respectable persons in the fall, indulge themselves now and then in hunting robins, which at that season flock together and afford an easy game. Of the system of things on the earth the birds constitute a part without which mankind could not in any considerable numbers subsist. If they were exterminated, a general desolation would come over the vegetable world, which the efforts of man could not stay. It is the sun and the rain, the labors of the husbandman and the labors of the birds, that bring to maturity the fruits of the earth. If the farmers consult their true interests they will find some better amusement during holidays for their boys than the destruction, oftentimes in a cruel manner, of useful creatures, and will secure the enactment of laws deterring others from the like mischief. We have laws punishing with severity the person found guilty of abusing a domestic animal, and the killing and wounding of useful birds and leaving their young to perish with hunger, should be punished in a like manner. All the birds ask is protection; their weight is so small as not to endanger the tenderest twig; they will work in the orchard, the garden and the field; their notes are soft, and they will give us music from morning till night, which has been admired by wise and good men in all ages, and which cannot be despised by any person having a claim to virtue or taste. W.

DELETERIOUS QUALITIES OF SALTPETRE LIQUOR.

Springfield, June 5, 1840.

To the Editor of the New England Farmer:

It is often said that "bought wit is best if not bought too dear;" but lest some of your subscribers should pay as dear as I have for knowledge, I beg leave to communicate the following fact for their benefit. I do not know but it may be known to some of your readers that the liquor in which saltpetre meat is boiled will kill hogs, if taken in considerable quantities; but I have communicated the fact to some to whom it was new. One of my neighbors engaged to provide a dinner for a large company on the last Fourth of July. As he had no convenient place in his own kitchen to boil a large quantity of meat, he requested the privilege of using a large boiler of ours, which is commonly used for washing. The amount boiled was about 150 pounds, consisting of bacon and beef cured with saltpetre. He removed all the grease which rose on the top and left the liquor in the boiler, which was thrown into the swill barrel and given to six hogs weighing about 150 lbs. each. The next morning I was informed that the hogs were sick. The four largest, who probably took most of the liquor, were in dreadful spasms and one died before any remedies could be used. I immediately sent for a man acquainted with diseases in animals, who asked as soon as he saw them if they had taken liquor in which saltpetre meat was boiled. He resorted to the usual methods of cure in such cases, but it was too late to save two of the largest which remained. One was a sow far advanced with

young, who would probably have recovered had it not been for her peculiar situation. The violent remedies resorted to relieved her of the spasmodic affections, but brought on an abortion of which she died. The three hogs were worth at least \$25, which was the price I paid for my knowledge.

One reason why injury does not often follow the use of such liquor as is strongly impregnated with saltpetre is, that in families the amount taken is not ordinarily enough to produce spasms, which are occasioned by a stoppage of the bowels: but I am told it is extremely dangerous to give such liquor to small pigs, even in the smallest quantity. The remedies resorted to in such diseases are, cutting open the flesh of the neck between the shoulders to the depth of more than an inch, and applying fine salt, large doses of castor oil, of gin, and thoroughwort tea, as strong as it can be made. But "an ounce of preventive is better than a pound of cure," and therefore those persons who have boarding establishments in which large quantities of saltpetre meat are used, will do well to be cautious in the use of the liquor. S. OSGOOD.

From the Albany Cultivator.

SALTPETRE IN MEAT.

Messrs Gaylord & Tucker:—In the 12th number of the last volume of the Cultivator, there appeared a communication on the use of saltpetre in curing meat; and the following reason was assigned for abandoning its use, viz: "It ought to be known that saltpetre absorbed by the meat, is nitric acid, or aqua fortis—a deadly poison, whereby our salt meat becomes unpalatable and pernicious." A sufficient answer to which is found in the fact, that one of the constituents of common salt is muriatic acid, as deadly a poison as the nitric acid of the saltpetre. And we might with as much propriety say, that the salt absorbed by the meat is muriatic acid, as to say that the saltpetre is nitric acid or aqua fortis: therefore, the objection applies with as much force and truth to the use of the one as the other.

Saltpetre is the product of a chemical union between nitric acid and potassa, (potash)—and salt is the product of a like union between muriatic acid and soda—and in these, as in all other cases of chemical combination, the substances combining not only lose their properties, but the substances produced generally possess properties entirely different—frequently the very opposite of those of either of their constituents. From which it follows, that a perfectly innocent compound may be produced by the combination of two noxious substances—or a noxious compound by the combination of two innocent substances: and it is very improper and well calculated to mislead, to designate a compound substance by the name of either of its constituents, as in the communication referred to, in which nitric acid and saltpetre are several times used as if they were but different names for the same thing.

Some persons think a small quantity of saltpetre very beneficial to their meat—others think it useless: the former need not be frightened from its use by the fear of being poisoned with aqua fortis, nor the latter deterred from trying it. J.

Cultivating the earth without well manuring it induces two great evils: it impoverishes both the husbandman and the soil.

From the Albany Cultivator.

ON THE CULTURE OF LUCERNE.

Respected Friend, Jesse Buel—I sometime since received a letter from thy father, requesting me to give him such information as I am possessed of, respecting the culture of lucerne; and thinking thou would like to have it, I have concluded to send it to thee, as I think every farmer who has land suitable for it, ought to have plenty of this valuable grass. It requires a good deep soil, that has not clay bottom. I have succeeded beyond my expectation, and now find no more difficulty in raising it than any other crop. In order to prepare the land for it, spread plenty of unfermented manure on it, and plough it in and plant corn, which ought to be well managed, allowing no weeds to grow. After the corn is taken off, give it a good deep ploughing, and let it remain in that state until spring, if it be sown with barley; but if with winter wheat, harrow it well, and collect the roots and loose stones, and should there be any fast stones they ought to be removed; then spread about forty bushels of ground bones per acre and harrow it in; but if bones are not to be obtained, any good rotten manure that has no seeds of weeds in it, will answer it. And as it is best to lay the land in ridges about 24 feet wide, open a furrow about 12 feet from the fence, and let the near horse return in it; then open another in the same manner, 24 feet from it, and so continue until the whole is finished; then sow the wheat and plough it in, not very deep, filling the furrows which were opened, and harrow it once over. As it is best to have it as smooth as may be, I made a hone with a plank about nine feet long, and two poles, pretty much the shape as those we smooth our roads with; and if it is not heavy enough lay a post or two on it. It ought to be so constructed as to draw the loose earth towards the furrows. In the spring, about the time clover seed is sown, sow about twenty pounds of lucerne seed to the acre, and harrow it in with a sharp, heavy iron-toothed harrow twice over, once each way, and roll it with a light roller, across the ridges, to be drawn by one horse. After the grain is taken off, let it remain in that state (not pastured) until spring. Soon after the frost is out of the ground, before it is much settled, harrow it once each way with the heavy harrow. I had mine pointed with steel. The harrow ought to be made in two parts and hung together with hooks and eyes; then it can readily be lifted up on one side by the driver, and cleared by a boy to accompany him with a rake. It may be harrowed three or four times over after every mowing, remembering to pick up the loose stones. The reason I recommended laying it in ridges is, because it can be more readily smoothed with the hone. If it is not smoothed, the harrow will not have the desired effect; and the natural grasses are apt to get in. I generally let mine stand until in blossom, when it is designed for hay. I usually get three good crops, and think the hay is better for all kinds of stock than any I have ever seen. My first crop was sometimes been so large, that it is best to cut it rather earlier, as it will sometimes lodge and may injure the roots.

As this grass requires more time to cure than some others, I thought it might be well to inform thee how I manage it. That which is cut in the forenoon, if the sun shines, may be turned with a rake towards evening, but not opened; and that which is cut in the afternoon may remain until the next afternoon, before turning it. That which was

first turned ought to be turned the next forenoon, and put in cocks early in the afternoon, and let it remain two nights in cocks; then open it and lay the fork-falls separate, shaking it well, and if it does not appear to be sufficiently cured after being turned, put it up in cocks and let it remain one night more. When the hay is housed, I generally put half a bushel of salt to a load—say to about fifteen hundred.

As this grass, especially the first crop, is apt to be very large, it is liable to be injured by heavy rains when in cock. I would therefore recommend to those who raise it, to get a quantity of low-priced yard-wide linen cloth, and give it a thin covering with boiled tar, with a painter's brush, on both sides, and sift some fine sand on it while warm; and when dry, cut it in squares and fasten a small stone to each corner to prevent their blowing off the cocks. These cloths cost but little, and with care will last many years, and may be very useful for other kinds of hay; for want of them, one of my neighbors had a large quantity of clover hay much injured.

When the swaths are turned the second time, let two be turned towards each other, then when it is raked, the horse can walk between them, and let a boy keep by the side of the horse, and when the rake is full, let him open the swaths with a fork, that the rake may readily enter.

I have been thus particular, being desirous that whoever may wish to raise this grass, may succeed, as a number of my friends have been disappointed for want of proper management.

Thy assured friend,

JAMES BYRD.

P. S. If the seed is sown on winter wheat in the spring, it ought to be done when the ground is neither too wet nor too dry, but when it will crumble.

Flushing, 2d mo., 19th, 1840.

From the Albany Cultivator.

PREPARATION OF SEED CORN.

Messrs Gaylord & Tucker—I send you the result of an experiment made in planting corn the past season. Having seen statements of the benefits derived from steeping the seed in a solution of the sulphate of iron (copperas), as securing it against the ravages of birds and cut-worms, we resolved upon giving it a trial. Mr Jacob Kirk, (with whose crop the experiment was tried), procured a few ounces, dissolved it in hot water, and poured over the corn. After remaining in the solution from six to eight hours, the corn was taken out, rolled thoroughly in plaster, and planted. A few rows of the same kind of corn was planted in the middle of the field, without steeping the seed, but just as it came from the cob. The field was likewise planted with pumpkin seeds, also without preparation. After the corn and pumpkins had come up, I observed that many of the latter were cut off by the worms, but could not see a single stalk of corn disturbed, until I examined the rows (for I had marked them) the seed of which had not been prepared. Here I found the worms at work, nearly a tenth part of which they had destroyed; the birds had likewise taken some. The steeped corn was of a greener and more healthy color than the other; grew faster, with stouter stalks, while that from the unprepared seed could readily be pointed out by its more yellow and dwindling appearance; neither was the yield so great as the other.

Now whether this difference in yield is to be attributed to the copperas or to the plaster, or to both, I have yet to learn; but think the copperas prevented the birds and worms from committing depredations, as we have frequently rolled seed corn in plaster, but have never found that a security against either birds or worms.

The above is at your service; you will please pardon errors in composition, as my province is behind the plough and not the pen.

Yours,

R. FOSTER.

Blast—A disease of plants, to which by different writers has been given the name of blight, blast, and mildew. The latter, however, is evidently a distinct disease, and produced by different causes. The blight which sometimes strikes the grain of whole districts, would seem to be owing to atmospheric causes, and governed by the course of the winds. Impoverished land, too great quantities of seed, or injudicious culture, may produce this blight, but in this country it is oftener observed as an effect of drought. Blast from fungi is the kind of blight which attacks grain also, and which has been erroneously attributed to particular plants, as the barberry bush, since the fungi on the leaves of this plant, and those that cause the blight in wheat are clearly distinct.—*Ill. Cult.*

Family Flour.—By the introduction, into some of the mills in this vicinity, of the improved machinery for the manufacture of superfine flour, we are now enabled to get that article of the very best quality, as regards the manufacture, with the additional recommendation of having it *fresh ground*. This very important difference—a difference that is generally appreciated in relation to common meal, and will be in relation to flour, when once tried—is a consideration which will recommend the flour to all those who love to have their bread of the best and most wholesome kind. We have used two sacks of it, which was prepared by Putnam King, at Clark's Mills, in Sutton, and found it decidedly better than any other flour we have tried. It is kept constantly for sale, in this town, by Francis Blake & Co., who are the agents for the manufacturers.—*Worcester Spy.*

A Good Thing—a strong cement for glass, wood, &c.—Steep isinglass twentyfour hours in common white brandy, then gently boil and keep stirring until the composition is well mixed, and a drop, if cooled, will become a strong jelly. Then strain it through a clean linen cloth into a vessel to be kept closely stopped. A gentle heat will dissolve this glue into a colorless fluid. Dishes of wood, glass, or earthen, if coated with this cement, will break elsewhere rather than separate in the old break. In applying the cement, rub the edges which are to be united, then place them together, and hold them for two minutes, and the work is done. This is very easily done, and incomparably better than any thing else for the purpose.

Vegetable Votiv—In 1643, a Ipswich, Indian beans were ordered to be used in voting. The white denoted yes, the black nay. In 1648, they were required to be sealed up and forwarded to Boston. In 1680, Indian corn was ordered to be used for this purpose, and sealed up in a paper containing the name of each candidate, and sent to Boston, on election day.

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JUNE 17, 1840.

ELEMENTS OF HORTICULTURE. By J. E. TRESCHMACH-ER. Boston: Charles E. Little & James Brown.

Having looked over this neat little volume, we can confidently recommend it to all who have any thing to do with the cultivation of the earth, whether it may be termed Floriculture, Horticulture or Agriculture. It is to be lamented that so much ignorance exists relative to the elements of horticulture. Every farmer should understand the science as well as the practice of agriculture. This little book is well calculated to give him the first lessons. We have no doubt it will be read with profit by all who are inclined to receive instruction. We are well acquainted with the author, and consider him as well qualified to impart instruction on the subject as any other person in the county. J. B.

THE ROSE-BUSH SLAG.

We would direct our readers to the proceedings of the Massachusetts Horticultural Society on Saturday last, which are subjoined, in which an additional premium of *One Hundred Dollars* is offered for the most effectual mode of destroying the Rose Bush Slag. To the forest this insect has been a great annoyance, in some sections of the country utterly blasting the efforts of the cultivator; causing him to give up in despair the cultivation of the rose. The gentleman who offers the fifty dollars in connexion with the other fifty proposed by the Horticultural Society, has had his hopes repeatedly disappointed by this noxious insect, and considered the premium offered heretofore, not in proportion to the magnitude of the evil. He has, therefore, come forward in this liberal manner, hoping that with the amount already offered, it would be a sufficient inducement to stimulate our gardeners and others to find the desired remedy. The floral community must feel themselves under great obligation to the gentleman who first made an offer, and opened the way for the more munificent premium; he will be remembered with gratitude by the members of the Society for this and repeated instances of his generosity and public spirit.

We would take the liberty now while our hand is in, to remind those who have an abundance of means and wish to benefit the community that there are a variety of insects which defeat the labors of the husbandman as well as the florist, and which would prove a great blessing to the country to be rid of. There is the canker worm, the wheat fly, and a long list of voracious vermin, for the most effectual method of exterminating which, large and generous premiums ought to be offered. Now who will have the honor of offering something handsome to the person who shall discover a remedy against the destructive ravages of the canker worm? J. B.

At a stated meeting of the Massachusetts Horticultural Society, held June 6, 1840, communications were received from Messrs Walker and Haggerston, on the subject of increasing the premium for the most successful method of destroying the slug which infests the rose bush, whereupon it was voted that said communications be referred to a committee consisting of Messrs Walker, Haggerston and Aspinwall, to report thereon in one week.

REPORT.

The committee to whom was referred the communication of Mr Haggerston, offering fifty dollars (provided

the Massachusetts Horticultural Society would add the same amount) as a premium for the destruction of the rose slug, beg leave to report that they have attended to that duty. The committee recommend that the Society accept the proposal of Mr Haggerston and offer a premium of one hundred dollars, in addition to the sum of twenty dollars already offered by the Society, for the effectual destruction of said slug; the premium to be paid whenever satisfactory evidence shall be given to the Society of a plan to destroy or to prevent the ravages of the slug, without injury to the bush or its foliage. Per order, S. WALKER, *Chairman*.

Boston, June 13th, 1840.

At an adjourned meeting of the Massachusetts Horticultural Society held Saturday, June 13, 1840, it was voted to accept the above report.

Attest, E. M. RICHARDS, *Rec. Sec'y*.

The following are the communications alluded to:

ROXBURY, June 3d, 1840.

SIR—I have the honor to transmit the enclosed communication, addressed to me from Mr David Haggerston, of Watertown.

The slug, that has for several years past destroyed the foliage of the rose bush, is well known to every practical florist in this section of the country; its destruction by various means has been attempted, but as yet without success.

The additional premium now proposed, if it should receive the sanction of the Massachusetts Horticultural Society, will give a fresh impetus to the exertions of those who have so far labored in vain to destroy this eye sore, the rose slug; and will probably call into the field an army of Flora's living subjects, who will not, I trust, lay down their arms until they shall have annihilated the foul defacer of the mantle of the "queen of flowers." I am, sir, with great respect,

Your obt^d serv^t,

S. WALKER,

*Chairman Com. on Flowers.*HON. E. VOSE, *President Mass. Hort. Soc.*

WATERTOWN, May 26th, 1840.

MY DEAR SIR: In conversation with a gentleman since I saw you, I mentioned to him the intention of the Horticultural Society of offering a premium for the destruction of the worm or insect that infests the rose bush and destroys the foliage: he was much pleased and commended the society for their efforts to accomplish so desirable an object; but when I mentioned the sum intended to be given, *ten Dollars*, his idea was precisely mine, that it would result in no good. For the last five or six years he has seen experiments tried and every thing done that could be thought of, for the destruction of the above insect without the least success. His idea is that the premium ought not to be less than *one hundred dollars*, and he wished me to say to the society that I could procure fifty dollars for the purpose, provided the society would make it up to one hundred. As it is not at all likely that I shall be at the next meeting, I take the liberty of troubling you, knowing well how much you are interested. If you will have the goodness to make the proposal to the society, you will much oblige

Yours, very truly,

DAVID HAGGERSTON.

S. WALKER, Esq

Massachusetts Horticultural Society.

EXHIBITION OF FLOWERS.

Saturday, June 13th, 1840

Bouquets, by Messrs Carter, Howe, William Kenrick, Jno. A. Kenrick, Hovey, Winslip, Breck, Meller, and Walker.

Native flowers, by H. M. Par^r.

Paeonies, by Wm. Kenrick, Jno. A. Kenrick, It. Howe, S. R. Johnson, Winslip, Breck, Carter, and Walker.

Roses, by S. R. Johnson, Winslip, Howe, J. A. Kenrick, Wm. Kenrick, Carter and Walker.

Fine specimens Dwarf Rocket Larkspur; Neapolitan do., and Sweet Williams, from Joseph Breck & Co.

By Wm. Kenrick, Newton; Paeonies, Whiteley, P. Humei, P. fragrans, &c; Iris, various kinds; Dianthus, var. Tradescantia, var. blue and white; Chinese double blue Larkspur, (splendid); Honey suckles,—Yellow Trumpet, Orange colored or Pubescent, and other varieties; Spike double white, Spiræa oppositifolia allium; Hemerocallis flava, or Yellow Day Lily; Canterbury bells; Ring-leaved Willow; Purple Beech; Carolina large flowering Syringa; Laburnum Alpinus, or Golden Chain, Scotch var; Roses, Scotch and other varieties; Harrison's Double Yellow Rose, Red Moss, &c.; Magnolia tripetala or Umbrella tree.

By John A. Kenrick, Newton; thirty var. Roses; Paeonies, var. Humei, fragrans, Whiteley; Hemerocallis lutea; Lythrum, &c.

Native plants, by T. Lee, Esq.; Kalmia latifolia; do. angustifolia; Magnolia glauca; Rhoixia Virginica; Orchis hephtaglottis; Sabbatia chlorodes.

From Hovey & Co.; Echinoacetia caryeii; Cereus speciosissima; Epiphyllum Ackermanii. Dahlia; Double Dwarf Rocket Larkspurs; seeds sown in October, came up 10th of April 1840; first flowers open June 2d.

Messrs Haggerston and Breck were appointed judges on the Paeony. They awarded the first premium of \$5 to Wm. Kenrick, and the second premium of \$3, to Jno. A. Kenrick.

For the Committee.

S. WALKER, *Chairman*.

EXHIBITION OF FRUITS.

Strawberries; Methven Castle, Monthly, and Seedling, from J. L. L. F. Warren.

Seedling do., two varieties, from Hovey & Co.

Early Virginia do., from Mr Vose.

The seedlings from Hovey & Co. and Mr Warren were very large and splendid specimens.

For the Committee,

L. P. GROSVENOR.

EXHIBITION OF VEGETABLES.

By James L. L. F. Warren, Brighton; fine specimen of the Sontigate Cucumber; also on the two Saturdays previous fine specimens of the same.

For the Committee,

RUFUS HOWE.

NOTICE. The premiums on Roses and Pinks will be awarded on Saturday next, 20th inst.

Per order,

S. WALKER,

Chairman Com. on Flowers.

Boston, 13th June, 1840.

☞ We would invite the attention of our readers to a communication on our third page, from the Hon. Elijah Vose, on the Canker worm.

Mr Foster's communication is postponed until next week for want of room.

☞ The nature of lime ought to be understood before it is applied for manure; as that contaminated by magnesia is injurious to the growth of vegetables.

BRIGHTON MARKET.—MONDAY, JUNE 15, 1840

Reported for the New England Farmer.

At Market 325 Beef Cattle, (including 50 unsold last week) 18 pairs Working Oxen, 30 Cows and Calves, 450 Sheep and 650 Swine
50 Beef Cattle and 20 Sheep unsold.

Prices.—Beef Cattle—We continue to reduce our quotations to correspond with sales. Extra \$6 50. First quality, \$6 00 a \$6 25. Second quality, \$5 75 a \$6 00. Third quality, \$5 50 a \$5 75

Working Oxen—We notice a few sales. \$70, \$82, \$90, \$95, and \$115.

Cows and Calves—Sales \$20, \$24, \$25, \$50, \$32, \$37, and \$38.

Sheep—Lots at \$2 25, \$2 50, and \$2 75. Wethers \$2 75, \$3 00, \$3 12 1/2.

Swine—“Dull.” One entire lot large hogs 4 for sows and 5 for barrows. Selected lots J 1-2 and 5 1-2. Small pigs 5 1-2 and G 1-2. At retail from 4 1-2 to 5 1-2.

THERMOMETRICAL.

Reports for the New England Farmer.

Range of the Thermometer at the Garden of the propagators of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure. week ending June 14.

WANTED

To hire for a term of years and at a moderate rent, a Farm of 15 to 30 acres arable land in good condition, with a good barn and water for cattle and privilege of cutting fuel.

The distance from Boston not material. Apply at this office.

June 17. 11

SUPERB ROCKET LARKSPUR SEED.

The subscribers offer for sale a quantity of Superb Double Rocket Larkspur Seed, of their own raising saved from double flowering plants only, embracing all the different colors For fine, strong and early plants, the seed should be sown in August.

JOSEPH BRECK & CO.

SCYTHES, RAKES, &c.

The subscribers offer for sale a very extensive and complete assortment of Scythes, Rakes, &c. consisting in part of 300 dozen Phillips' Messer and Colby's superior Scythes.

- 50 " Metcalf's do do.
- 50 " Tall's cast steel do do.
- 25 " English do do.
- 10 " do do do.
- 10 " do do do.
- 100 " Hall's Rakes, superior.
- 100 " Wilder & Eddy's do do.
- 200 " Common do do.
- 100 " Clapp's patent Scythe Smiths.
- 50 " Baker's do do do.
- 100 " Common do do do.
- 2500 " Austin's superior Rifles.
- 2000 " Common do.
- 1000 " Scythe Stones.
- 100 " Grain Cradles superior.

They would respectfully call the attention of Dealers and Agriculturists to the above assortment, which consists of many of the best kinds now in use, and which they are prepared to sell at the very lowest prices.

JOSEPH BRECK & CO.

New England Agricultural Warehouse and Seed Store, 51 & 53 North Market Street.

May 20.

GOLD FISHES AND CANARY BIRDS.

For sale by JOSEPH BRECK & CO. 52 North Market Street.

April 29.

FIR TREES.

Now is the best time for transplanting Fir Trees. Orders for any variety or size will be promptly attended to.

May 6.

JOSEPH BRECK & CO.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and horse, with a boy to lead, will rake on an average from 25 to 30 acres per day, with ease, and do the work well. They are coming into very general use in all parts of the country, and will, no doubt, in a few years, supersede the use of the common hand rake. There is a great advantage in this rake over all others, as the person using it does not have to stop the horse to unload the rake.

GRAIN CRADLES.

The Grain Cradle is an article which is coming into very general use in the New England States, where they were till of late but little known, although they have been in very general use in the southern and western States, for many years, and which is found to be decidedly the best mode of harvesting grain, as it is supposed one man will cradle five acres in a day when he cannot reap more than one. The difference in gathering a crop is so much in favor of cradling, that we must suppose that it will be the only mode adopted hereafter and the grain cradle will become of as much use, as an implement of husbandry, as the plough now is.

There has been a very great improvement in the manufacturing of this article, they are now made on the most improved plan; the scythe is well secured and finished in a superior manner and made of the best cast steel.

CARNATION SEED.

The Subscribers have received from Rotterdam, a small quantity of extra fine Carnation Seed, saved from one hundred choice varieties, which they offer at 25 cents per paper. We have tried it, and find that it vegetates freely. It cost us 30 guilders per covey, and from the representation made, no doubt will give satisfaction to those who may be disposed to try it. We have also very fine carnation seed at 12 1/2 cents per paper. The seed may be sown with good success any time in May or June.

JOSEPH BRECK & CO

FOR SALE.

For sale a fine heifer Calf, from one of the best cows in the country, and by the celebrated Ayshire bull imported by Mr Cushing. Inquire at this office, or at Washburn's establishment at Brighton.

May 20.

HORTICULTURAL TOOL CHESTS.

Containing a complete set of Garden tools of superior finish and style, recently received from Liverpool and for sale at the New England Agricultural Warehouse and Seed Store.

JOSEPH BRECK & CO.

GARDENERS KNIVES.

JOSEPH BRECK & CO. have this season imported and now offer for sale a few very superior Garden Knives, for pruning, &c. manufactured expressly for Gardeners, and warranted superior to any article of the kind here imported.

Also—a large assortment of Budding Knives, Grape Scissors, &c. &c.

Northern pulled.

(Continued from page 414.)

As my readers may not be acquainted with the fare of travellers in the west, I shall be more particular with regard to our accommodations at this place, though I admit that I take an extreme case; but still a pretty good general notion may be gathered from it. Brodie's grove contains from 100 to 200 acres, and there are three families living there whose nearest neighbor is seven miles off, and the nearest mill and grocery is at Belvidere, 23 miles, and in this particular they are better off than many others in the country by nearly a day's ride. For our horses we could obtain neither hay nor grain, but the young men went out into a sough near by, and mowed some coarse grass, which sufficed for our beasts; for ourselves we obtained some new corn bread in the shape of a good thick johnnycake with butter, and a bowl of milk, which we ate, seated on a good oaken bench, it being out of the latitude for chairs, and while thus employed, a half grown chicken happened in at the open window and laid claim to a share of the butter. Our supper over, we lighted our pipes and began to take a close survey of the premises. The house, or cabin rather, was of the ordinary construction, being about 20 feet square, built of logs locked together at the corners, a door of goodly dimensions in the middle of one side, and a window exactly opposite upon the other side, with a huge fireplace at one end, and at one corner a rude ladder which served as an apology for a staircase leading to the attic story. The cabin had been "chinked and dabled"—that is, the cracks between the logs had been filled with bits of wood and plastered over with clay, but this finish had yielded to the weather, in many places affording very convenient peeping holes, and giving good assurance that the interior was well ventilated at least, and to complete the elegance of the mansion, it was enclosed, according to the fashion of the country, with a worm fence, to keep the hogs and cattle at a respectful distance.

We observed three or four athletic, savage looking fellows, well armed with pistols, who had apparently no business, but were lounging about, amusing themselves with violins, and who were very inquisitive, with regard to our route and business, and as they seemed to fancy my friend's horse, he was not a little uneasy lest the said horse might be found absent in the morning. We took care, however, to show no concern, and kept our suspicions to ourselves. Having carefully noticed the whereabouts of this den of horse thieves, which in fact it was, we retired early, and ascending the ladder aforesaid, we took possession of a sort of flock-bed upon the floor near a good sized crevice, through which we could, by the light of the moon, observe all that passed without. Not long after the loafers came up and occupied other beds similar to our own, and about midnight another came from abroad, but finding all full he went away probably to another cabin. Notwithstanding all these circumstances, I was so fatigued with my journey that I could not withstand the attacks of Morpheus, and slept soundly until near sunrise, when we arose and found our horses standing quietly at the fence where we had tied them, and hastily putting on their saddles we left and went on our way, grateful that we were still in life and had horses to ride.

I may as well state here that this part of the country is much infested with horse-thieves and

counterfeits, who are supposed to have a line of stations from Wisconsin through Grand prairie and into Missouri; and Driscoll's and Brodie's groves are suspected to be two of the principal posts, and never was a country better adapted to such a business than this, these insulated groves separated by smooth open prairie, where a pursuer may be seen at a great distance, giving the rascals ample time to make all snug and to conceal themselves and their plunder by day and to escape by easy stages at night.

We breakfasted late at Driscoll's grove, then pursuing our journey, four miles brought us to the south branch of the Kishwaukee. This is a rapid and very clear stream. From thence to Belvidere on the north branch is twelve miles, most of the way over high rolling prairie. From the top of a hill four miles from town is one of the finest prospects in the country. We observed two men following us on the prairie, whom we lost sight of as we descended the hill south of Belvidere. Instead of going into the village we turned to the right and went two and a half miles up the river to my friend's house;—the next morning we learned that two saddles had been stolen in the village, very probably by the fellows that followed us: but our horses were safe in my friend's stable.

Belvidere, the seat of Boone county, is prettily situated on the edge of Squaw prairie, which was an old Indian settlement, on the north branch of the Kishwaukee or Sycamore river. At present the village is not large but it is gaining fast, being in one of the finest sections of country in the west, and on the State road from Chicago to Galena, it bids fair to become an important town. It has a small church, an academy handsomely situated on a mound near the centre of the village, two public houses, several stores, two sawmills, and a flour mill. On the mound the skeleton of *Big Thunder*, a celebrated Indian chief, is still to be seen in a sitting posture, within a small stockade erected by the natives.

The country about the Kishwaukee is chiefly oak openings or barrens, though there is no lack of prairie of the best kind, and immediately on the river there is considerable meadow or bottom land, too low for cultivation, but the soil is firm and very well adapted for grass, and the settlers depend upon these bottoms for all their hay. The Piskasaw, a beautiful stream from the north, enters the Kishwaukee one and a half mile east from Belvidere. The water of these streams is clear and sparkling, the current quick, and the beds hard gravel and pebbles. The water of the wells in this section is clear and pleasant, and free from all impurities except lime, with which all the water in the whole western country is impregnated. I stopped in this neighborhood about a fortnight, making observations and collecting information about the country, the substance of which I shall give in another place.

(To be continued.)

A Tale of Horror.—The New Orleans Times publishes the following horrible tale, on the authority of a friend just arrived in that city from Illinois: "On the 17th ult., two gentlemen, both strangers in the West, had some dispute about the occupation of the back seat in a coach which runs between Peru and Chicago. Each drew a pistol at the same instant—each fired, and both fell to rise no more; for the contents of the loaded pistols had the effect they intended to have; the contents of one entering the body just below the heart—those of the

other passing through the head of the opponent.—The driver, in haste, stayed the progress of his steeds to ascertain the cause of the reports of pistols, and, unloosing the coach doors, what a horrible scene did his eyes behold! Two men, who but a few hours before, left the hotel at Peru, in social mirth and glee, now weltering in their blood!—They were the only passengers, and both died before any aid could be called, the distance from any house being some miles. The names of the unfortunate individuals are supposed to be, from papers found about them, R. L. Winn and Jos. D. Brown. The former had about \$900 in his possession—the latter, \$450—mostly in Northern funds."

The Wheat Fields.—We are happy to learn from all parts of the State, that the wheat fields never looked so well and promising in Michigan as they now do. The cold wet weather has had a most favorable effect upon them. It is supposed there is one fourth more wheat in the ground this year than last.—*Troit Free Press.*

SIAA SILK WORMS EGGS—\$5 PER OUNCE.

The Eggs of the celebrated Siasa Silk Worm, now offered for sale, were raised in 1839 by M. Camille Beauvais, superintendent of the experimental silk farm, established near Paris, by the government of France. The Siasa Silk Worm was introduced to France from China by Louis XVI. in 1784, and has been proved by M. Beauvais to be superior to all other silk worms. They are also stated to possess the precious property of hatching simultaneously. Just received, by the subscriber, from the Chevalier Bodin, who is the only agent for their sale in France.

Each sheet contains an ounce and is signed "Camille Beauvais."
WILLIAM KENRICK, Newton.
Or apply to JOSEPH BRECK & CO.

WANDERINGS IN THE WEST IN 1839.

No. V.

(Continued from page 420.)

In company with a gentleman from Massachusetts who arrived a day or two after I did, by a different route, I made an excursion into Wisconsin. Leaving Belvidere we followed the Galena road to Beaver creek, then turning north we rode through a fine country of alternate barrens and prairie, affording many very beautiful prospects, to Beloit, at the mouth of the Turtle river which enters Rock river exactly on the line of the state and territory. Here is a thriving little town, having several mills in active operation, 22 miles from Belvidere: thence we passed up on the east side of Rock river six miles and stopped for the night: it was near the middle of July and the weather very warm, and the heat and the mosquitoes, which were of the "tallest kind," caused us a rather uncomfortable night.

Early in the morning we started and following the river, at the end of a mile came to the bed of an ancient river, about the present size of Rock river, tending to the eastward. Crossing this, our route was over high prairie, which is uniformly about four to six miles wide, and at that distance from the river the land appears to rise and is covered with wood. After riding six miles the road leads into a ravine, where we missed our way and followed another road up the ravine a short distance, when we found that it turned eastward, where it presented the perfect outlines of an ancient river-bed: there were bluffs upon each side and numerous gulleys worn out by the water, and its course curved towards the south and no doubt is a part of the same that we saw below, and from all appearances it is probable that at some time the Rock river meeting with obstructions at the sugar loaf mountain, which is just below, made a circuit to the eastward, something in the form of an oxbow, and came into its present course about five miles below. Finding that we were wrong, we turned back and with some difficulty found our way to Janesville, a paltry little town with only one good house. We there forded the river, the water being about five feet deep and wetting our saddles; we then followed the road on the west side of the river towards Madison, whither we intended to go. There is a belt of timber, chiefly burr oak barrens, next to the river, then there is a strip of prairie about five miles wide and parallel to the river, and on the west the prairie is bounded by a grove of timber. These features continue nine or ten miles to the junction of the River of the Lakes: there are no inhabitants and the travel is not sufficient to kill the grass, excepting a narrow path resembling an Indian trail. We had been directed at Janesville to keep the plainest track, and when we came near the River of the Lakes it turned to the left more than we thought it ought, but we saw no other track, and therefore followed it. Before we had travelled far, the track turned more to the left and out of the course for Madison, until we found our-

selves travelling S. W. We were certain that we were going wrong, but there was no person within ten miles of whom we could enquire the way, so we concluded to follow the track lead where it might: as our only business was to see the country, it was little matter where we went. Our route led through a pleasant district of prairie and timber until we came to Sugar river, where we met a traveller with a horse and wagon, of whom we inquired where we were and whither the road led. He informed us that we were upon the public square of the town of Centreville, 35 miles from Janesville and on the road to Mexico. In travelling this distance we had seen no person nor found any water: our traveller informed us of a spring at Sugar creek, a smaller stream four miles further, and that three or four miles beyond that we would find inhabitants.

Centreville was laid down upon our map as a large town having several roads leading from it in different directions, but in fact the town exists only upon paper, not a tree having been cut, nor any trace of civilized man being seen, and the only road was the indistinct trail which we had been following. We forded the river, here about three feet deep, and rode on to the creek where we found the spring which the traveller had described, and about sunset we brought up at the hospitable cabin of an old Pennsylvanian, where we were kindly entertained after a ride of about 45 miles, without refreshment of any kind except water.

Our host had a farm of about 800 acres, which he had lived upon one season only, and had not cultivated a large portion of it, but he had a strong force and was making preparations for producing on a large scale; the family was intelligent and I noticed a good many books and papers which it is not very common to see in a new settler's cabin.

It was late in the morning when we left them: we were now farther from Madison than we were the morning before, and we had lamed one of our horses badly, and therefore we gave up our purpose of going thence, and determined to make a circuit by the Pekatonica homewards. Accordingly we rode two or three miles westward to Richland grove, a fine body of timber land about twelve miles by five in extent, and then struck across the prairie about six miles to Rock grove, where we came into the road leading to Rockford. Passing by this grove we saw a great plenty of fine raspberries, the only berries of any kind that I had seen in the country.

From Rock grove the road runs eastward through a very good tract of country near the boundary of the state and territory. We rode slowly until nearly night when we stopped in a settlement of Vermont people, a number of families of whom had removed together from the same neighborhood and settled here in one of the best farming districts in the country. We had now travelled through Rock and Green counties in Wisconsin and entered Winnebago county in Illinois. As our entertainment was not the most agreeable, we got off early in the morning, and a ride of four miles brought us to Trask's ferry, where we crossed the Pekatonica.

This river is a deep muddy stream, and runs through a wide bottom covered with very heavy timber.— From thence to Rockford, 12 miles, our road was over dry rolling prairie without inhabitants, except at a small grove four miles from town: in our ride we met a number of wagons with emigrants from Canada. Rockford is a tolerably pleasant town of 40 or 50 houses on both sides of Rock river, and is the seat of Winnebago county. There is a ferry and a landing place having a smooth rock bottom, with about two or three feet of water; this rock constitutes the principal obstruction to the navigation of the river, and from this the town derives its present name: it was first called Midway, on account of its being half way between Chicago and Galena. Above Rockford the river is navigable about 70 miles. We crossed the river and dined at the Rockford house, a hotel of considerable pretension; but I never fared poorer at any hotel in my life, nor paid a more extravagant bill; and I would advise travellers to stop at the public house on the other side of the river, where I dare say they will be better served.

The environs of Rockford are very beautiful: the land is gently undulating, the prairie and wood alternating agreeably, and a large portion of the land is fenced and dotted with farm houses: indeed the remark justly applies to the whole country bordering on Rock river: a more beautiful country cannot be imagined. After dinner we again mounted our horses and reached home toward night, having travelled in this excursion about 140 miles.

During the remainder of my stay at Belvidere I spent my time riding about the country, and made acquaintance with a number of people with whom I was pleased so much that I concluded to settle here if anywhere in the west, and purchased a beautiful situation in the neighborhood; but the western fever had been somewhat checked, and I had some misgivings with regard to removing, and resolved to return home and reflect upon the subject, with the assistance of the new light that I had acquired in the course of my travel; and now if my readers will accompany me back to New England, I will endeavor to entertain them on the way and then give them the reasons that have determined me, and which I think will be useful to them in their determinations upon the same question.

My friend accompanied me to Chicago, whither we rode in a wagon. The country eastward as far as Pleasant grove is very fine and fast filling up: from thence to Fox river there are few inhabitants, and the country is not so pleasant being chiefly dry rolling barrens.

Elgin on Fox river appears to be a growing town, and is rather pleasantly situated. The river is broad but too shallow to admit of navigation. We rode 12 miles from Elgin that day in a bitter N. E. wind, so cold that we were uncomfortable with cloaks on, and when we stopped for the night, I was quite chilled, and was glad to occupy a seat by a good fire the whole evening.

Early in the morning we resumed our journey and arrived at Chicago about noon. Chicago is situated at the mouth of a small river or creek, and

is surrounded by a low flat prairie which extends either way about 10 miles, and in wet seasons the roads in the vicinity are almost impassable: the site of the town is not more than 18 inches above the level of the lake: the location is favorable for business, and the canal which is now being made hence to Peru, connecting the lakes with Illinois river, will give the town great advantages.

There are some very good buildings in Chicago, particularly the "Lake House," one of the finest hotels in the country; but on the whole the town does not make a good appearance. The population cannot be more than 5000, though it is often stated much higher. The next morning after my arrival I took passage on board the steamer Gen. Wayne for Buffalo, and at 10 o'clock I took leave of Chicago.

It would be impossible to describe the loneliness that I felt when the boat was about leaving the wharf: I was upon deck casting a last look upon the town, and my attention was arrested by the crowd, most of whom seemed to be saluting and exchanging good wishes with friends on board, but not one of the hundreds that were there were known to me,—not one was there to bid me God-speed: I felt that I was a stranger, and far, far off were all who could feel any interest for my welfare.

Upon going into the cabin I found that most of the passengers were Yankees, and I recognised one who travelled through Pennsylvania with me on my way out: we were soon acquainted and I found the society on board much more agreeable than is usual with the promiscuous collections on board steamboats.

(Continued on page 428.)

For the New England Farmer.

FATAL DISEASE IN CALVES.

MR EDITOR.—A farmer in North Andover selected from ten calves, three for breed, a bull and two heifers—two born in March, the other in April.— They grew finely, and were in form and size a more perfect specimen of kind than is usually to be found. Their principal food was skimmed milk. They were kept in a large pen in the barn until about two weeks before their death, when they were put into the enclosure about the dwelling house. On Monday evening last they ate but about half their usual quantity of milk, but as they appeared in perfect health, no notice was taken of it. On Tuesday morning the bull was found dead: on Wednesday morning the other two went to the cellar door, which opened on the outside of the house, where their milk was preparing, and both appeared impatient to get to it; and when the person was about to give it them, one turned its head aside and commenced running round furiously in a circle, bellowing as if in great distress. It was shortly seized and with great difficulty held by two men, and in fifteen or twenty minutes it fell and expired. The sweat in the mean time on the skin became a perfect foam—it was literally in its grave. A post mortem examination was held in all its parts, and not the slightest appearance of poison or disease could be discovered in the entrails or head, unless the entrails had an uncommon degree of warmth. The remaining calf being removed to the barn was copiously bled in the neck, and during the day shew no particular signs of disease: at evening it took but about half the quantity of milk offered to it, its usual allowance: at midnight a distressing bellowing was heard: the men repaired to the barn

and found the calf running in a circle in the stable, exhibiting all the symptoms of the last dead: in about half an hour it fell, and uttering two or three bellows, expired.

This case was more aggravating, as the calves, for their superiority as perfect and well grown animals, attracted much attention, and had excited, in no small degree, the honest ambition and pride of the farmer.

As this casualty is unknown to the farmers in the vicinity, it may be conforming a favor if any of your numerous readers can throw some light upon it, and if a disease, point out a remedy. A.

REMARKS.—We should be glad to have an answer to the above communication from some of our experienced stock raisers, as we are not able at the present moment to give any satisfactory information relative to the nature of the disease which terminated so fatally.—Mr Colman is now absent on a journey to the west, and will not return for a few weeks: we trust therefore that we shall receive an answer from some other quarter for the gratification and benefit of the sufferer, and the public at large.

J. B.

LIGHTNING RODS.

"*Editors of the Cultivator*—Can you give your readers any information as to the best methods of preparing and putting up rods, as conductors on our buildings? There is scarcely a year in which great damage of property, and not unfrequently loss of life, is occasioned by lightning. I think farmers should have their barns protected as well as their houses, as experience shows that they are the most liable to destruction, at the time their contents are the most valuable, that is, immediately after harvest.

York Co. Pa. L. T. P."

In erecting rods for the protection of buildings from the effects of lightning, a few things must always be kept in mind, in order to ensure efficiency and consequent safety. As the point of erection, the most exposed and elevated part of the building, should be chosen. If a dwelling house, the chimney is the point that will require protection: if there are several of them, the most elevated one, the one most exposed to the general course of storms, as the westerly one; or if but one has a fire in it, that one will be found most liable to be struck by lightning, and will of course more require protection. Numberless recorded cases prove that all heated currents of vapor, whether rising from a chimney, or the masses of hay or grain in a barn, are excellent conductors of the electric fluid, and are to be considered as such in all arrangements for protection.

The materials to be used as the conducting medium or rod, is another point that should be attended to. Iron is the most generally used for this purpose, but copper is preferable, as it possesses greater conducting powers, is not liable to rust or fusion, and, being tougher, is not broken to fragments by an electric discharge, as iron sometimes is. The greater cheapness of iron, however, will probably continue its use, and when well put up, it gives all reasonable security. No iron rod should be used of a less diameter than three-fourths of an inch, and an inch rod is still better: as it must be remembered that the surface only has any effect in electricity, and, therefore, the larger the surface over which it passes, the less intense its action, and the less danger of breaking or fusion. A small

quantity of metal, if of the right kind, and a large surface given to it, will make a better conductor, than a larger quantity in an improper form. Thus, a copper ribbon, two inches wide, and of the proper length, will be superior to a copper wire of the same weight, as the process of rolling and flattening it, gives a much larger surface; and the same remark will be true in regard to iron. A number of small iron or copper wires, twisted into a rod, is better than a solid rod of the same weight, for the same reason; that is, a greater surface is exposed by the small wires than by the solid one, and this would be the best manner of constructing rods, were it not to be apprehended, that heavy discharges passing over wires would fuse and destroy them. Such have been recommended for ship conductors, as they would be entire, and flexible, and perhaps it would be found that the distribution of the fluid over such an extent of surface as such a rod would afford, would prevent the danger of fusion in any case.

In preparing the rod, the most essential thing is the making of the elevated points. These should be several in number, slightly diverging from the main rod, and the sharp points gilded or tipped with silver, so as to prevent their rusting, and losing, in a great degree, their conductive power. Perhaps the easiest mode of pointing them, is to make points of large silver wire, an inch in length, turning a screw on one end, and insert this into an opening drilled in the tapered end of each branch of the conductor, to receive it. If wire of the proper size is not convenient, they may be made by cutting them from a half dollar, and hammering them into the right form. If the rod is made in pieces they should never be put up by turning hooks on the ends, and connecting them in that way; as interruption to the fluid in its descent is frequently attended with bad consequences. The several pieces should be put together with screws, the connecting piece receiving the ends of two rods, and being as near the size of the conductor as strength and security will admit. The rod should never be secured to the building by metal staples or fastenings; or if such are necessary, the connection between the rod and these should be broken by pieces of glass, which is a non-conductor. Wood is the best for fastenings, and should only be used, except from necessity. It is not enough that the rod attract and receive the discharge; it must also conduct it to the earth, or no adequate security is afforded.

It has been estimated that a rod properly made, affords protection to five or six times the diameter of its height: that is, a rod standing six feet above a building, will protect the building for thirty feet around it. Instances have been known, however, in which a chimney having a column of heated vapor rising from it, has been struck, when within the limits usually considered safe, in a protected building. In such cases the result must be ascribed to the height, and conducting power of the vapor. The foot of the conductor should gradually recede from the walls of the building, and enter the earth to such a depth as to reach moist earth, and if the bottom of the rod is pointed, or split and parted different ways in the earth, the passing off of the fluid will be facilitated. No point should ever be allowed on a conductor.—*Albany Cultivator*.

Hon. D. Webster's farm, in Marshfield, Plymouth Co., Ms., contains a 1000 acres, and is one of the best in New England.

Massachusetts Horticultural Society.

EXHIBITION OF FLOWERS.

Saturday, June 20th, 1840.

"Now parting Spring,

Parent of beauty and of song, has left
His mantle, flower-embroider'd on the ground,
While Summer laughing comes, and lads the months
Crown his prime season with his choicest stores,
Fresh Roses opening to the solar ray,
And fruits slow-swelling on the loaded bough.

Here let my soul, amid ten thousand charms,
Lighted range,

Borne on devotion's wing, beyond the pole,
To highest Heaven, in thought; to Nature's God "

Our rooms, this day, were crowded with the choicest of Flora's handmaids: the "lovely Rose," and the "Pink with scent divine," were exhibited for premium, as our readers will perceive by the awards recorded below. Many other choice flowers graced the stands of the various exhibitions. The pot plants of Erica's, (nine varieties) Fuchsias as Bonvardia, Pimelia, and sent by Mr John Towne, added much to the general display; which, by the by, was equal to any former show.

A fine specimen of Magnolia, (Macrophilla) from Jno. A. Kenrick of Newton, was much admired.

The principal contributions of Roses, were from Messrs Johnson, John A. Kenrick, Wm. Kenrick, Winship, Howe, John Hovey, and S. Walker.

Of Pinks, Messrs Meller and Walker.

In the stand, of fine things from the Messrs Winships, of Brighton, we noticed a specimen of *Dria scabra*, one of the prettiest things we have seen for many a day. We said to our friend Story, "put us down" for a plant; and we to our friends—who love good things—get a plant.

If it was in our line we should do more than pay a passing notice to the fine seedling Strawberry raised by Messrs Hovey & Co. But this much we must say, that had our taste been consulted, to the same extent that our sight and scent have been gratified, we should have recorded them equal, if not superior to the best in the country.

Native plants by Mr. E. Wight.

The committee appointed to award premiums on Roses and Pinks, have attended to that duty, and adjudged them as follows:

Pinks—best display, to S. Walker;

Best Seedling, to S. Walker.

Mr Walker having entered for the best 6, and his flowers being the finest, the committee do not award any premium, but they would recommend that a discretionary premium of \$2 be given to Mr Meller for his fine display, as well as for some fine seedlings.

Roses—the best 50 blooms, to J. A. Kenrick;

2d best 50 do., to S. R. Johnson;

Best display of choice roses, to S. R. Johnson.

The committee would make honorable mention of the fine displays of Roses by Messrs Winship, R. Howe, John Hovey and Wm. Kenrick. Some of the flowers were as fine as any in the room.

C. M. HOVEY,
JOSEPH BRECK

From John A. Kenrick, Newton; 60 var. Roses. *Delphinium sinensis*; *Pæony whitejei*; *P. fragrans*; *P. humei*; *Gladiolis*; *Magnolia macrophylla*; *Pentstemon alba*; *Hemerocallis lutea*; *Spirea folius variegata*, &c.

From Wm. Kenrick, Newton; *Pæony*—reevesii, new pink color; *P. whitejei*, humei, fragrans, &c.; *Roses*, 30 kinds—*Iris pallida*, *Hispanica*

For the Committee,

S. W. WALKER, *Chairman*.

ON BREEDING IN AND IN.

"A difference of opinion may always be expected to exist, as to form and color that constitutes the beauty of animals, as well as vegetables, but it cannot be denied that the grand object of agriculture should be, a profitable produce. The mode of attaining this object, no doubt, will be determined in a great measure by peculiarity of situation and circumstances; but taking it for granted that every agriculturist must be desirous of keeping up the good qualities, if not of improving his stock, the only questions that can arise are,—What is an *improvement*? and what will produce *profit*? And let this be determined as it may, *perfection* can only be obtained by a selection of breeders. If a greater or less size be required, stronger propensities or greater and more perfect health and vigor, the object must be obtained by selecting and pairing those males and females which possess in the greatest degree the requisite qualities, whether crossing be resorted to, or breeding *in and in*. When left to nature, this is always determined one way; those which are rendered the weakest, from whatever cause, are driven off, or down, by the strongest and most vigorous; and as all have to contend with the same climate, lodging and food, those possessing the best habits must always prevail, and consequently, the breed must be kept up to its highest perfection. And in adherence to these principles—that which is most congenial to the laws of nature, is the most profitable—is clearly established by practical demonstration.

It is well known that there are many farms, and many large districts that never do fatten their stock, and indeed are considered and found inadequate to it. And what other cause can be assigned for this, but that the stock are bred by continual crossing with males reared under advantages of superior lodging, food, and climate, to what such farms and districts naturally produce? As Sir John Sinclair observes, animals bred from the same family and selected for their peculiar propensities to fatten, have a large proportion of flesh, and but little bone; so on the contrary, animals bred from meagre females, living in a harsh climate and with a scanty supply of food, by crossing with males of the largest size, produced by superior food, and in a climate more congenial, have a large proportion of bone, and but little flesh, and possess with a more delicate and precarious state of health. Any land whatever, that will furnish food enough to maintain two animals in a state for breeding and with a climate and lodging requisite to sustain health and vigor, will be found equal to the fattening an animal that had been naturalized to it by breeding *in and in* for several generations. Every

farm may be considered as having its peculiar advantages and disadvantages, compared with others; and profit can only arise from a skillful observance and management of these.

There does not exist a more mistaken notion, than that the stock of one farm may be kept equal to every other, by crossing and changing the animals and seeds only. It has been well observed, that nature provides every creature with a shelter from the storm. If a male and female of any species of animal or plant, be bred under circumstances of a congenial climate, and a liberal supply of food, and afterwards placed in a situation where the climate is harsh, and the supply of food scanty, they must of necessity decline in flesh, and in health and vigor; but their young, bred under those circumstances of privation, will acquire habits, and be reduced to a size more conformable; and these again breeding *in and in*, the habits of their progeny will still become better adapted, until by degrees they will become perfectly inured and naturalized, and capable of making the utmost return the farm is equal to, and at the least expense. But if, on the other hand, the breeder chooses to contend with, and oppose nature, and instead of submitting to her laws, he still persists in attempting to keep up the size, by a fresh supply of males and females from the original quarter, he inevitably must be subjected to the consequences of want of health and vigor, and incur great hazard and extra expense. That the above principles equally govern the vegetable, as well as the animal world, has been demonstrated by Sir Joseph Banks, who says, that by repeatedly raising plants from the seeds grown on the spot, he has so naturalized to this climate vegetables that were natives of a warm climate, and which, on their first introduction into this country, could only be kept alive in conservatories, that they are now enabled to flourish in the open air, without artificial protection."

Again: "After a perfect stock has been obtained, how is it to be continued? This seems to be the grand question, and it only can be answered on the principles before explained, viz. by duly attending to their qualities and habits, when selecting the breeders; and again, to the means by which these qualities and habits are sustained. If great size be the valuable quality, and the utmost which nature will admit of has been produced by an artificial climate and lodgings, and a selection of food, it must be obvious, that with the same climate, lodging and food, the same stock may be kept up breeding *in and in*; but with a less congenial climate, lodging and food, the progeny of such animals must decline, and become less in size; and at the same time it might be observed, that under these circumstances, no crossing can keep up the size and properties. And again, if animals or vegetables, of whatever size, bred in a certain climate, and with certain lodging and food, can be furnished with a lodging, climate, and food, more congenial and nutritive, they may be increased and improved by breeding *in and in*."—*Hayward's Science of Agriculture*.

New Wheat.—The Houston Telegraph says that a species of wheat indigenous to the country, has been discovered in the northwestern frontier of Texas. It is thought to be a valuable variety.

Destroy weeds while young, or they will get the upper hand, and be apt to keep it during the summer.

For the N. E. Farmer.

THE POWERS OF WATER.

MR COLMAN—In some preceding letters I have dwelt long on the general value of water, on the means of attracting it from the air, and of economizing it, by ponds and irrigation, on the earth. But on reflection I am sensible that I have not said enough on this important subject, to satisfy my inquisitive countrymen, who always ask for the reason of things. This inquisitiveness is the high road to knowledge, and ought to be encouraged from infancy through life. No reasonable man, especially in America, should rest satisfied with bare facts, when he has the means of penetrating to causes. It would be well for us that we should carry this spirit of enquiry into our laws, morals and politics; may I not add religion also? Can any system of religion be worthy of reasonable creatures, where *reason* is excluded, and the *utility* is not apparent?

It will be asked, probably, by many who do not understand the composition of water and its powers over other substances, how it can play so great a part in the composition of vegetable substance and life. To such enquirers I will here state what is already familiar to *vegito-physiologists*. There is a very ingenious apparatus at the ends of the roots of all plants for attracting water from the earth;—the leaves, also, have a similar power, and still more important functions. The root, in absorbing water, takes in various substances which water holds in solution, and transmits the whole through the ducts and cellular tissues of the plant, up to the leaves, which are the lungs of the plant, and qualify, by the aid of the air and light of the sun, these various substances for vegetable aliment; as the chyle, which is the essence of animal food, is by the aid of our lungs, and the air, prepared for animal nourishment. When the vegetable fluid is thus carried up, and prepared by the leaves, it then descends into the plant, depositing each article in its appropriate place.

As the decomposition and analysis of vegetable substance discovers various ingredients, minerals, oils, salts, &c., they must have been carried there by the air, or the water, or by both. They could not penetrate the roots without the aid of water any more than dry salt could penetrate meat without the aid of moisture of some sort. There is one substance which, as it appears to be the basis of vegetable construction, is worthy of particular notice. It is called carbon, or charcoal. Every one may see that vegetable substance divested of its aqueous, oleaginous, resinous and volatile parts, by the tempered action of fire, makes charcoal—that is, charcoal only remains. This is the frame-work of the vegetable kingdom; therefore carbon, or the constituent of that frame-work, is well worth our attention.

This carbon is brought up in the water from the earth, as well as obtained from the moisture of the atmosphere. It is blended with other substances, all which are necessary for the nourishment of the plant; but it cannot escape, and take its appropriate place in that formation, until that little wonderful *elmbic*, the leaf, has decomposed the mass of composite fluid in which it is contained. When this decomposition and distillation takes place, the oxygen gas with which it is combined in the water, is set loose, flies off, and the carbon is then free to take its place in the vegetable body.

Now as this principle of carbon, in the state of carbonic acid, is abundant in the air, or more properly, perhaps, in the water of the air, the useful attraction of water from the air must be apparent, since it brings with it so important a part of vegetable nourishment. Those who have not looked into these matters, and who might have doubted of so much of vegetable aliment coming from water, will now begin to understand its importance; and may be inclined to believe the story I told in a former letter, about my potato crop in France.

It may be asked by the uninitiated, for whom I now write, how this water gets into the air; carrying with it minerals, oils, resins, salts, carbon, &c. And here we may contemplate with grateful admiration, the wonderful resources and fruitful means of nature; all tending to what we finite beings call *ends*; but which are, really, nothing but links in that great, circular, endless chain, which envelopes us and all things. The heat of the sun attenuates the water of rivers, ponds, lakes, and the ocean; and reducing it to vapor without decomposing it, chemically, renders it light enough to float in the air, from whence it descends by being cooled again, or whence it is attracted by the leaves of trees, and green vegetables generally; or from whence it may be abstracted by some other means, at the command of man, as we are lately informed by Mr Espy, the new professor of meteorology.

I will now refer my readers back to my former remarks on the importance of keeping the ground generally, and more especially highlands, well covered with living vegetation, and of *close* cultivation rather than *expanded* cultivation. I may expatiate at another time on close cultivation; for I am now informed that several useful experiments have been tried on the relative yield of small and large quantities of ground, where the same quantity of manure has been used on each. But these experiments, I understand, were made principally with a view to the saving of manure; whereas, there are various other considerations worthy of notice; such as taxes, fencing, interest of money on a large field, the waste of time and shoe leather in going over it, ploughing, reaping, &c. And all these considerations, without mention of the advantages of more moisture, and its vegetable contents attracted from the air by a system of close cultivation.

I will conclude this letter by reminding your readers of a still more abundant source of vegetable nourishment, whose importance may now be more apparent, since they now understand what water is, and what are its powers, combined with leaves and light.

If your readers give but a moderate share of credit to this supposed power and value of water, will they allow the smallest brook to pass over, or the smallest pond to stagnate on their land, without depositing some of their rich treasures; without paying that tribute to enlightened industry which is its just due? I trust, sir, they will not; and that your wide circulating paper will refresh the land with fruitful showers and fruitful streams of knowledge in all its branches; for society itself, with all its attributes, is but one great farm, on which we are all destined to dig, and plant, and harvest home, to consume and be happy.

Your friend and humble serv't,

WM. FOSTER.

Employ your leisure in some active virtue, and melancholy will be a stranger to your breast.

For the New England Farmer.

CANKER WORM.

Raising fruit is of first rate importance among objects pursued in procuring the pleasures of taste and the real comforts of life.

Riding in the car from this city to Worcester, I could not without pain look on the apple trees, strip of their agreeable foliage and attired in the badges of desolation. I am confident this intrusion of an unsparring enemy may be easily and promptly resisted at the threshold. I will venture myself at the straits of Thermopylae and sustain an onset from the whole posse comitatus.

Now, brother farmers, I have tried some experiments and find those which consume the least time and produce the greatest effect are most to be prized. How long do you think it will take you to fix a syringe of convenient calibre to exercise with most adroitness? Now when you have done this, place yourself on the windward side of an apple-tree and dip the proboscis of your syringe into a bucket of water saturated with lime, and discharge the contents into the air so that they may fall upon the leaves, and the whole enemy will immediately decamp, leaving the rightful owner in quiet possession. I have tried the experiment on various worms that invade the trees, and have not known it fail of producing an expulsion.

It is extremely probable that a decoction of tobacco or any powerful narcotic, or bitter substance, will be attended with the same result.

For the N. E. Farmer.

CANKER WORM.

MR BRECK—It has occurred to me that a saving of labor and expense may be made by those who prefer tarring for the protection of their trees, to the new mode of leaden or tin troughs filled with oil.

Place round the trunk of the tree, from 3 to 5 feet from the ground, a tin collar, nearly horizontal, 5 inches wide, the inner edge cut in strips and turned up vertically, to fasten to the trunk by small nails: stuff the space between the collar and the trunk with tow, cotton or similar substance. Tar the under side of the collar: it will last long, will not run on to the tree, and can be renewed with ease. The cost would not probably exceed 4 cents per tree. Respectfully,
L. X.

Dorchester, 15th June.

P. S.—This plan will answer for orchards and for trees with grass round them, and appears to me in every way more effectual than the German method, which Mr Vose detailed in your last number.

To preserve Hams for Summer use.—Take a dry cask, put a good layer of coarse salt in the bottom, and then put down a ham—cover that with coarse salt, and put down another ham, and so on till the cask is full or the hams all deposited. Set the cask in a cool, dry place, and whenever a ham is wanted, take it out, and it will be every way as clean, clear from vermin and all other impurities, as when put down. This is attended with very little trouble or expense, as the salt is not at all injured for any other use in the fall. My cellar being a very dry one, we put the cask of hams in a cool place in that; but a damp cellar would be apt to dissolve the salt. The hams should be well dried before being put down.—*Corr. Albany Cult.*

PAWTUNET FAIR, 1840.

The Standing Committee of the Rhode Island Society for the Encouragement of Domestic Industry have arranged as follows, to wit:

That the next annual meeting of the Society be holden at Pawtuxet on the 2d Wednesday of September next.

That the Society, for this present year, dispense with the Ploughing Match and the exhibition of Stock, and all other articles, except Butter.

That premiums to the amount of \$200 be awarded on the following subjects, and committees appointed accordingly to report thereon, at an adjourned meeting of the Standing Committee, to be holden on the 3d Wednesday of January, 1841.—Every applicant for a premium will make a written statement, and forward it by mail or otherwise to the city of Providence, directed to the Secretary of the Society, on or before the 1st day of January, 1841.

PREMIUMS OFFERED.

For the best Butter, to be presented in kegs, and in kegs only, of not less than 50 lbs. each, with a written statement of the general process of making—the kind and quantity of salt used to each pound of Butter.	\$20
For the next best,	12
For the next best,	8
For the next best,	6
And for the next best,	4
For a satisfactory and the most satisfactory statement in writing, of the expense of raising any kind of Grain crop, showing the least cost per bushel. The soil and subsoil on which the crop is raised must be named, and the cost stated as follows:	
Rent of land for one year,	
Quantity and kind of manure—loads at,	
Ploughing, Harrowing and Rolling—days at,	
Planting or sowing—days at,	
Tillage—days at,	
Harvesting—days at	
First premium,	\$10
Second,	6
Third,	4
	\$20
For a satisfactory and the most satisfactory statement showing the value of Apples, or any kind of Root compared with Indian Corn per bushel, as food for Cattle, Horses, Sheep or Swine,	\$10
Next best,	6
Next best,	4
	\$20
For a satisfactory and the most satisfactory statement of the expenses, product and value of Millet raised for fodder,	\$10
For a satisfactory and the most satisfactory statement of the expense of raising and the value of a crop of Indian Corn sowed broad-cast, and used for soiling cattle, or fed to sheep, horses, or swine,	\$10
For a satisfactory and the most satisfactory statement of the expense and effect of ploughing in green crops as manure,	\$10
For a satisfactory and the most satisfactory statement of the effect of mixing Lime with Peat, and Lime and animal manure with Peat for manure—stating the cost and value per load,	\$10

For an approved and the most approved statement of the comparative profit of fattening Sheep or Swine upon the product of a farm,

\$10

For an approved and the most approved statement of the manner of reclaiming bogs, with a minute statement of the depth, manner of performing the work, with all expenses, and the increased value of the land,

\$10

For a satisfactory and the most satisfactory statement of the expense of under-draining that kind of land where the top soil rests upon a subsoil of hard pan, so retentive of water that it cannot be ploughed until late in the season,

\$10

For a satisfactory and the most satisfactory statement of the effect of putting clay upon light land, testing the effect of Plaster of Paris before and after the application of clay,

\$10

For a satisfactory and the best experiment in raising the White Ash from the seed.—(The second growth of Ash is the only timber fit for the construction of carriages: being light, strong and elastic.)

\$10

Amounting to \$180

At said annual meeting a dinner will be provided, the expense of which for each person attending, shall not exceed one dollar.

Immediately after dinner the following subjects are recommended as topics for discussion or conversation, and all persons who may be present are requested to communicate such information as they may possess upon the several topics, in the order in which they shall be proposed by the President of the Society.

1st. The general properties of those articles employed by the farmer for manures, viz: animal manures; such as fish, train oil, &c. Manures of a mixed character, viz: those afforded by various animals. Vegetable manures, such as peat, pond mud and turf—and mineral manures, such as lime, gypsum, ashes, salt, &c.

2d. The experience of farmers present in regard to the best mode of increasing barn yard manure, and the most profitable application of it to the soil.

3d. Peat and pond mud. What experience in using it?

4th. Fish. What experience in using it, and how used?

5th. Urine of cattle. What experience in using it, and how used?

6th. Indian Corn. What is the average crop of our Indian corn? What is the best mode for manuring for it, spreading and ploughing or putting it into the hills, or both, and what kind of manure, long, and unfermented, or short? What is the best mode of planting? In hills, and if so low near; or in drills, and how far the rows should be apart, and how near the corn should stand in the drills? Cultivation: how often to be hoed, and whether hoed flat or hilled up? What experience in the use of the cultivator? Gathering: Is it best to top it, and when? Or to cut it up near the roots and stock it in the field to ripen, and when?

7th. Potatoes. What is the average crop? What is the best sort? Planting: Large or middling size? Cut or whole? In hills or drills, and what distance?

8th. Rye. What is the best kind, spring or

winter? How cultivated to best advantage, and what the average crop?

9th. Wheat. The success and modes of its cultivation?

10th. Grass. Best kinds for each kind of soil? Best top dressing for the same? Best mode of manuring in all respects, and average crop?

JAMES RHODES, President

Wm. W. HOPKIN, Secretary
Providence, April 8, 1840.

From the Albany Cultivator.

REARING CHICKENS.

MISSUS ENVOIS—Having made some experiments in the raising of chickens, a business that forms a part of every farmer's occupation, I send you a description of my present plan of operation, which appears to answer admirably. Under an out house 16 by 18 feet square, raised 3 feet above the ground, I have dug a cellar, 3 feet below the ground, making the height 6 feet altogether. Eight feet in width of this cellar is partitioned off for turkeys, the remaining, 10 by 16 feet, being sufficiently large to accommodate 100 chickens, or even more. This cellar is enclosed with boards at present, but it is intended to substitute brick walls in a year or two. The roost is made sloping from the roof to within 18 inches of the ground or floor; 12 feet long by 6 feet wide. The roost is formed in this way; 2 pieces of 2 inch plank, 6 inches wide and 12 feet long, are fastened parallel 5 feet apart by a spike or pin to the joist above, the lower end resting on a post 18 inches above the ground. Notches are made along the upper edge of these plank, one foot apart, to receive sticks or poles from the woods, the bark on. When it is desirable to clean out the roost, the poles being loose are removed; the supports working on a pivot are raised and fastened up, then all is clear for the work of clearing out. I next provide the chickens with corn, oats, and buckwheat, in 3 separate apartments, holding about half a bushel each, which are kept always supplied. They eat less, I find, if allowed to help themselves to what they want than if fed to them in the usual way; for in the latter case each tries to get as much as it can, and thus burdens itself, but finding in the former case that they have abundance, they eat little and that generally in the morning early, and in the evening going to roost. I have 60 chickens, and they eat about 6 quarts per day of the three kinds of grain, in the proportion of twice as much corn as buckwheat or oats. In the roost is also a trough of water, renewed every other day; burnt oyster shells, shell-marl and ashes. A row of nests is constructed after a plan of my own, and does well. It is a box 10 feet long and 18 inches wide; the bottom level, the top sloping at an angle of 45 degrees to prevent the chickens roosting on it; the top opens on hinges. The nests, eight in number, are one foot square; the remaining six inches of the width is a passage way next to the wall, open at each end of the box, and another opening midway of the box. The advantage is to give the hens the apparent secrecy they are so fond of.

When fed plentifully in the winter hens lay enough eggs to pay for the grain, and in the spring they will repay fourfold.

E. H. VANUXEM.

Long Branch, N. J., Feb. 17, 1840.

NEW ENGLAND FARMER, AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JUNE 24, 1840.

AGRICULTURE IN MASSACHUSETTS.

At a distance from home and keeping no copy of our former remarks, we are not certain that we may occasionally be chargeable with some repetition. It will not however, be done, if done at all, with malice *prepense*, and therefore we shall in such case feel that we are content at least the common claim upon the kindly and candid of our readers.

We alluded in our last to the fact that, properly speaking, no capital is invested in farming in Massachusetts; and although capital might often be invested in this way to great advantage, the study of our farmers is to get on with as little expense as possible; avoiding any expenditure not only where the result might seem to be doubtful, but where even it is as certain as any thing future can be. We were much impressed with this circumstance when the law authorising a bounty upon wheat was enacted. Though the bounty proposed was only two dollars for the first fifteen bushels, and five cents for each additional bushel, and seemed in truth a very small affair; yet it was argued that the bounty would at least pay for the seed; and that this circumstance would prove, as facts afterwards showed, a sufficient inducement for many to sow wheat who otherwise would not attempt it. This indicates a remarkable caution, which many would pronounce a meanness. We think it very far from being a meanness; but a caution, which springs from commendable motives. But at the same time it evinces a want of enterprise which we may pronounce excessive; and which operates as a strong impediment to agricultural improvement.

There are certainly many cases in which capital within reasonable limits might be invested to great advantage in agriculture. The rock on which many of our farmers have grounded, has been, where money has been laid out in expending too much upon their buildings and fences, upon the exterior embellishment and the interior furnishing of their houses. In this matter there is certainly too great ambition of display; and many of our farmers have houses which cost them four, five and six thousand dollars, which often exceeds by fifty and seventy-five per cent. what the cost in such case should be; brings upon them too often a heavy debt, and effectually cripples or destroys their means of improving their lands. The difference in this respect between the New England people and the New York farmers or the farmers in the western States is remarkable. In New York State the first object of the farmer is the improvement of his land and the cultivation of crops; his house is often a very inferior concern, and all his equipments of the cheapest and most simple character. In the western States even the richest farmers will be found living in log cabins; and a frame house with all its various comforts and elegances, is a luxury which hardly presents itself to his imagination in the most distant prospect. Whatever money he acquires beyond his absolute wants, is expended in buying more land, in enlarging his stock, or in multiplying his crops. It must certainly be pronounced a very bad policy for a farmer, where his house on a farm of one hundred acres costs him much more than his land. It is very bad policy, because the money thus expended becomes not only an unproductive but a deteriorating capital, because it leads to various other expenses in maintaining a certain style of living in keeping with the appearance and size of the house;

because in the next place in case of a necessity of the sale of the farm, either on account of death or misfortune, such extraordinary expenditures are scarcely considered at all; and lastly, because it deprives him in a great degree of the means of culture and improvement. We admit that in this case there has been within the last quarter of a century an evident improvement, and instead of the large square two story and oftentimes three story houses, which were so common in the country, and which were seldom built under an expense of thousands, many both of our farmers and mechanics are content to build neat one story houses, at a cost of seven or nine hundred dollars.

There are other circumstances of expense, which arise out of our manners, and in which it may, with too much truth, be said we pay dear for our pride. We will refer to one prominent example, and that is in respect to our carriages or pleasure vehicles. Any one who has travelled in the interior of New York, as in the neighborhood of Albany, for example, will have often seen the Dutch farmers, men of wealth and condition, going to market with wheat or other produce in their farm wagons, or bringing home from town a load of supplies, and their wives and daughters, though exceedingly well dressed, getting up along side of them. How totally different are things with us in a large part of Massachusetts, where hardly the farmer himself, if he is above the condition of a day-laborer, much less his wife or daughters, would ever think of going to the city or from one town to another in a vehicle of burden; and where men whose means are extremely restricted, deem it essential to their condition to keep a chaise or carriage exclusively for travelling. We do not speak of these things in the way of censure or otherwise; and allude to this example among many others, which show by what occasions the means of agricultural improvement with many of our farmers are crippled or destroyed.

We can have no disposition to see our farmers living in rude log cabins or hovels or deprived of a single luxury or comfort to which they may aspire as the fruit of their honest earnings. We rejoice indeed in every refinement, elegance, or improvement of their condition; but we deem it a cardinal error to sacrifice substantial improvements to matters of mere embellishment; and to adopt any manners or habits which would seem to imply any distaste for the circumstances of our condition, or an opinion that there can be any degradation in any thing except meanness or vice, or in any mode of honest frugality.

We have other topics in connexion with the subject under consideration, upon which we cannot now enter, without taxing too severely the indulgence of our readers.

H. C.

CONGRESS.

Congress have now been in session nearly seven months; and in looking back upon the course pursued, it is difficult to point to any great measures of public utility, to which their labors have given birth. As the country grows older, the sessions of Congress, unless where prohibited by the constitution, may be expected to be continually lengthened, until presently they become a permanent assembly. It is but right and just that those, who give up their time to the public business, should be fully compensated. It would not be advisable to abolish all pay, because then only the rich could afford to accept the place; and many of the best informed and most useful persons would be incapable of serving; but it is greatly to be regretted that there are those persons who are anxious to protract the session of Congress only for the sake of the per diem allowance. For ourselves we are frank to confess that we have little

hope of the country. We do not mean to say that we fear any signal catastrophe; any rupture of the union; or any extraordinary attack or encroachment upon public liberty. But patriotism, honest, unmix'd and disinterested patriotism seems to have departed; and ambition, selfishness, and a spurious devotion to the public cause and one's own personal interests are too much the order of the day. We mean no disrespect nor would we imply any distrust of many eminent men both in public service and out, whose talents and virtues are alike, a blessing and an ornament to the country; and who, beyond a doubt, in any signal emergency would hesitate at no sacrifice for the public good; but such men rise infinitely above the vulgar herd both of ins and outs, whose impulses are wholly selfish, and who seek nothing save their own emolument.

H. C.

WHEAT.

Great complaints are made at the south and west of the destructive ravages of the Hessian fly. This is a severe scourge; and against it no remedy has been discovered. Early sowing has sometimes succeeded; late sowing has sometimes carried the wheat beyond the time of the fly; but his hatching is at best twice a year; and his hiding place is so concealed and secure, that there is no reaching him with any common application. Every plant which grows has its peculiar enemies; and yet in spite of the Hessian fly, the grain insects, the weevil, the wire worm, and a host of others, divine Providence takes care that industry, perseverance, and faithfulness shall never want bread.

H. C.

THE SEASON

At the West has been uncommonly wet—rain after rain has come; the rivers are at their height; the meadows have been flooded; the fields watered to excess. If the corn is backward, oats and all the grasses exhibit an extraordinary luxuriance. Dr Holokey's record shows about an equal quantity of aqueous vapor as falling each year, so that if the spring be excessively wet, we may look for a warm and dry autumn.

H. C.

BETTER SUGAR EXPERIMENT.—A farmer from Genesee county, whose name we have mislaid, gave us a verbal account of a small experiment which he tried the past season, in making sugar from beets.

He took two barrels full (about 5 bushels) of yellow and white sugar beets to a cider mill, and ground them and pressed out of them a barrel of juice. This he boiled down in the same manner as for maple sugar, and it yielded twenty pounds of good sugar. A little milk and the white of an egg was put into the syrup to clarify it; but the sugar was of a dark color, and evidently requires some other process to purify it. He is convinced that beet sugar can be made with profit by common farmers, without any other apparatus than a common cider mill and press, and two kettles. He intends to try a larger quantity this year, and hopes to succeed in making a better quality of sugar.—*Genesee Farmer.*

MASS. HORTICULTURAL SOCIETY.

EXHIBITION OF VEGETABLES.

Saturday, June 20th.

By James L. L. F. WARREN, Brighton—Hill's early peas, seven weeks from planting.

For the Committee,

RUFUS HOWE.

There was a large and splendid display of flowers at the Horticultural Rooms on Saturday last. The report of the exhibition on that day may be found on another page of this paper.

BRIGHTON MARKET.—Monday, June 22, 1840.

Reported for the New England Farmer

At Market 200 Beef Cattle, 15 pairs Working Oxen, 40 Cows and Calves, 1500 Sheep and 230 Swine. About 40 Beef Cattle were left a few miles from the market and were not offered for sale.

Prices.—Beef Cattle—A small advance was effected. We quote Extra \$6 75. First quality, \$6 25 a \$6 50. Second quality, \$6 00 a 6 25. Third quality, \$5 25 a \$5 75.

Working Oxen.—No sales noticed.

Cows and Calves.—Sales \$20, \$23, \$27, \$31, \$37, \$40, and \$42.

Sheep.—Dull. Lots sold at \$1 25, \$1 42, \$1 75, \$2 25, \$2 50, \$2 66, and \$3 00.

Swine.—Two lots of small pigs were sold at 6. At retail from 4 1-2 to 7.

DORKING FOWLS.

For sale, a few pairs of pure Dorking Fowls. The stock, of which these are the produce, were procured in Dorking County of Surrey, England. A few breeds have a title to Lots of so high and long continued a reputation as the Dorking. Upwards of fifty years have passed, since, while resident in Surrey, I sent to Dorking for my first regular breeding-stock; they were then the ancient and superior five-clawed breed of Surrey.—*Marbury on Poultry, 7th Edition.*

This breed attains to a large size, and the hens are the best of layers. Price \$3 per pair. Apply to **JOSEPH BRECK & CO.** June 24.

OSTRICH FOWLS.

For sale, a few pairs of this largest breed of domestic poultry. The hens are good layers and the eggs of the largest size. The male, of which these are the produce, weighs more than eight pounds in common condition, and he is not quite a year old. This breed, as well as the Dorking, makes good capons. Price \$5 per pair. Apply to **JOSEPH BRECK & CO.** June 24.

PURE BLOOD BERKSHIRE PIGS.

The Society of Shakers at Harvard, Mass., have for sale the Pure Blood Berkshire Pigs. Also, a lot of Berkshire cross with other Breeds, on reasonable terms at their Village.

Persons wishing to be sure of the clear Berkshire breed may rely on those they offer for sale, as they are the progeny of some of the latest imported from England. June 24.

DISHLEY SHEEP.

For sale, twenty full blood Dishley or New Leicester Ewes, and one Ram. Price \$10 each. Apply at the Farmer Office. June 24.

SCYTHES, RAKES, &c.

The subscribers offer for sale a very extensive and complete assortment of Scythes, Rakes, &c. consisting in part of 300 dozen Phillips, Messer and Colly's superior Scythes. 50 " Metcalf's do do. 50 " Tait's cast steel do do. 25 " English do do. Grass do. 10 " do do do. Cradle do. 100 " Hall's Rakes, superior. 100 " Wilder & Eddy's do do. 200 " Common do do. 100 " Clapp's patent Scythe Snaths, 50 " do do do do do. 100 " Common do do do. 2500 " Austin's superior Rifles. 2000 " Common do. 1000 " Scythe Stones. 100 " Grain Cradles superior.

They would respectfully call the attention of Dealers and agriculturists to the above assortment, which consists of many of the best kinds now in use, and which they are prepared to sell at the very lowest prices.

JOSEPH BRECK & CO.

New England Agricultural Warehouse and Seed Store, 51 52 North Market Street. May 20.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and horse, with a boy to lead, will rake on an average from 25 to 30 acres per day, with ease, and do the work well. They are coming into very general use in all parts of the country, and will, in a few years, supersede the use of the common hand rake. There is a great advantage in this rake over all others, as the person using it does not have to stop the horse to unload the rake.

GRAIN CRADLES.

The Grain Cradle is an article which is coming into very general use in the New England States, where they were till of late but little known, although they have been in very general use in the southern and western States, for many years, and which is found to be decidedly the best mode of harvesting grain, as it is supposed one man will cradle five acres in a day when he cannot reap more than one. The difference in gathering a crop is so much in favor of cradling, that we must suppose that it will be the only mode adopted hereafter, and the grain cradle will become of as much use, as an implement of husbandry, as the plough now is.

There has been a very great improvement in the manufacturing of this article, they are now made on the most improved plan; the scythe is well secured and finished in a superior manner and made of the best cast steel.

NOTICE.

The Rhode Island Society for the encouragement of Domestic Industry, have procured copies of Dr Jackson's Geological and Agricultural Report of Rhode Island, and will deliver the members each a copy gratis, by calling on E. Cranston & Co. at their Bookstore in Providence.

WILLIAM RHODES, Treasurer.

Rhode Island, June 24.

A Half Blooded Cream Pot Bull Calf for Sale.

Calved April, 1840. Dam, a first rate native cow, and got by Col. Jacques' famous Bull, Don Cream Pot. This Calf is a deep red color, and strongly marked of the Cream Pot breed. Apply to **JOSEPH BRECK & CO.** Dorchester, June 21. 3w

WANTED

To hire for a term of years and at a moderate rent, a Farm of 15 to 30 acres arable land in good condition, with a good barn and water for cattle and privilege of cutting fuel. The distance from Boston not material. Apply at this office. June 17. 1t

SUPERB ROCKET LARKSPUR SEED.

The subscribers offer for sale a quantity of Superior Double Rocket Larkspur Seed, of their own raising, sown from double flowering plants only, embracing all the different colors. For fine, strong and early plants, the seed should be sown in August. **JOSEPH BRECK & CO.** June 17.

(Continued from page 423.)

Southport in Wisconsin, 55 miles from Chicago, is a smart little village, off which we stopped to take in passengers. The west shore of the lake is generally low and well timbered, but a few miles inland the country is mostly prairie. Racine, 67 miles from Chicago, is a small village, very handsomely situated upon a high bluff. It has a few good houses, and makes a good show toward the lake.

About sunset we came to Milwaukee, the largest town in Wisconsin, and the handsomest on Lake Michigan. The town is situated inside the bluff near the mouth of a considerable river, and cannot be seen upon the lake except from the south. The sandbar at the entrance of the river prevents large vessels from going up to the town, and a small steamer is used to put on board and take off passengers from the lake boats, and also to tow out flats laden with wood for their supply. The houses are nearly all painted white, and the town has a fresh and beautiful appearance. The country around is broken and heavily timbered.

The next morning we were in the middle of the lake and out of sight of land: we saw several large vessels, one of them a ship, and I could hardly realize that I was traversing a fresh water lake, and was not upon the wide ocean. About noon we made the Manitow islands, where we stopped to wood, and while the hands were engaged in that business the passengers spread themselves upon the beach, which is covered with smooth rounded pebbles, perfectly clean and free from any particle of mud or sand. These islands belong to Michigan and are little else than sand hills, which shoot up to considerable height, and many of them are naked peaks, resembling chalk cliffs at a distance; between the hills the land is swampy and produces several species of pine. The water of the lake is of a pale green color, though a small quantity taken up in a glass appears colorless, and it is so very clear that the small pebbles at the bottom of the lake may be distinctly seen at a depth of more than twenty feet. In the afternoon we passed the Fox and Beaver islands and came to the straits in the evening, and about 11 o'clock we discovered Indian fires, and presently came to the village of Macinaw. There several of our company went on shore: the village consists of 20 or 30 buildings in a little bay on the south side of the island. There is a fort and a lighthouse at this place, and a part of the stockade still remains which formerly enclosed the trading house.

The next morning we were at Presque Isle taking in wood, and we were here supplied with trout weighing from 10 to 30 lbs.: the price for fresh trout is four cents per pound, and pickled nine dollars per barrel. The land on the shore is low and produces the pine, cedar and other evergreens, and further inland, birch, beech, &c. The few people who inhabit this place live by fishing and preparing wood for the steamers. The water of lake Huron is like that of Michigan in color and clearness, and both lakes are very deep.

The morning of the fourth day we were at a woody station on St. Clair river, seven miles below Fort Gratiot.

The shores on both sides of the river are studded with farm-houses and exhibit considerable improvements. We passed several very neat villages, particularly Palmer and Newport on the American side, and Sutherland on the Canada side.

The entrance into lake St. Clair is very shallow, and passing over the flats our boat roiled the bottom considerably. The shores here spread out into broad wet marshes formed by the deposits of the river and by the same process, the whole lake will at some distant period be filled, leaving only the channel of the river. Lake St. Clair is of triangular shape and about 20 miles long. Coming into the river again, the farms along the shore have a very good appearance; the houses are generally painted; there are good barns and thrifty orchards, the whole exhibiting an air of neatness and comfort.

Detroit makes a handsome show as seen from the river above: its brick edifices and church steeples give it an imposing and city-like appearance, very pleasing to a traveller coming from the west. On our arrival at the wharf I walked up into town; the site is a large swell of land not very elevated, but sufficiently so to make it healthy and pleasant; the streets are wide and paved, the principal ones running parallel to the river, and these crossed at right angles by others running from the river; the buildings are principally of brick, many of them very stately, and most of the dwellings have little gardens in front ornamented with trees and bowers.

Sandwich, on the opposite shore, a settlement older than Philadelphia, is a small dull looking village; the houses are chiefly of wood, and the whole appearance of the town is gloomy, and the sentinels treading the streets and landing with measured steps, contribute to give a stranger an unfavorable impression. The contrast between the two places is striking. The ferry boat seems to be an affair of compromise: it is named "Unted," and displays both the British and American flags.

Below Detroit the shores are studded with farm houses and gentlemen's seats, and the country appears to be well cultivated, and from the appearance of the crops I should judge that the soil is excellent.

The flag of England floating in the breeze, the extensive fortifications, and the red jackets and gleaming bayonets of Victoria's serving-men, apprised us of our approach to Malden, one of the strong holds of Upper Canada. The town is of small extent and has a crowded and ancient appearance; most of the houses are of wood and without paint; there were no vessels at the landings nor any thing about the town which indicated much business. As we passed we caught a glimpse of a large body of soldiers in motion in the principal street.

Two miles below Malden we passed into lake Erie. When I awoke the next morning we were in the harbor of Cleveland, having touched at Sandusky in the night. The port of Cleveland is at the mouth of a creek: on the west side the land is very much broken, and the buildings on that side are scattering; the principal part of the town is on the high table land on the east side, and is not seen from the harbor. The numerous hotels and large warehouses indicate an extensive business. On passing out into the lake we had a good view of the upper town, which appears to be well built and shows to good advantage.

Twenty miles from Cleveland we came to Fairport, a thriving little town of considerable business. The principal warehouses are at the pier, and the most of the town lies snugly ensconced in a little valley a short distance up the creek.

Twentyeight miles farther brought us to Ash-tabula. The port like all the others on this lake, is at the mouth of a creek, where are the principal

warehouses: there are also a few good houses on the bluff west of the pier and facing the lake; but the principal village is two miles up the creek.

(To be continued.)

An attorney named Else, rather diminutive in his stature, and not particularly respectable in his character, one day met Mr Jekyll. "Sir," said he, "I understand you call me a pettifogging scoundrel: have you done so, sir?" "Sir," said Jekyll, with a look of contempt, "I never said you were a pettifogger or a scoundrel, but I said you were *little Else*."

The Philadelphian says, a Mr Day, in an eastern paper, advertises the loss of his dog. We wish he may get him. "Every dog has his day"—and every Day ought to have his dog.

There are 12,000,000 barrels of flour consumed yearly in the United States, which at \$5 per barrel amounts to \$60,000,000.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

Orders for Bone Manure or Oyster Shell Lime, left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

March 4, 1840.

NAHUM WARD.

Week's Treatise on Bees

For sale by JOSEPH BRECK & CO.

April 15.

NEW AMERICAN GARDENER.

FOURTEENTH EDITION.

The New American Gardener, containing practical directions on the culture of Fruits and vegetables, including Landscape and Ornamental Gardening, Grape Vines, Silk Strawberries, &c., by Thomas G. Fessenden, late editor of the New England Farmer. For sale by JOSEPH BRECK & CO., 51 and 52 North Market Street.

May 13.

CARNATION SEED.

The Subscribers have received from Rotterdam, a small quantity of extra fine Carnation Seed, saved from one hundred choice varieties, which they offer at 25 cents per paper. We have tried it, and find that it vegetates freely. It cost us 30 guilders per ounce, and from the representation made, no doubt will give satisfaction to those who may be disposed to try it. We have also very fine carnation seed at 12½ cents per paper. The seed may be sown with good success any time in May or June.

May 20.

FOR SALE.

For sale a fine heifer calf, from one of the best cows in the country, and by the celebrated Ayrshire bull imported by Mr Cushing. Inquire at this office, or at Winships' establishment at Brighton.

May 20.

HORTICULTURAL TOOL CHESTS.

Containing a complete set of Garden tools of superior finish and style, recently received from Liverpool and for sale at the New England Agricultural Warehouse and Seed Store.

May 6.

JOSEPH BRECK & CO.

GARDENERS KNIVES.

JOSEPH BRECK & CO. have this season imported and now offer for sale a few very superior Garden Knives, for pruning, &c. manufactured expressly for Gardeners, and warranted superior to any article of the kind before imported.

Also—a large assortment of Edding Knives, Grape Sissors, &c. &c.

April 22

WANDERINGS IN THE WEST IN 1839.

No. VI.

(Continued from page 428.)

The shore of lake Erie appears to be very level, not very much elevated, and covered with very heavy timber, and except at the towns there are very few clearings: the scenery is very uniform—a steep bluff facing the lake crowned with the unbroken forest: there are numerous islands in the lake, generally rocky and uninhabited.

Thirteen miles from Ashtabula we came to Conneaut, upon a small creek near the Pennsylvania line. Here, as at the other places, is a pier with a few warehouses, and the principal village is two or three miles up the creek upon the stage road. Our stop at all these little towns was too brief to allow us to go on shore.

Twenty-five miles from Conneaut and 86 from Cleveland, brought us to Erie in Pennsylvania, which is situated upon a high, airy spot: it is well built, chiefly with brick, and has some very fine edifices; the harbor is the best upon the lake, being formed by a low peninsula, nearly in the form of the letter T. It was here that Perry's fleet wintered after his great victory, and the wrecks of his prizes were sunk. Our stop at Erie was long enough to allow us to go over the town, the thriving appearance of which pleased me much.

From Erie the country assumes a bolder appearance; high and sometimes rocky hills are seen, which distinguish the territory of Pennsylvania from that of Ohio.

When I awoke the next morning we were safe in port at Buffalo, having been a little less than five whole days coming from Chicago, a distance of 1050 miles.

Buffalo is a large well built city, has many splendid public buildings, and contains probably 25,000 inhabitants, and it seems hardly possible that such a city could be produced in the short period of twenty years, yet that is the fact: the little village which previously stood there, was wholly burnt by the British in 1813. Its situation for business and trade is peculiarly favorable, being at the extreme east end of the lake, and the termination of the great New York canal: it thus becomes a thoroughfare from the eastern States to Canada and the west. The number of steamboats and sailing vessels going and coming is very great. The rapid growth of the city is owing to these circumstances.

From Buffalo I took the cars to Niagara falls, distant 23 miles. I spent about four hours only at the falls, but I made the most of that time. At the first view of the cataract I was disappointed; it did not appear so grand as I had expected, but it was because that I was not able to realise the magnitude of the scene. After looking at it from different points I was better able to appreciate the vastness of the object, and I became more and more impressed with the grandeur and sublimity of the scene up to the last moment of my stay. I was

the most impressed with the power of the falls at the bottom of the American falls; but I think the best view is obtained from Table rock. I have read perhaps a dozen minute descriptions of Niagara falls, but I had a very faint notion of the scene until I visited the spot. Words are insufficient to convey a just idea of the falls.

From Niagara there is a railroad to Lockport connecting with the canal at the latter place, and also a branch to Lewiston, whence a steamer runs daily down lake Ontario, touching at Oswego: I took the latter route. Lewiston is but a small village seven miles from the falls: directly opposite is Queenstown, which is only remarkable for the desperate battle which was fought there and the monument to Gen. Brock, which crowns the hill above the town.

At the entrance into lake Ontario on the Canadian side, is the town of Chippewa, celebrated also for a bloody battle. It is very beautifully situated, but does not appear to be a place of great business. Fort George occupies the point below. On the opposite side Fort Niagara frowns defiance. The latter spot is notorious for the Morgan tragedy, which has caused so much excitement in the political world. The passage down the lake was very pleasant: there are many clearings along the shore showing a great many fine farms and several very pretty villages.

We breakfasted the next morning at Oswego, and took the stage for Syracuse, our company preferring that conveyance to the canal.

The land in this section of the country is hilly and quite stony, but the soil is productive in grain and grass, and fruit trees thrive very well.

Our route was near the Oswego canal, passing through the villages of Fulton, Phenix and Liverpool. At the latter place I made a hasty examination of the salt works. The water is obtained from a spring discovered by boring in Onondaga lake, 30 rods from the shore. The water is said to be eight per cent. stronger than that of Salina. The salt houses are all similar: they have forty kettles set in a double row, and I was told that from 200 to 250 bushels per day were made in each house.

The salt works at Syracuse and Salina are supplied from a natural well in Salina. The salt houses are very numerous, and besides these there are two fields of 60 acres each, where salt is made by solar evaporation. I could not learn exactly the quantity of salt made at these three places; but it is much greater than I had supposed, and it is of very good quality;—that which is made by solar evaporation, however, is much the best.

Syracuse has had a very rapid growth and has become a very important place and is still increasing. Its situation for business is equal to any inland town in the country. I spent two days in the vicinity of Syracuse, and was very much pleased with the country around it.

I left Syracuse at 4 o'clock in the afternoon in the cars and arrived at Utica 52 miles, a little after dark, and at daybreak the next morning we were at Schenectady, 90 miles further—and as soon as we could exchange cars we were off for Albany, where

we arrived at 6 o'clock. At 7 we left Albany for New York. The passage down the river is very pleasant: Hudson, Catskill, Poughkeepsie, West Point, &c. are places of interest, and the highlands and palisades afford much grand and picturesque scenery. We arrived at New York at 9 minutes past 4, having made the quickest passage on record from Albany to New York. At 5 o'clock I left New York, and at 7 the next morning I was at my own house, having travelled since I left home about 4000 miles, and the last 600 of it in 39 hours, including stops.

GENERAL VIEWS OF THE WESTERN COUNTRY.

Those who have read the foregoing pages will perceive that I have travelled through some of the most important portions of our country, and having travelled much with men who are extensively acquainted with other portions of the country, I have received the benefit of their observations and comparisons upon the spot, and I will now give some general remarks with regard to the soil, climate, agriculture, population, &c., and the conclusions which I have drawn, in the hope that it may be useful to some of my readers and save many from the trouble and sacrifice consequent to an ill-advised removal of their families, with false hopes and under circumstances which render such a removal extremely unwise and in a majority of cases unfortunate.

Travelling from the Atlantic coasts westward, the country is divided into three great divisions, which are plainly distinguished from each other by their natural features. The first is that part of the country which lies east of the Alleghany mountains, and may be called the Atlantic country, or the east; the second embraces all the country west of the mountains and east of the Wabash river and a line drawn from that river to the west end of lake Erie, and may be termed the middle or forest country; and the third embraces all beyond the Wabash, even to the Rocky mountains, and may be called the prairie country, or the far west.

The first division is distinguished by the unevenness of the surface, being broken into hills and valleys, and generally possesses a hard, rocky soil. This is the country for romantic views and picturesque scenery, and better adapted for a grazing, than a grain growing country, though there are tracts in this division, equal at least, to the most fertile districts in our whole country: these tracts are found in the eastern part of Maine, the valley of the Connecticut river, a tract about thirty miles wide west of Albany, reaching nearly to lake Erie, and a large tract lying in the central and southern portions of Pennsylvania; and there may be other tracts of small extent of equal fertility, but as this division has become an old and well settled country, and is generally well known, I shall say little more about it except for the purpose of comparison.

After crossing the Alleghanies we descend into the great valley of the Mississippi and its tributaries. Western Pennsylvania and the eastern part of Ohio are hilly, but the hills are smooth and

rounded, and of small elevation compared with the hills of the east, and they diminish in height until they become only gentle swells, or what is called rolling, and the north west corner of Ohio, and the central and southern parts of Indiana, are flat and level, or nearly so.

(Continued on page 436.)

From the Farmer's Cabinet.

HAYMAKING.

Sir,—As the season for haymaking is near at hand, I feel desirous of bringing your numerous readers acquainted with a *practice*, that is based on so true a *theory*, that—as ought always to be the case—they go hand in hand to the end of the chapter. As so much of the happiness of the farmer depends on the stock of hay which he can prepare for his winter consumption, any information, tending to facilitate the process, and at the same time lessen the labor and expense and hazard of the business, I consider of great importance. The following observations, reflections and instructions, are therefore presented to their notice, by their friend and well-wisher,

JONAH CORBIT.

N. J., May, 1840.

“Having observed, that in a season where there was no rain whatever, and the hay had been made with rapidity, and carried within a short time after it had been cut, that a greater quantity had been injured by being over-heated and burnt, than in a catching irregular season; that when hay had not heated in the stack, it was frequently mouldy; that as hay lost its native green color and approached a brown, it lost its nutritive qualities; and that, altogether, the making of hay, as usually conducted, was a very precarious and troublesome operation:—I determined on trying to arrange a system on more regular and certain principles, and in which I succeeded—and by adopting a certain and regular course of operations, was enabled to make my hay of a uniform good quality; and, let the weather be as it might, at a pretty regular expense for labor, and considering such a process not only of importance, as it insures a more perfect quality, but as it affords a more certain protection against the injuries usually consequent on the uncertainty of the weather, and over-heating in the stack, and that it thus removes two great causes of anxiety, it may be well worth the public attention.

In the first place, then, as to the state of the weather—it generally happens at this season of the year, that there are three or four rainy and three or four dry days, [in England.]—therefore, on beginning to cut the grass, as it is well known the grass may be cut and suffered to remain in the swarth for several days without injury, and it being desirable where hands are plenty to have a good quantity or as much as will complete a stack in a day, in the same state of forwardness, I should prefer, rather than to wait for fine weather, to begin to cut in rainy weather. However, be this as it may, the swarths should not be opened but on a fine day, and when this is done, the grass should be well shaken apart and equally spread over the ground—and as soon as the upper surface is dry, turn it well over, and in this operation great care should be taken to open and spread any cocks that may not have been divided in the first opening: this being done, commence raking into wind-rows in time,

that the whole may be made into small cocks before night. *The second day these cocks must remain untouched, let the weather be wet or dry.* The third day, if the weather be certain and fine, throw the cocks open; but if the weather be wet or threatening, they may remain another day, or until it is certain to be fine for the day. The cocks should then be thrown, according to the crop, into beds of two or three rows, and after three or four hours' exposure, turned over, and taking time to gather the whole into wind-rows and cocks before night—let this operation commence accordingly, and *none be left open.* The day after this, which in fine weather will be the fourth, the *cocks must again remain untouched, or not be opened, whether the weather be wet or dry.* On the fifth, or the next dry day, these cocks will only require to be opened for an hour or two, after which time they will be fit for the stack.

The novelty of this mode, consists only in suffering the hay to remain in cock the second, third or alternate days; and at first sight it may appear that so much time in fine weather must be lost, but this is by no means the case, for whilst the hay remains in cocks, a slight fermentation, or what is termed sweating, will take place; and in consequence, after it has been opened on the third and fifth days, it will prove to be just as forward as if it had been worked every day; and the advantages resulting from this are obviously the following:

By shortening the time of open exposure, the color of the hay is more perfectly preserved, and consequently, the quality—and the fermentation or sweating which takes place in the cocks, proves so much to have diminished the principle or inclination, as to prevent its heating injuriously in the stack—and the whole operation of making, whether it takes four days or eight, requires three days' labor only; and the hay being left in that state every night, in which it is the least possibly exposed to the injuries of the weather, and in which it may remain for a day or two in uncertain weather, without injurious exposure, most painful anxiety and useless attendance of labors are obviated.”—*Hayward Science of Agriculture.*

From the Albany Cultivator.

LIME.

“Were lime a manure, it would be a noble substance for enriching and restoring fertility to lands worn out by a succession of crops; but, as worn out land is not restored to fertility by the application of lime, we are warranted to consider it in a different light; or, in other words, as an article to bring certain principles into action, previously possessed by the soil. This conclusion is sanctioned by experience; and experience is a far better guide than the most plausible theory.”—*Morton on Soils.*

We think this short extract has, in very few words, set right a matter of great importance to the farmer, and corrected an error which is prevalent, not only in Great Britain, but also to a considerable extent, in this country, viz: that lime will restore to fertility all lands that have been exhausted by cropping. But lime is not a manure, in the sense in which animal and vegetable matter is—it is not nutritive itself, it only assists in nutrition; and however important the part it acts in this way, unless nutritive matter is existing in the soil, ready

to be appropriated to the use of plants, the application of lime is entirely useless, so far as the restoration to fertility is concerned. Every one can see, that when all the vegetable and animal matter has been exhausted in a soil, by ceaseless cropping, and nothing but the primitive earths, silice, alumine, lime, magnesia, &c. of which it is composed, remaining, that the application of more of any one of these primitive earths, will add nothing to its fertility or capability of producing vegetation.

If, on the contrary, there is vegetable or nutritive matter in the soil, lying dormant for want of exciting agents, or in an insoluble state, and therefore inaccessible to vegetation, an application of lime by removing one or both the causes, may render the most essential aid to the farmer, in the production of his crops. A neglect of this important fact has led to serious error in the use of lime in England, and in this country. Because, in some cases lime has produced the best effects, it was at once expected in all; and, because, where nutritive matter existed to be called into action by the lime, a great increase of the crops were the result, it was supposed that this effect could be renewed at pleasure; and liming without manuring, became at once the order of the day. As must have been expected, a failure in the crops, in such cases, has been the result; and a prejudice against the use of lime, resulting from its application on false principles, has succeeded the most unbounded confidence in its favor.

Lime is a noble substance—it cannot be dispensed with in soils, but like the other earths it is powerless alone. The man who eats curry or cayenne with his roast beef, does not expect his nourishment from them—they are only the accessories, the stimulating agents. The farmer who has just views on the subject of vegetable nutrition, does not expect his plants to subsist on the lime, salt or gypsum he furnishes them; nor does he expect that these stimulants of them, without the application, in some form, of vegetable or animal matter of which the plants can avail themselves, will restore fertility to exhausted soils, or continue it in such as now possess it. No farmer should forget that no single substance can ensure fertility; not one of the earths or one of the stimulating or nutritive manures, can do this; the presence of all is necessary—and the best proportions ensure the greatest productiveness in any soil.

JERUSALEM ARTICHOKE.—Some experiments with this common root are on record, which would seem to show that, with proper management, it might be made valuable in cultivation, particularly as a winter food for store hogs. Once introduced into a piece of light rich ground, it is not eradicated without considerable difficulty, as all those who have planted it in their gardens are aware. In the kitchen garden, the artichoke should always have a place, as the fresh roots in the spring, gathered and sliced thin and eaten with vinegar, are relished by most people—and they make a very good article for pickling. If intended for swine, they should be planted at least two years before the swine are turned into them—after which, the annual rooting of the swine will be all the cultivation or stirring of the earth that will be required. The smallest pieces are sure to grow, which renders their propagation as easy as their extirpation is difficult.—*Albany Cultivator.*

From the Maine Farmer.

SIGNS OF THE TIMES.

Although we have put a political caption to the head of this article—or rather, one which politicians love to use, we are not about to enter the battle ground of either of the contending parties as they are at present organized. We wish, however, to call the attention of the friends of our own country to some of the signs now rising in the distant horizon, which indicate that before many years there will be a change in the existing tariff, and that those who live south of Mason and Dixon's line, and who so bitterly opposed that portion of the tariff which afforded encouragement to Northern Manufacturers and Northern Wool Growers, even to threatening a dissolution of the Union, will ere long change positions and beg right heartily for such an alteration as shall also protect them—aye protect them in their own staple products, viz: cotton, tobacco, and hereafter, silk. And we much mistake if they will not then be willing to shake hands with their brethren of the North, and unite in forming such a schedule of duties as shall be mutually beneficial to all sections of the Union. This is what they ought to have done before—this is what nature itself points out should be done. The two extremes of our country, embracing as it does, such an extent of territory—stretching through such a variety of climate, and well adapted to supply the wants of each other, one would suppose that it would be an object for each to study the other's welfare in accommodating each other. The North is well adapted to the growth of wool, lumber, hay, oats, and to manufacturing. The South to the production of cotton, rice, silk, sugar, &c. Why not then arrange our tariff that each branch shall be encouraged? But the South, by their opposition to the North, have virtually said, we care nothing about you—we had rather trade with Europe—she will accommodate us on most any terms—and we are not going to assist in building you up when our mother country is so kind to us. So off with your duties upon woolsens, &c., or we will blow up the Union. England, too, when she saw that she could accomplish two objects with one act, namely, sow dissension among us and have our duties reduced, sung cherily the siren song of free trade to us, but at the same time shut her own ports to the whole world, except in such cases and in such times as it would be for her own particular benefit to open them or change her restrictions. So, to keep the peace among ourselves, the duties on woolsens, &c., were reduced—little or no duty put upon silks, and some other articles. But to the signs, what are they? We see, by the American Farmer, that there is to be a grand convention of tobacco growers in Washington city this month. What is the matter? Why, it is found that this article, which is now an immense article of trade throughout the world, is restricted in some countries. France, for instance, prefers to encourage her own people in this business, to the great detriment of the growers of the U. States; and while we have been so good natured as to admit her silk almost duty free—she has been so ill natured as to hamper our tobacco trade in such a way, as to give her own people the monopoly. And the Southerners begin to think that it will be best to shut down the gates upon their silks, unless they will change their course in regard to tobacco. Besides, the

culture of silk is coming into vogue in the South, and may be made so extensive as to put Europe in the shade, if it could be encouraged, or the French and other silks kept back.

Again, England is waking up to the culture of cotton in her East India possessions. She has sent an agent into this country and has engaged nine practical cotton planters to go and take charge of as many plantations in India. They are to have a salary of twelve hundred pounds per annum each. Native laborers can be employed to any extent in India for two dollars per month. Great Britain has appropriated twelve thousand pounds to push forward the enterprise, and it will not be long before the Northern manufacturer can obtain his cotton from India, cheaper than from Georgia or Alabama. In addition to this, Texas will be pouring it into the market also. Will not the Southern planter cry out for a prohibitory duty on cotton? We have no doubt of it—and for one we should be willing to give it, provided they would also consent to such an arrangement that all sections could be mutually encouraged in the crops and manufactures peculiar to their climate and situation.

Our farmers, who control the ballot-box, must, by judicious legislation, provide a stable home market for the products of their industry. We beseech them to weigh well the fact, that there was brought into the United States and sold, no less than one hundred and fifty-seven millions' worth of foreign goods in the year 1830. And in this connection, remember that the duty on American flour in English ports, on the 15th of April, 1840, was two dollars and fifty cents per barrel. This is more than the flour is worth in the wheat growing sections of Ohio, Michigan, Indiana, and Illinois. Shall our own agricultural interest have no countervailing protection? We imported, last year, twentyone millions of silks, duty free. Suppose, instead of sending twentyone millions of specie, or its equivalent, to pay for these silks, we had manufactured that amount more of goods at home, at least ten millions of provisions, in one shape and another, would have been consumed in the operation; and all the profits of the manufacturers, the producers of the raw material, mechanic labor, and the food consumed by all, would have enriched our own citizens.

Our mechanics, such as shoemakers, blacksmiths, carpenters, tailors, and the like, have a deep interest in the encouragement and protection of domestic manufactures. Indeed their interests are the same with nearly all other classes, who must depend on the productive industry of the country for their own individual prosperity.—Hence, the great national importance of encouraging, by all suitable means, every man, woman, and child, to be both industrious and economical. Hence our republican family should not so disgrace themselves as to maddly run into debt to Europe 147 millions a year, for worthless aristocratic finery, and then have one half of the property in the Union sold under the hammer to foot the bill. All sensible men should insist on an effectual protective tariff, that shall cut off this disastrous extravagance. If the rich will have one hundred millions worth of silks, wines and the like, from abroad, let them pay into the national treasury at least forty millions, which can be well expended as a common school fund, as has been done with the surplus belonging to the State of New York. This will be a tax upon luxury for the benefit of education, general science, and intelligence.

From the New Genesee Farmer.

Messrs Editors—I saw a statement in your last number, of an ox that was taken sick and died, supposed from the horn disease. Now, I am not a farmer nor a farrier's son, but I learned forty years since how to cure the horn distemper, and can do it without risk or failure if applied to in season. I have cured them when fat, and past standing, and in winter when they were poor. You will easily discover when it is the horn ail, by their dull sunken, dry nose, cold horns, and refusing to eat.

The following is my remedy:—Take half a table spoonful each of spirits of turpentine, camphor, fine salt, and black pepper made fine, and one gill of sharp vinegar. Mix them together, warm them to a blood heat, turn the animal's head so that the ear will be uppermost—take hold of the ear and put in as much as you can, hold it tight, and pull it up several times; then serve the other the same—do it once a day for three or four days—split the tail if necessary—and the cure will be effected. There is no mistake about it. A. DIBBLE.

Byron, Genesee co., N. Y.

From the same.

THE CURCULO.

The fruit-garden is a delightful promenade in summer and autumn; but too many freeholders forget all about it in the planting season. Where the enclosure is large, plums, apricots, and nectarines, ought to stand in a quarter by themselves, so that the hogs may be confined among them at the time when the Curculio is most active. This suggestion had not occurred to us when we planted our fruit-garden; and the benefits to be derived from the presence of the hogs, are in some measure, lost. As a remedy, however, we have fed screening and other small grains, under some of those trees; and a few days ago we went to ascertain the result. A sheet was first spread under several trees in a remote part of the garden which had received no attention, and from these we got more than twenty of these insects; but not a solitary one was caught where the hogs had trodden the ground hard.

Since that time we have frequently gone into the fruit-garden with a basket of grain in one hand, and a mallet in the other, the whole drove of hogs following. Having jarred the tree with the mallet, by striking against the stump of a limb cut off for the purpose, we strewed the contents of the basket without delay. This insect is timid, and its danger in lying on the ground at this juncture is not merely ideal, for a fearful trampling succeeds; and if it should not be instantly crushed, we hope it will not soon return to the spot. †

Stirring the ground.—Nothing conduces more to the growth of crops than frequent stirring of the ground; especially is this necessary in dry weather, and where the soil is inclined to bake or become hard. Ground which is frequently stirred in dry weather, will be found moist, while that which is not stirred, will become perfectly dry. We say then, stir often, use the hoc, rake, cultivator, whatever you please, but if you want great crops be sure and keep stirring.—Genesee Fur

From the Journal of the English Agricultural Society.

ON THE USE OF SALTPETRE AS MANURE.

BY GEORGE KIMBERLEY, ESQ.

To take a retrospective view of the use of saltpetre (or nitrate of potash) as a manure, may well at the present day be considered superfluous, but it may not be amiss to remind the reader that saltpetre was known and used as long since as the time of Virgil, and we find a notice or hint of the effects of nitre or nitrous water worth the attention of farmers in the *Sylva* of Bacon, published in the year 1670. Evelyn also understood some of the advantages of saltpetre as a manure: it has also been tried and reported on by various authors down to the year 1828, when, in No. 3 of the Quarterly Journal of Agriculture we find an account of its use by William Hawkins, Esq., of Hitchin, Hertfordshire, where the experiments appear very satisfactory and conclusive. Since that time, though the use of saltpetre has been partially continued, yet it may be said, considering its value, that it has been much neglected; nor does it ever appear to have been established as a standard auxiliary manure. Mr Cuthbert Johnson justly observes, "that the agricultural uses of saltpetre have not been examined so carefully or generally as they ought to have been." The neglect of so valuable a fertiliser when there are thousands of acres requiring such assistance, is most extraordinary, and attempts have been made by different authors to account for it. One supposes that the price may have been an obstacle; another that it was not obtained pure, and therefore the experiments failed. But my observations on the use of artificial manures generally lead me to other conclusions, and I think the history of saltpetre furnishes us with the history of nearly all artificial, but particularly saline manures, the use of which, I regret to observe, has been successively and hastily adopted, without reference in many cases to season, soil, climate, or quantity; and as a few fortunate experiments have started into a fashion the use of these articles, so one or two unseasonable or improper applications has at once condemned them to neglect and oblivion; and though from the advancement of science I should now hope for some satisfactory result from the trial of that class of fertilisers, I fear that the indiscriminate use to which I daily see and hear of their being applied will again end in their expulsion from that rank in which they ought to stand, as great and useful auxiliaries to our stock of known manures. It is not my intention to make a compilation from the various authors who have written on saltpetre, but as all persons may not have seen the article above mentioned in the Quarterly Journal, I may, I hope, be excused for extracting so much of the report as will give some weight to my own opinions, and direct the attention of the public to so important a statement. It there appears that Lord Dacre and 10 other gentlemen and farmers have used saltpetre for different periods, varying from 15 to 3 years, on almost all sorts of crops, and though there are some differences of opinion as to its merits as a manure for wheat, yet the whole of the report may be considered as conclusive of the value of saltpetre as a top dressing; but I beg to refer gentlemen to the report itself, which will be found as above mentioned.

Now, as to my own experience, it was in the

year 1827 that I first used saltpetre in any quantity, and as it is my constant practice to try every artificial manure by some standard of known value, I manured part of 14 acres of seeds in the autumn of 1826 with 10 cart loads of good dung per acre, leaving a portion in the centre of the field to be dressed with saltpetre in the following spring. The decomposition of the dung, and the protection it had afforded during the winter, caused the clover thus manured to be very rank and forward in growth, and far superior to the unmanured part, which looked weak and bare. I however waited till the clover had just begun to grow, and then, after having reduced the saltpetre to a fine powder it was sown by hand on the land left for that purpose. In about a fortnight from that time I went to examine it, and could see distinctly where the saltpetre had been used: it already surpassed the part manured with horse-dung in the breadth of its leaves, and richness of its color, which was changed to a very dark green, and it continued through the season to grow with a luxuriance of vegetation that produced a very large crop of clover, quite equal, if not superior, to that of horse manure; nor could we distinguish any difference in the value in the succeeding crop of wheat. The saltpetre was used at the rate of 1 cwt. per acre; cost, 26s. 6d. in London; carriage and sowing included, about 2s. per acre. The horse manure from the farmyard, 10 loads, or 25 yards, at 4s. per yard; cartage, 10s.; spreading, 2s. making a total of 5l. 12s. per acre. The expense would have been much increased had not the field been near the farm. The trial was on sandy land of moderate quality. I could add a great number more experiments, which would be but a repetition of the above, and I have used it on spring corn with equal success. I also recommended it to a friend who tried it on oats, barley, and grass, and a few weeks after the application I had an opportunity of inspecting the crops, which were considerably higher and of a much darker green where the saltpetre had been used than the other parts of the fields, and were judged to contain from 8 to 12 bushels of corn more per acre. Its effects were equally striking on the meadow. It was used at 1 cwt. per acre.

Nitrate of potash, according to Thomson, consists of

1 atom of Nitric Acid	6.75
1 atom of Potash	6.00

—

Or (in 100 parts) Nitric Acid	54.34 parts
Potash	45.66

And it is said by Davy to contain 1 part of Azote, 6 of Oxygen, and 1 of Potassium.

It would be presumption were I to venture an opinion on its mode of operation, nor for our present purpose may it be necessary; a well authenticated collection of practical facts are of more service and better understood by agriculturists. It may be asked, Do you use saltpetre now? to which I answer, Yes, and, while I require manure, probably always shall use it, but not by itself. I consider saltpetre to be a necessary constituent and valuable component part of all manures. I can safely recommend its use alone as a top-dressing on all crops, (except wheat which I have not tried)*

* When tried as a top dressing on wheat, it has been found to increase the bulk of straw; but in many cases to occasion mildew.

clover and all trefoils particularly, and, as far as my experience goes, as to the best method and time of application, I think it should be finely pulverised and sown with care and regularity on corn or grass, at the rate of 1 cwt. to 1 1-4 cwt. per acre, just when the crops begin to feel the influence of spring, and vegetation is making its first efforts. Its effects then, particularly if the weather is favorable, are as sudden as they are gratifying, and the rapid change in the color and growth of the crop gives ample and satisfactory proof of its almost miraculous powers.

GEORGE KIMBERLEY.

Trotsworth, Surrey, Nov. 18th, 1839.

From the Third Report on the Agriculture of Massachusetts.

ON PLOUGHING IN CROPS FOR MANURE.

Boston, March 25, 1840.

DR S. L. DANA—DEAR SIR—Two successful and experienced farmers, one in Franklin and one in Berkshire county, have come to the conclusion that, in turning in crops by way of enriching the land, more benefit is derived, that is, the fertility of the land is more advanced by ploughing in a crop after it has become dried or dead, than by turning it in its greatest luxuriance and greenness. One of them showed me the results of an experiment tending to this point, which appeared strongly to favor his conclusions. A well-established fact is better than the most elaborate hypothesis; and prejudices, however strong, must yield to facts.

Allow me under these circumstances to inquire whether, upon your principles or philosophy of vegetation, there occur to you any good reasons for a result so much at variance with popular opinion. Your views in full on this subject, will add to the obligations under which you have already laid the public and your respectful friend and servant,

HENRY COLMAN.

Lowell, March 28, 1840.

DEAR SIR—The results referred to in your letter are opposed to the common opinion. Common opinion, especially in agriculture, is not always founded on observation. It is oftener prejudice, than opinion; and when inconsistent with well known facts, has not its source in observation or experiment. The whole resolves itself into this, *dry plants give more grain than green.* This follows from the little we know of the process termed "fermentation;" I use the term as commonly expressive of the spontaneous decay of vegetables. It includes the three stages of vinous, acid and putrefactive fermentation. These are not necessarily dependent, following in regular progression. They are not cause and effect. Putrefaction may commence first, and it is so different from the other two, in all its stages and products, that the term "fermentation" ought never to have been applied to it. The greater part of vegetables are susceptible of putrefaction only; a small number become acid at once, and a still smaller number ever undergo vinous, acetous, and putrefactive fermentation. Fermentation then, in its widest sense, will help us to understand how dry crops may be better manures than green. Let us glance at the principles and products of fermentation.

1st. What vegetable substances are susceptible of the vinous fermentation, and what are its products?

The juices only which contain sugar or starch,

convertible first into gum and then into sugar by the action of azotized vegetable principles, especially gluten. Pure sugar never ferments. The vinous fermentation must be excited by some substance containing nitrogen. There are three things essential to vinous fermentation—air or oxygen gas, moisture in due proportion, and a temperature never below 50° F., nor above 86° F. The products of this process are gases, ferment, or yeast, and vinous liquor. The gases are carbonic acid and hydrogen: the yeast proceeds from a change in the organization of the gluten and albumen; some late French experimenters think it proceeds from a continued evolution of infusorial plants; hence yeast begets yeast, like sowing crops of seed. However, let us leave speculation. The main facts are as above stated. If, then, we plough in green plants, we put them in a temperature favorable to the commencement of vinous fermentation; we bury them full of sap—the requisite moisture for vinous fermentation,—we cover them whilst their saccharine principle is in its perfection. Every thing favors vinous fermentation. The sugar and starch of the plant fermented by its gluten and albumen, are converted into gases and alcohol; the former are lost in air, the last washes away or is changed to vinegar. All that remains for the farmer is the altered gluten and albumen, which soon putrefy and form geine. All the starch and sugar of the plant are thus lost.

2d. What vegetable substances are susceptible of the acid fermentation, and what are its products?

The substances are, first, sugar, which in certain cases becomes acid, without undergoing vinous fermentation; second, gum. The circumstances essential to acid fermentation are air, moisture, and a temperature from 65° to 70° F.; acetic acid is itself the proper ferment of acid fermentation. Vinegar, as is well known, singularly promotes the formation of vinegar in vinous liquors. The products are, carbonic acid, acetic acid or vinegar, and some other acids, especially that called nancic or zomic acid, which if not lactic, is perhaps only acetic acid, holding in combination some azotized substance. This acid combines with the alkaline and earthy ingredients of plants and soils, and forms very soluble salts. Green plants, ploughed in, are at once placed in a situation most favorable for undergoing acid fermentation. We suffer a loss of a part of the carbon, and in addition to the sugar and starch we now lose the gum of the plants. All these are capable of producing geine, and hence in ploughing in green crops, we lose a portion of manure.

3d. What are the vegetable substances susceptible of putrefaction, and what are its products?

With the exception of oils, resins, &c., every organized part of every vegetable may putrefy. The circumstances essential to this process, are air, a temperature not below 45°, and moisture. No perfectly dry plant ever putrefies, nor will a moist one, if air is excluded. I have had a capital example of the last, in a piece of a white birch tree, dug up from a depth of twentyfive feet below the surface in Lowell, this winter. It must have been inhumed there probably before the creation of man, at least at a time "whereof the memory of man runneth not to the contrary," yet this most perishable of all wood is nearly as sound as if cut from the forest last fall. A dried plant has parted with most of its sap, that moisture essential to the commencement of vinous and acetous fermentation. During the very act of decay, from the moment when its living functions have ceased, new combi-

nations of its elements begin. It has already begun to be destroyed by the very agents which gave it life. This is the beginning of putrefaction. Let us not be deceived by a name. Putrefaction we always associate with disgusting effluvia. But in the wide sense we have defined it, it includes also the fragrance of new hay. Whenever bodies consist only of oxygen, hydrogen, carbon, and a trace of azote, their putrefaction is fragrant or inodorous; when, in addition to these, bodies contain large portions of azotized matter, gluten, albumen, or sulphur, and phosphorus, putrefaction evolves abominable odors. To the agriculturist, putrefaction is always a wholesome process, beneficial to his best interests when promoted and controlled. There is only one case where this process produces loss:—this may be termed *destructive* putrefaction: it is produced by heaping together green plants, or sometimes by moistening dry vegetable substances. Here oxygen is rapidly absorbed, and finally the mass takes fire and burns. Up to the moment of inflammation this is putrefaction. New hay, stacked too green, is a familiar example. Volumes of steam are evolved, which proceed partly from the decomposition of the plant; decompositions and recompositions rapidly ensue; these are the ferment, which keeps up the action till the plants burn.—Doubtless all green plants ploughed in, undergo to a greater or less extent destructive putrefaction, which succeeds the vinous and acid fermentations, perhaps caused by the very rapidity of these processes. Hence, in addition to the sugar, starch, and gum of the plant, we lose a large portion of its other substances, by turning it in green. The products of this rapid fermentation have been but little studied. Happy the farmer who never witnesses the process. He should never induce it, and may generally prevent its extension when once begun. It is a dead loss to him; but in all other cases of putrefaction the products are valuable:—these vary according as the process takes place: 1st, in air; 2d, at the surface of the ground; or, 3d, deep in the interior of the earth. The last need not detain us—it produces all the varieties of coal.

1st. In the free air, having access to all parts of a plant, putrefaction produces carbonic acid, nitric acid, and water. But ordinarily, in the air, as oxygen does not find ready access to all parts, a portion of the hydrogen of the plant combines then with the carbon, sulphur, phosphorus and azote of the plant, and we have carburetted, sulphuretted, and phosphuretted hydrogen, and ammonia produced. Now, as these exist but in small quantity in vegetables, the loss of hydrogen will not be very great by drying the plants, and it is possible that the removal of these may cause the other elements to enter into more stable combinations, better fitted to produce geine.

In all cases of putrefaction in the open air, oxygen is absorbed, and an equal bulk of carbonic acid given out, while, at the same time, the oxygen and hydrogen of the plant escape as water. The result is, that in the substance left, carbon exists in a greater portion, than in an equal weight of fresh vegetables. In all cases of putrefaction, new products are formed; these again resolve into others; and this action goes on till we have no longer any organic products; we have only binary or inorganic substances left. All our researches into the philosophy of the changes in fermentation, terminate in these binary products, that is, in compounds consisting of only two elements. During all these

various changes, a variety of substances must, of course, be formed. As the elements of living, and the elements of dead plants, are continually changing into new forms.

Nature is admirably simple, and never so learned as our books. We ought not to dignify with a new name, every new product of putrefaction, which we may fortunately arrest. However various these products may be, whether products or educts of putrefaction, or of our analytical methods of separating them, all putrefaction at the surface of the earth, ends by forming a brownish, black, powdery mass, which combines with the alkaline, earthy and metallic basis in the plant. This substance has been called "Geine." As I have elsewhere defined it, it is decomposed organic matter of soil. It is the product of putrefaction—continually subjected to air and moisture, it is finally wholly dissipated in air, leaving only the inorganic bases of the plant, with which it once combined.

Now, whether we consider this as a simple substance, or composed of several others, called crenic, apocrenic, putanic, ulnic acids, glairin, apothenic, extract, humus, or mould, agriculture ever has, and probably ever will consider it one and the same thing requiring always similar treatment to produce it; similar treatment to render it soluble when produced; similar treatment to render it an effectual manure. It is the end of all compost heaps to produce soluble geine, no matter how compound our chemistry may teach this substance to be.

Among the many economical modes of producing geine, the ploughing in of vegetable matter, has held a high rank. Nature teaches us to turn in the dried plant. Dried leaves are her favorite morsels, and the very fact, that Nature always takes the dried plant, from which to prepare the food of growing vegetables, should have taught us long ago, the wisdom of ploughing in dry crops. The careful collecting and husbanding of dried leaves, their superior efficacy in forming compost, bears witness to the facts stated in your letter. That the use of dried leaves for compost, has not led to the turning in of dry crops, has probably arisen from the consideration, that a greater quantity of geine may be produced, by turning in two or three green crops in a season, than by one crop of dry. This needs experimental confirmation. The very act of tillage, on Mr Keely's plan, by exposing the insoluble geine of one crop to air, renders it soluble, while at the same time, two or three green crops must form a greater quantity of salts. If only one crop can be turned in, let it be dry. All our philosophy, and the late experiments of your agricultural friend, confirm this view.

With great respect,

I am very truly yours,

SAM'L L. DANA.

REV. H. COLMAN,

Agricultural Commissioner.

WEEDS.—Some persons pretend to believe that weeds are an advantage as a shade to young crops in dry weather; but this is a great error and only a subterfuge for indolence. It is well known that weeds rapidly absorb the moisture and nutriment from the soil; and on examining beneath the surface in dry weather it will be found that the ground is much drier where covered with weeds than where kept clean. They deserve no protection from the farmer, and should be destroyed while young.—*Genesee Far.*

NEW ENGLAND FARMER,

AND HORTICULTURAL REGISTER.

BOSTON, WEDNESDAY, JULY 1, 1840.

EXPERIMENT WITH MARSH MUD.

To the Editor of the New England Farmer :

If not quite agreeable to one's own feelings to detail experiments not altogether successful, yet it may be of considerable advantage to others. Influenced by this consideration, I will proceed to give you an account good and evil, of an experiment with *marsh mud*.

In 1838 I procured nearly forty tons of this and had it brought to my place, some twelve or fourteen miles from the ocean. A part of it was put in holes as a manure for potatoes, on land ploughed that spring, and which had for several years been used as pasture, the soil being a mixture of sandy and slaty loam, of middling quality; and a part on a small piece in another field of gravelly loam; and from a comparison of the crops raised on these pieces with those in other parts of the same fields where common manure was used, and with the crops in the vicinity both in quantity and quality, I think the benefit was obvious. Most potatoes in this vicinity that year were of a poor quality and much injured by worms. That portion of mine manured with this mud were unaffected by worms, came out with smooth skins, when cooked neatly, of a pleasant taste, and the yield good.

Another portion of the mud was spread upon land cultivated with Indian wheat. This crop was not certainly benefited by it. The soil of this lot is a sandy loam, mostly diluvial and rather dry.

Some of it was used by a person who hired a piece of land to cultivate. He tried it in the hills with corn; most of the corn failed to come up; but he thought that what did come up was helped by the application. The corn was of good color and stout.

A part was applied to land cultivated with beets, carrots, parsnips, onions, &c., all of which, but especially the onions, (the greater part of which were what is called the potato onion,) were very evidently improved by it in quantity and quality.

In 1839 I planted one of the fields again with potatoes; the crop was good, and being without question improved by the mud applied the year before.

The other parts of the fields where the mud had been used were also in 1839 planted with corn; and from various considerations which it cannot be important to state, it is rendered certain that the yield was considerably less than it would have been had none of this article been spread upon the land. One circumstance, however, I will mention: a part of the mud was kept in a pile the first year; was often and well worked over, and mixed in part with some earth and a quantity of lime, and I believe a little ashes. Some of this was put in holes with the corn, and planted where the Indian wheat was cultivated the year before. In this part of the field the corn came up very badly, grew very slow and remained extremely small through the year, very little if any of it getting to be over two feet high, slender in proportion, and the ears very small, where there were any. White beans were planted in the hills where the corn failed to come up, but these flourished no better.

This year the fields are sown mostly with wheat, barley, oats and millet: those parts where the mud was used in the largest quantity are occupied mostly with wheat; and it is very apparent that just about in proportion to the quantity of the mud is the unpromising state of the wheat. The stocks are small and sickly in their appearance, while the leaves die at the upper ends and sides, resembling in many particulars a field parch-

ed up with excessive drought. The effect upon the other grains is not yet so obvious, and indeed from the parts of the ground which they occupy, it will not be easy in the end to determine with so much clearness how far they may be helped or injured by this (to me) experimental manure.

In my vegetable garden I continue to have satisfactory evidence of its beneficial effect.

I am aware, Mr Editor, that these experiments have not been made in a very philosophical or farmer-like manner, and therefore the results should not be allowed to have great influence upon the opinions and practices of others; and yet from their extent and the time occupied by them, they may be regarded as entitled to some consideration; and if they should be instrumental in helping any brother farmers to raise larger crops of some kinds and save them from partial losses in others, the object of giving an account of them will be answered, and a small return be made for the many helps I have received from your highly interesting and useful publication, by the many *successful* experiments brought before the public. B.

P. S.—Since writing this I have heard it observed that the very neighbor who commenced a trial of the mud about the time I did, sustained a similar failure in his corn to that which I have mentioned, and that having laid down his fields to grass, is likely to realise a most entire failure in the crop this year: the grass (timothy) being very small, of sickly appearance, and the leaves all turning black at the ends and sides. How his experiments have resulted in other crops, I am not able to state.

EVERY THING IN ITS ORDER.

Oxen and horses can do a great deal of work in a year without much inconvenience, if they are wisely and kindly treated. I am not about to give a full lecture on the subject of their treatment: my remarks are intended to apply to a single point, which is that they should not be kept unnecessarily for any time in harness. My attention was directed to this subject by an incident which fell under my observation some time since. A farmer whose conduct fell under my observation, observed in his sons that they might get the team out for he was going to plough that day. The oxen were soon yoked and fastened to the cart in which they were to take the plough and other implements which would be needed in the labors of the day. But when the plough was brought out it was found that one of the handles needed some repair; then a chain was discovered to be missing: this was finally *looked up*. Now, said the father, fetch the iron bar, for we shall want to dig the stones which the plough may lay open. The iron bar had been lent a few days before to one of the neighbors who lived across the street, who had neglected to return it and was now from home. After hunting about his premises awhile this was also secured. Now all things seemed to be ready for a start; the oxen set forward, when the squeaking of the wheels reminded the company that they had forgotten to grease them the night before, as they had resolved to do. It will never do, said Mr L., to go to work with the wheels in such a condition; so they set to and finished this job. A full hour and a half had passed away since the oxen had been taken from the stall. Who can not see that under such management, if the cattle of Mr L. perform the same amount of work, they have a much more exhausting service than those of his neighbor, Mr F., who when about to use his team, gets every thing ready before they are taken from the crib. I think it would not be overstating to say, that on the days when they are worked, Mr L.'s cattle have upon an average two hours less time to

feed and rest than those of Mr F. Who will be surprised then to know, that though those of both are liberally fed, the team of Mr S. always looks thin, dejected and worn out, while those of Mr F. are in good condition, sprightly, and strong for labor. The last thing in getting ready for the day's work should be to put in the team: the first thing after the labors of the day are over is to take off the yoke and set the faithful oxen free. Whoever will listen to this advice and conform to it, will, whatever be his present sentiments, come to the same conclusions. B.

MAMMOTH EGGS.

Among other remarkable productions of the day, we have seen none more so than a couple of eggs—hens egg—in the office of J. S. & T. B. Skinner, of this city, (Baltimore.) They are from hens which cost five dollars each, and which are, in the body, the size of the cock of the common breed. Every egg is full of meat, to a proverb—but the eggs of the Ostrich breed contain more than double as much meat as the egg of the common barnyard fowl. This is not stated at random. One of each was weighed in the Chesapeake Bank by troy weight, on the 23d inst. The egg of "Speckle," of the Ostrich breed, weighed 3 oz. 1 dwt. 17 grains; whereas the egg of the common hen weighed but 1 oz. 8 dwt. 14 grains.—*American Farmer*.

Massachusetts Horticultural Society.

EXHIBITION OF FLOWERS.

Saturday, June 27th, 1840.

Dahlias, by Mr Ellery, of Brookline.

Bouquets, by R. Howe, Jno. A. Kenrick, Wm. Kenrick, Jno. Hovey, Hovey & Co., A. Bowditch, and S. Walker.

Roses, by Messrs Winship, of Brighton, S. R. Johnson, Wm. Kenrick, (15 varieties), R. Howe, and S. Walker.

Pinks, by S. Walker.

Cut flowers in variety from Messrs Winship, Walker, Kenrick and Howe. Jno. A. Kenrick, 5 var. of honey-suckle.

For the Committee.

S. WALKER, *Chairman*.

¶ The Essex Agricultural Society hold their annual Cattle Show and Exhibition at Georgetown, on Wednesday the 30th of September next. We have received the Society's List of Premiums, and will publish it in our next.

The communication of Mr Kenrick is too lengthy for our columns this week. It shall be commenced in our next number.

The Philadelphia Ledger says that a Yankee has invented a method of keeping hens from scratching in gardens. The plan is to tie two of the toes of one foot. The hen cannot scratch with the tied foot, and she cannot stand on that foot alone to scratch with the other.—This is the age of invention.

The Hessian fly is doing extensive injury to the wheat crops in several parts of Pennsylvania and Maryland. The southern papers complain also of the ravages of a new species of fly upon the tobacco plant. What a taste they must have.

When plants are removed in sunny weather, it is of great advantage to place a shingle or some such thing, on the south side of the plant to shade it from the mid-day sun.

BRIGHTON MARKET.—MONDAY, June 27, 1840.

Reported for the New England Farmer

At Market 345 Beef Cattle, 10 pairs Working Oxen, 15 Cows and Calves, 1450 Sheep and 200 Swine.

Prices.—Beef Cattle.—We reduce our quotations to correspond with sales. First quality, \$6 25. Second quality, \$5 75 to \$6 00. Third quality, \$5 00 to \$5 50. **Working Oxen.**—No sales noticed.

Cows and Calves.—Sales \$22, \$27, \$30, \$33, \$40, and \$45.

Sheep.—Dull. Lots were sold at \$1 33, \$1 75, \$1 88, \$2 25, \$2 50, and \$2 75.

Swine.—Lots were sold to peddle. A few were retained from 4 1-2 to 7.

125 Beef Cattle remain unsold.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded Northerly exposure, weeks ending June 21 and 28.

DORKING FOWLS.

For sale, a few pairs of pure Dorking Fowls. The stock, of which these are the produce, were procured in Dorking, County of Surrey, England. "A few breeds have a title to boast of so high and long continued a reputation as the Dorking. Upwards of fifty five years have passed, since, while resident in Surrey, I sent to Dorking for my first regular breeding-stock: they were then the ancient and superior five-clawed breed of Surrey."—*Mowbray on Poultry, 7th Edition.*

This breed attains to a large size, and the hens are the best of layers. Price \$3 per pair. Apply to

JOSEPH BRECK & CO.

June 24.

OSTRICH FOWLS.

For sale, a few pairs of this largest breed of domestic poultry. The hens are good layers and the eggs of the largest size. The male, of which these are the produce weighs more than eight pounds in common condition, and he is not quite a year old. This breed, as well as the Dorking, makes good capons. Price \$5 per pair. Apply to

JOSEPH BRECK & C

June 24.

PURE BLOOD BERKSHIRE PIGS.

The Society of Shakers at Harvard, Mass., have for sale the Pure Blood Berkshire Pigs. Also, a lot of Berkshire crossed with other Breeds, on reasonable terms at their Village.

Persons wishing to be sure of the clear Berkshire breed may rely on those they offer for sale, as they are the progeny of some of the latest imported from England.

June 24.

A Half Blooded Cream Pot Bull Calf for Sale.—Calved April, 1840. Dam, a first rate native cow, and got by Col. Jacques' Famous Bull, Don Cream Pot. This Calf is a deep red color, and strongly marked of the Cream Pot breed. Apply to

JOSEPH BRECK & CO.

Dorchester, June 21.

NOTICE.

The Rhode Island Society for the encouragement of Domestic Industry, have prepared copies of Dr Jackson's Geologist and Agricultural Report of Rhode Island, and will deliver the members each a copy gratis, by calling on B. Cranston & Co. at their Bookstore in Providence.

WILLIAM RHODES, Treasurer.

Rhode Island, June 24.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and horse, with a boy to lead, will rake on an average from 25 to 30 acres per day, with ease, and do the work well. They are coming into very general use in all parts of the country, and will, no doubt, in a few years, supersede the use of the common hand rake. There is a great advantage in this rake over all others, as the person using it does not have to stop the horse to unload the rake.

GRAIN CRADLES.

The Grain Cradle is an article which is coming into very general use in the New England States; where they were till of late but little known, although they have been in very general use in the southern and western States, for many years, and which is found to be decidedly the best mode of harvesting grain, as it is supposed one man will cradle five acres in a day when he cannot reap more than one. The difference in gathering a crop is so much in favor of cradling hereafter, and the grain cradle will become of as much use, as an implement of husbandry, as the plough now is.

There has been a very great improvement in the manufacturing of this article, they are now made on the most improved plan; the scythe is well secured and finished in a superior manner and made of the best cast steel.

SCYTHES, RAKES, &c.

The subscribers offer for sale a very extensive and complete assortment of Scythes, Rakes, &c. consisting in part of

300 dozen Phillips, Messer and Colby's superior Scythes.	
50 " Metcalf's do do.	
50 " Tall's cast steel do do.	
25 " English do do.	Grass do.
10 " do do do.	Cradle do.
10 " do do do.	Border do.
100 " Hall's Rakes, superior.	
100 " Wilder & Eddy's do do.	
200 " Common do do.	
100 " Clapp's patent Scythe Snaths.	
50 " Baker's do do do.	
100 " Common do do do.	
2500 " Austin's superior Rides.	
2000 " Common do.	
1000 " Scythe Stones.	
100 " Grain Cradles superior.	

They would respectfully call the attention of Dealers and Agriculturists to the above assortment, which consists of many of the best kinds now in use, and which they are prepared to sell at the very lowest prices.

North
publ.

(Continued from page 430.)

The distinguishing features of this division are a deep rich soil, comparatively free from stones, and very dense, luxuriant forests. The soil in the eastern part of this section is of a reddish brown color, which is imparted to it probably by the decomposed debris of the red sandstone, which is the principal rock of the Alleghany ridge. The color grows darker until in Indiana it becomes nearly black. The whole region abounds in clay which is more or less incorporated with the soil. The rocks are almost if not quite all, limestone. I do not remember of having seen a stone of any size in the western country, except of limestone, or which did not contain lime, though perhaps there may be micaceous and argillaceous rocks, which do not contain lime. From these facts we should be led to expect a soil well adapted to grain, particularly wheat, and to grass; and such is in fact the case. In Indiana, however, Indian corn generally does better than the smaller grains, which I apprehend is owing not so much to the character of the soil as to the fitness of the surface.

What is here said of the middle region will probably apply to western Virginia, to Kentucky, and perhaps to Tennessee, though as I have no personal knowledge of those States I may be mistaken.

West of the Wabash we find a country of a peculiar character. The northwest part of Indiana, nearly the whole of Michigan, Illinois, the southern half of Wisconsin, Iowa, Missouri, and the territory west to the Rocky mountains, is all a prairie country. Instead of the dense forests of the middle region, we find an immense extent of country without timber of any kind, except here and there insulated groves and narrow belts along the banks of the water courses. Timber is the general term applied to woodland in the west: thus in travelling across the prairies they speak of going from one timber to another; but yet they make a distinction between the wood in high and low situations.

The wood growing along the margin of streams and in low lands is similar to the forests in Indiana, consisting of beech, black walnut, sugar maple, sycamore, white and red oak, poplar, bass, hickory, &c., and is called particularly, *timber*; that growing upon high rolling land is chiefly burr oak, mingled in some places with white and black oak, and hickory, and such tracts are called *barrens* or *openings*. The soil of the prairies is a black sandy loam; it has no crust of vegetable mould, but the whole depth of the soil is alike, being a mechanical compound of minute particles, similar to the deposits in the estuaries of large rivers, and although a large portion of the prairies, particularly in the south, have clay underlying the soil, there is very little of the clay incorporated in the soil. The banks of the rivers and creeks are generally clay, and as far as the timber extends the soil contains a good deal of clay: this is the case also in the barrens, and it is a common remark that wherever there is timber the soil contains more or less clay. In the northern parts of Illinois and in Wisconsin, the subsoil is generally gravel, yet the character of the top soil is very nearly the same as in the south, though as might be expected, it is rather drier, both because the gravel absorbs more water, and the surface is more rolling.

The prairies in the southern counties are in general called level, but they are not strictly so: there are slight undulations, but the difference of levels does not amount to many feet. The water drains off from the higher portions into the hollows, where

it remains until it is evaporated, and these places are the famous sloughs, of which we hear so much, and in the wet seasons they are very ugly places to pass, as I have reason to know. As we travel northward the surface becomes more undulating or rolling, and the sloughs are more narrow.

On the margins of rivers there are in many places considerable tracts of natural meadow: these tracts are called bottoms: the soil is similar to the high prairie, but lying low and being overflowed at every freshet, it is moist, but not marshy. These bottoms are too low to admit of cultivation, but are valuable for grass: there are other tracts of small extent which are marshy.

We often hear extravagant stories about the grass upon the prairies; it has been represented as growing as tall as a man upon horseback, and the idea is prevalent that the prairies produce enormous burthens of excellent grass, and many writers have taken much pains to establish such an idea—but it is not so. Upon the little patches of low bottoms, particularly about the Illinois river, there is indeed some tall grass resembling a little the common blue-joint of New England meadows, but coarser and much inferior for fodder. The grass of the bottom land generally and of the sloughs, is something like the common grass of our wet meadows, though I think generally of better quality for hay. It rarely grows more than one and a half or two feet high, and the average quantity to an acre cannot exceed a ton of cured hay, and the extreme is not more than two tons. The high prairie is not well adapted to grass. That which does grow, when young is very tender and affords excellent pasture: it comes to maturity early and is then a coarse harsh grass and of little value: its height is from eight to ten inches when fully grown, and an extreme crop will not exceed half a ton to the acre. I have seen many fields of cultivated grass, both timothy and red top, and when highly manured the yield is for two or three years on the best prairie a ton to the acre: without manure the yield does not exceed half a ton. This surprised me exceedingly, for the same soil often yields forty bushels of wheat, and in the east we expect a large crop of hay where we obtain a large crop of grain. I account for a different result in the west in this way: the soil as before stated is sandy, and the long droughts in summer parch up the surface exceedingly, and grasses which do not root deep suffer from the drought; but grain comes forward early, and the thick growth protects the earth longer than the common grasses, and when it does dry the straw has come to maturity. Corn and other plants which root deep are not injured by the summer droughts, and hence I think that red clover would succeed well; but I never saw a field of it upon prairie, nor have I seen any one who has tried it. The bottoms may be converted into valuable meadows by simply burning off the wild grass in the spring and sowing grass seed.

From these facts it is evident that Illinois will not be a good grazing country, but is admirably adapted to the production of grain. The scarcity of springs and rivulets is another obstacle to the raising of stock. The southern part of the State is generally admitted to be rather destitute of water, but the northern part of the State is said to be well watered, but it is so only in comparison with the south. At present while the whole country almost lies common, there is no difficulty in keeping large stocks of cattle, but when the country becomes filled up and the farms fenced, the case will be dif-

ferent. There are very few farms which have a permanent supply of water for stock.

(Concluded in our next.)

Virtue.—There is but one pursuit in life which it is in the power of all to follow and all to attain the object. It is subject to no disappointments, since he that perseveres makes every difficulty a cause of advancement, and every contest a victory. This is the pursuit of virtue.

Alteration and decay are written on every thing human. Nature is built of changes; but her bright scenes are withdrawn only to be replaced by others still brighter. Life is a flower garden, in which new blossoms are ever opening as fast as others fade.

BONE MANURE.

The subscriber informs his friends and the public, that after ten years experience, he is fully convinced that ground bones form the most powerful stimulant that can be applied to the earth as a manure.

Orders for Bone Manure or Oyster Shell Lime, left at the Bone Mill, near Tremont road, in Roxbury, at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, or through the Post Office will meet with prompt attention.

NAHUM WARD.

Week's Treatise on Bees

JOSEPH BRECK & CO.

For sale by

April 15.

NEW AMERICAN GARDENER.

FOURTEENTH EDITION.

The New American Gardener, containing practical directions on the culture of Fruits and Vegetables, including Landscape and Ornamental Gardening, Grape Vines, Silk Strawberries, &c., by Thomas G. Fessenden, late editor of the New England Farmer. For sale by JOSEPH BRECK & CO., 51 and 52 North Market Street. May 13.

CARNATION SEED.

The Subscribers have received from Rotterdam, a small quantity of extra fine Carnation Seed, saved from one hundred choice varieties, which they offer at 25 cents per paper. We have tried it, and find that it vegetates freely. It cost us 30 guilders per ounce, and from the representation made, no doubt will give satisfaction to those who may be disposed to try it. We have also very fine carnation seed at 12½ cents per paper. The seed may be sown with good success any time in May or June. JOSEPH BRECK & CO.
